NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.

21 **Abstract**

22 **Introduction:**

23 Insufficient physical activity is a significant contributor to non-communicable disease
24 amongst the global population. Insufficient physical activity is directly linked with reduced
25 cardiorespiratory fitness (CRF). CRF is as strong a predictor of mortality as well-established
26 risk-factors such as smoking, hypertension, dyslipidaemia, and type 2 diabetes mellitus,
27 however, it remains the only major risk factor not routinely assessed in primary health care
28 settings. The aim of this review was to assess the validity and reliability of existing
29 submaximal tests of CRF which can be employed in a standard medical consultation for the
30 estimation of CRF and physical function in adults.

31 **Methods:**

32 A systematic review of the scientific literature was undertaken to find all studies reporting
33 the reliability and/or validity of submaximal tests of CRF and physical function. Studies
34 published up to 12 January 2023 were included in the search of the Medline, Embase,
35 Cinahl, SPORTdiscus, Cochrane library, Informit Health and Web of Science databases. Risk
36 of bias was assessed using the JBI critical appraisal checklist for analytical cross-sectional
37 studies. Data including reliability of the submaximal protocols as measured by test-retest
38 Pearson's r (r) or Intraclass co-efficient (ICC); and validity as measured by the correlation
39 between the submaximal protocol results and the graded exercise test results (r) was
40 extracted. Meta-analyses were performed to determine the overall mean r of the
41 correlation coefficients.

42

43 **Results:**

44 In total 1754 studies were identified. Following screening, 143 studies including 15,760
45 participants were included. All clinical tests included in meta-analysis demonstrated strong
46 reliability. The Siconolfi step test ($r=0.81$), Incremental shuttle walk test ($r=0.768$) and 1-
47 minute sit-to-stand test ($r=0.65$) demonstrated strongest validity following meta-analysis.

48 **Conclusion:** Based on the validity of the tests outlined, these can be used as an acceptable
49 method of estimating VO₂peak in a broad population, without the cost and access issues of
50 formal GXT.

51

52

53 **1. Introduction**

54 Insufficient physical activity is a significant contributor to non-communicable disease
55 amongst the global population, including obesity, many types of cancer, metabolic syndrome
56 and cardiovascular disease, as well as all-cause mortality (1). In Australia, two thirds of adults
57 report as overweight or obese and over half of Australian adults do not participate in
58 sufficient physical activity to meet the Australian government's recommended *Physical*
59 *Activity and Sedentary Behaviour Guidelines for Adults* (2, 3). The economic cost of physical
60 inactivity to the Australian health system is estimated at around \$850 million annually,
61 accounting for between 38,400 and 174,000 disability adjusted life years (DALYs) per year (4).

62

63 Insufficient physical activity is directly linked with reduced cardiorespiratory fitness (CRF) and
64 reduced physical function (1, 5). Those with low cardiorespiratory fitness face a 70% higher
65 risk of all-cause mortality and a 56% greater risk of cardiovascular disease mortality (5). CRF
66 is as strong a predictor of mortality as well-established risk-factors such as cigarette smoking,
67 hypertension, high cholesterol, and type 2 diabetes mellitus (T2DM) (6). Evidently,
68 measurement of CRF and tracking of progress towards improving CRF should become a
69 standard part of clinical consultations, as is standard of care with hypertension, dyslipidaemia,
70 diabetes monitoring and smoking cessation (6).

71

72 Whilst the cost of inactivity is high, there is significant potential for improvement across global
73 populations. CRF can be measured directly via graded exercise testing (GXT) and expressed as

74 maximal oxygen consumption (VO₂max), or estimated from peak work rate achieved in GXT
75 (VO₂peak) or through submaximal testing via algorithm or correlation. Oxygen consumption
76 can be converted to metabolic equivalents (MET), with most activities having an estimated
77 MET value(7). There is no 'lower threshold' for the relative risk reduction benefit of regular
78 exercise (1). For example, a 20% reduction in mortality attributable to cardiac causes is
79 observed for every 1-MET increase in exercise capacity (8). Incidence of falls can be reduced
80 by more than 50% with simple exercise interventions (9). To date, to our knowledge, no study
81 has assessed the validity and reliability of submaximal testing that can be performed in a
82 standard medical consultation, limiting the utility of CRF within clinical consultations.

83

84 CRF is recognised as an important marker of functional ability and cardiovascular health;
85 however, it remains the only major risk factor not routinely assessed or regularly monitored
86 in primary health care settings (10). The direct assessment of cardiorespiratory fitness via
87 maximal testing is costly, requires equipment and trained personnel, as well as demanding a
88 maximal effort which is frequently unattained in non-athletic participants (11, 12).
89 Consequently, a large number of submaximal exercise protocols have been developed,
90 involving stationary cycling, running, walking, arm ergometry and stepping; however, time,
91 space or equipment requirements deem many inappropriate for regular medical clinical utility
92 ((12)). Regular and routine clinical testing of physical function and CRF would allow clinicians
93 to determine the CRF and functional capacity of their patients to aid in exercise prescription
94 and counselling, whilst providing the patient with motivation and accountability to improve
95 their health outcomes.

96

97 The aim of this review was to assess the validity and reliability of existing submaximal tests of
98 CRF which can be employed in a standard medical consultation for the estimation of CRF and
99 physical function.

100

101

102 **2. Methods**

103 **2.1 Review Strategy**

104 A systematic review of the scientific literature was undertaken to find all studies reporting
105 the reliability and/or validity of submaximal tests of CRF and physical function. The study was
106 registered with Prospero registration CRD42022368963 and protocol can be accessed via
107 https://www.crd.york.ac.uk/prospero/display_record.php?RecordID=368963. Studies
108 published up to 12 January 2023 were included in the search of the Medline, Embase, Cinahl,
109 SPORTdiscus, Cochrane library, Informit Health and Web of Science databases . The broad
110 search strategy involved the following terms, limited to English language: ‘Physical function
111 test’ OR ‘exercise test’ OR ‘graded exercise test’ OR ‘GXT’ OR ‘fitness test’ OR ‘squat test’ OR
112 ‘sit to stand’ OR ‘step test’ AND ‘exercise tolerance’ OR ‘exercise capacity’ OR
113 ‘cardiorespiratory fitness’ OR ‘aerobic fitness’ OR ‘aerobic capacity’ OR ‘time to fatigue’ AND
114 ‘validity’ OR ‘valid’ OR ‘reliable’ OR ‘reliability’.

115

116 **2.2 Eligibility criteria**

117 Eligible studies met the following inclusion criteria: (1) English language; (2) published any
118 time from database establishment until 12 January 2023; (3) investigating a clinical test of
119 physical function in (4) participants 18 years of age or older. In order to ensure that studies
120 relevant to the aim of this review were analysed, particularly with regards to tests applicable
121 in a clinical setting, studies were excluded on the following basis: (1) Study type - case reports,
122 not original research, not in English language, conference proceedings; (2) *Clinical* test –
123 equipment requirement beyond scope of that available in a standard Australian medical clinic
124 (e.g. a step, chair or stopwatch), duration greater than ten minutes to administer, expense or
125 technical expertise required to administer; (3) Validity and reliability descriptors – no relevant
126 statistical analysis; (4) Outcomes of interest – no mention of one or more of heart rate, time
127 to fatigue, VO₂ peak, VO₂ max, METs, number of repetitions.

128

129 **2.3 Study selection**

130 Studies were selected based on the predetermined inclusion and exclusion criteria.
131 Assessment of study eligibility was performed using Covidence systematic review software
132 (Veritas Health Innovation, Melbourne, Australia, available at www.covidence.org) and
133 conducted independently by two reviewers. Studies were excluded based on title and
134 abstract and the reason for exclusion was recorded, with any disagreement resolved by a
135 third reviewer. Full texts of the remaining studies were assessed by two reviewers, with all
136 authors discussing any disagreements to achieve a consensus view.

137

138 **2.4 Data extraction**

139 One author extracted all relevant data from included studies using a standardised form, with
140 quality control performed on a random sample of 10 papers by two other reviewers. Data
141 extracted included author, year and location of publication; population studied including
142 mean age(standard deviation)[SD], gender split, BMI(SD) and medical condition (where
143 relevant to the study) of participants; inclusion and exclusion criteria; sub-maximal protocol
144 undertaken; graded exercise test undertaken; reliability and validity statistics; and other
145 outcome measures of note (HR, VO₂peak, RPE, 6MWD, sit-to-stand repetitions). The primary
146 outcomes of interest were reliability of the submaximal protocols as measured by test-retest
147 Pearson's r (r) or Intraclass co-efficient (ICC); and validity as measured by the correlation
148 between the submaximal protocol results and the graded exercise test results (r).

149

150 **2.5 Risk of bias assessment**

151 The risk of bias of included studies was assessed using the JBI critical appraisal checklist for
152 analytical cross sectional studies (JBIC) (13). This checklist assesses specific domains of the
153 studies to determine the potential risk of bias that can be answered with yes, no, or unclear.
154 If the answer was yes, the question was assigned a score of 1. If the answer was no, unclear,
155 or not applicable, it was assigned a score of 0. Studies with a score of 7-8 were deemed low
156 risk of bias, 4-6 moderate and 0-3 high. No studies were excluded on the basis of risk of bias
157 assessment.

158

159 **2.6 Data synthesis**

160 Meta-analyses were performed to determine the overall mean r of the correlation
161 coefficients. Data including reliability of the submaximal protocols as measured by test-retest
162 Pearson's r (r) or Intraclass co-efficient (ICC); and validity as measured by the correlation
163 between the submaximal protocol results and the graded exercise test results (r), was pooled
164 using a random-effects model. Jamovi Version 2.2 (Computer Software retrieved from
165 <https://www.jamovi.org>) was used for statistical analysis.

166

167 **3. Results**

168 **3.1 Paper identification**

169 In total 1754 studies (title and abstract) were identified following deletion of duplicates
170 ($n=80$). Following screening, 1466 were excluded, with 283 full texts obtained for further
171 eligibility assessment. 143 full-text papers were included for review (*Figure 1*).

172 **Fig 1: PRISMA diagram of included studies**

173 **3.2 Sub-maximal test characteristics**

174 The 143 included papers studied 49 different clinical tests of physical function. 75 studies
175 assessed the 6-minute walk test (6MWT) (14, 15, 16, 17, 18, 19, 20, 21, 22, 23, 24, 25, 26, 27,
176 28, 29, 30, 31, 32, 33, 34, 35, 36, 37, 38, 39, 40, 41, 42, 43, 44, 45, 46, 47, 48, 49, 50, 51, 52,
177 53, 54, 55, 56, 57, 58, 59, 60, 61, 62, 63, 64, 65, 66, 67, 68, 69, 70, 71, 72, 73, 74, 75, 76, 77,
178 78, 79, 80, 81, 82, 83, 84, 85, 86, 87). Fifteen studies analysed the incremental shuttle walk
179 test (ISWT) (18, 37, 56, 58, 68, 88, 89, 90, 91, 92, 93, 94, 95, 96, 97). The 1-minute sit to
180 stand(1mSTS) was studied in eight papers, the 6-minute step test (6MST) in seven, 'timed up

181 and go test' (TUGT) in six, and the Siconolfi step test (SST) in five (70, 80, 86, 87, 98, 99, 100,
182 101, 102, 103, 104, 105, 106, 107, 108, 109, 110, 111, 112, 113, 114). Seven tests were studied
183 in three papers, five tests were studied twice and fifty once. A degree of heterogeneity existed
184 amongst the exact test protocols for many of the clinical tests described by the same name,
185 however they were extracted as named by the authors.

186

187 **3.3 Graded exercise test characteristics**

188 A graded exercise test was included in 71 of the 143 studies included. Of these, 38 included a
189 cycle ergometry based graded exercise test, with one additional study recumbent cycle
190 ergometry. There were 32 treadmill based graded exercise tests included.

191

192 **3.4 Quality assessment**

193 Table 1 provides a summary of how each individual paper rated per the JBI critical appraisal
194 checklist. Fifty (34.9%) included studies scored 7 or 8 to be deemed low risk of bias. Eighty-
195 three (58.2%) had a moderate risk, and 10 (6.9%) high risk of bias.

196 **Table 1:** Quality assessment JBI critical appraisal checklist.

197 **3.4 Participant characteristics**

198 In total 15,670 participants were included across the 143 studies. The smallest study included
 199 5 participants (39), the largest 5287 (115). Six studies reported no sex distribution, of the
 200 studies reporting, 5588 participants were female (approximately 37%).

201

202 **3.4.1 Special populations**

203 Thirty-nine studies included no specific medical condition inclusion criteria. Participants
 204 selected for respiratory conditions (including COPD, restrictive lung disease and sleep
 205 apnoea) were studied in 29 papers. Cardiovascular conditions were the focus in 21.

206 Musculoskeletal, neurological, auto-immune, psychological and age based sub-groups were
207 also studied in the remaining papers.

208

209 **3.5 Measures** – All included studies reported clinical test performance correlation
210 with GXT performance in terms of Pearson’s r. Test-retest reliability was reported in terms of
211 ICC or Pearson’s r.

212

213 **3.6 Clinical tests**

214 **3.6.1 Walk test protocols**

215 **3.6.1.1 6MWT**

216 A total of 71 included papers studied the 6MWT, with 21 cohorts from a total of 19
217 studies meeting inclusion in the meta-analysis for validity with correlation between 6MWT
218 and directly measure VO₂ peak on GXT results included. In total these studies included 1836
219 participants with a broad range of medical conditions. Overall the 6MWT demonstrated
220 moderate positive correlation with performance on the graded exercise test (GXT), with
221 $r=0.581$ (figure 2). The largest study, Shulman et al studied 574 adults older than 40 years
222 awaiting elective non-cardiac surgery, and all participants had at least one cardiac risk factor,
223 with low positive correlation overall $r=0.36$ (28). Kervio et al’s study of 24 patients of mean
224 age 65 with NYHA grade II or III congestive cardiac failure (CCF) found the strongest
225 association with GXT performance $r=0.8$ (16). Granger et al’s study of a cohort of 20 male lung
226 cancer patients found the lowest correlation, $r = 0.24$ (58). Pankoff et al’s study of a

227 fibromyalgia cohort pre and post exercise program found the pre-exercise cohort correlation
228 of $r=0.33$ (30). The only included study of a ‘healthy’ population, Hong et al, involved a cohort
229 of 73 healthy adults (37male, 36 female), mean age 30.8 who were screened for
230 cardiorespiratory, orthopaedic and musculoskeletal conditions prior to participation, and
231 found a correlation between 6MWT and GXT performance of $r=0.671$. Overall four studies of
232 five CCF populations were included, with correlations ranging from 0.54 to 0.8 (16, 17, 23,
233 25). Two studies analysed pulmonary artery hypertension populations, with strong
234 correlation noted $r=0.77$ and $r=0.72$ (18, 19).

235 **Fig 2:** 6MWT performance vs GXT correlation forest plot

236 Test-retest reliability of the 6MWT was studied in 27 studies of 1506 participants. In meta-
237 analysis of 22 studies of 965 patients, with reliability measured by ICC, an overall ICC of 0.95,
238 indicating strong test-retest reliability. For the remaining five studies of 541 participants
239 $r=0.93$.

240 **Fig 3:** 6MWT reliability (pearson’s r) forest plot

241 **Fig 4:** 6MWT reliability (ICC) forest plot

242

243

244 **3.6.1.2 ISWT**

245 Fourteen studies included the ISWT, with 5 studies meeting inclusion in the meta-
246 analysis for validity (18, 58, 88, 92, 93, 94). In total these studies included 114 participants.
247 Overall the ISWT demonstrated strong positive correlation with performance on GXT, with

248 $r=0.768$. De Camargo et al's study of a cohort of 75 patients with bronchiectasis was the
249 largest cohort, with $r=0.72$ compared with a cycle ergometer GXT (88). Barbosa et al's study
250 of 50 asthma patients demonstrated the strong validity of the ISWT in this cohort at $r=0.9$
251 (93). Irisawa et al's study of 19 patients with pulmonary artery hypertension (PAH) also
252 demonstrated the strong validity, $r=0.866$, with participants recording the lowest mean ISWT
253 distance (ISWD) at 359.4m, compared with 441m and 410m for the de Camargo and Granger
254 cohorts respectively (18, 58, 88). Granger et al studied an all-male population of 20 non-small
255 cell lung cancer patients with $r=0.61$ (58).

256 **Fig 5:** ISWT performance vs GXT correlation forest plot

257 Test-retest reliability was very high across the five studies meeting inclusion criteria for
258 reliability, with $ICC=0.94$ from 284 participants (37, 63, 88, 93, 94).

259 **Fig 6:** ISWT reliability (ICC) forest plot

260

261 **3.6.1.3 2-minute walk test (2MWT)**

262 In total four papers included the 2MWT, however an insufficient number met the
263 inclusion criteria to be meta-analysed. Two studies assessed the 2MWT performance
264 correlation with GXT. Beckerman et al studied 141 patients with multiple sclerosis, finding
265 poor validity $r=0.44$ (116). Leung et al studied 45 patients with moderate to severe COPD,
266 finding a moderate correlation $r=0.56$ (66).

267 Two studies found strong test-retest reliability for the 2MWT, with again insufficient
268 numbers included to be meta-analysed. Vancampfort (66) and Leung respectively found
269 $ICC=0.96$ and $ICC=0.99$ (66, 83).

270

271 **3.6.2 Step tests**

272 **3.6.2.1 Siconolfi step test (SST)**

273 Three studies met the inclusion criteria for validity meta-analysis, with an overall
274 population of 138 patients included and a strong correlation of $r=0.81$ established. Lemanska
275 et al's study of 66 men with prostate cancer was the largest included, with the weakest
276 correlation at $r=0.69$ (112). Siconolfi's original study of 48 healthy adults found a correlation
277 of $r=0.92$ with a cycle ergometer GXT (114). Cooney et al found a strong correlation of $r = 0.79$
278 in 24 patients with rheumatoid arthritis (RA)(111).

279 **Fig 7: SST vs GXT correlation forest plot**

280 Reliability was very strong for the SST across 120 patients from 3 studies, with ICC =
281 0.92 demonstrating good test-retest reliability (111, 112, 113).

282 **Fig 8: SST reliability (ICC) forest plot**

283 **3.6.2.2 Chester step test (CST)**

284 Two included studies assessed the validity of the Chester step test (117, 118). Sykes
285 et al assessed 68 healthy adults and found strong correlation between CST and GXT result,
286 $r=0.92$, with a standard error of predicted estimate of aerobic capacity (VO_{2peak})
287 $3.9mlO_2/kg/min$ (118). Reed et al in their 2020 study of 47 cardiac rehabilitation participants
288 also found high moderate correlation $r=0.693$ (117). Their CST involved adjustment of step
289 height within a range between 15-30cm "suitable to participants functional level". Of note

290 the Sykes population achieved a mean VO₂Max of 52.1mlO₂/kg/min, suggesting a good level
291 of CRF, and validity in a population with good levels of fitness.

292 Neither study included correlation reliability statistics. Sykes et al (119) reported good
293 test-retest reliability using the Bland and Altman method, finding a mean difference of -
294 0.7mlO₂/kg/min (119).

295

296 **3.6.2.3 6 minute step test (6MST)**

297 Two studies correlated GXT performance with 6MST performance to determine
298 validity, Giacomantonio et al found a strong correlation with GXT of $r=0.88$ in a population of
299 28 participants with two or more CVD risk factors, whereas Marinho et al found a weaker
300 $r=0.59$ in 27 heart failure with reduced ejection fraction (HFrEF) patients (64, 109). Five
301 studies of a total of 194 participants found good reliability, ICC = 0.97 across varied
302 populations of healthy adults, an obstructive sleep apnoea cohort, patients with COPD and
303 the above CVD and HFrEF cohort (Figure 9) (64, 72, 105, 108, 109).

304 **Figure 9: 6MST reliability (ICC) forest plot**

305 **3.6.2.4 2 minute step test (2MST)**

306 One study assessed validity of the 2MST, finding a moderate correlation ($r=0.54$) with
307 GXT performance, in a population of 36 Australian adults (120). The 2MST has demonstrated
308 strong reliability (ICC>0.9) in two studies of 68 participants (121, 122)

309 **3.6.2.4 YMCA step test (YMCAST)**

310 Kieu et al demonstrated the validity of a YMCAST equation developed and validated
311 for a Korean population aged 19-64 years, in a population of Vietnamese participants, with a
312 correlation of 0.8 with treadmill VO₂max (123). Santo et al (124) also earlier demonstrated
313 the validity of the YMCAST in a cohort of healthy participants via recovery heart rate
314 correlation with treadmill GXT VO₂max (124), demonstrating a correlation of 0.58 using an
315 adjustable step height based on participant's height which may limit clinical applicability,
316 however remains a potentially valid predictor of CRF.

317 No included studies assessed the reliability of the YMCAST.

318 **3.6.2.5 Canadian aerobic fitness test (CAFT)**

319 The CAFT was assessed in two studies describing three healthy cohorts of 60 participants
320 in total (125, 126). Moderate correlation between CAFT performance and GXT performance
321 was determined, $r=0.645$.

322 No test re-test reliability was established in included studies.

323

324

325 **3.6.3 Squat tests**

326 **3.6.3.1 1 minute sit to stand test (1MSTST)**

327 In total ten studies involving the 1MSTST were included, with three studies meeting the
328 inclusion criteria for validity meta-analysis. Four studies of a total of 70 participants found an
329 overall correlation of $r=0.649$ (98, 99, 101, 103). Radtke 2016, and Radtke 2017 studied a
330 population with cystic fibrosis in pulmonary rehabilitation, with moderate and weak to

331 moderate correlation between the STS repetitions completed and VO₂peak on GXT (98, 99).
332 Gephine et al studied of a population with COPD demonstrated moderate to strong
333 correlation between STS repetitions and VO₂peak on GXT at 0.71 (101).

334 **Fig 10: 1MSTST correlation with GXT forest plot**

335 Five studies including 185 participants reported the reliability of the 1MSTST as strong,
336 with an ICC on meta-analysis of 0.949 (80, 99, 100, 103, 127).

337 **Fig 11: 1MSTST reliability forest plot**

338

339 **3.6.3.2 30 second sit to stand test (30STST)**

340 No study of the validity of the 30STST meeting our inclusion criteria was included.

341 Three studies, Hansen et al (2018) in a cohort of patients with COPD and Ozcan-Kahraman
342 et al (2020) a cohort of patients with pulmonary hypertension, and Lázaro-Martínez et al
343 (2022) a cohort of patients with obesity, of a total of 147 participants demonstrated strong
344 reliability, with an ICC of 0.94 and 0.95, and $r=0.91$ respectively (84, 87, 128).

345 **3.6.3.3 The 5 repetition sit to stand test (5STST)**

346 No study of the validity of the 5STST meeting our inclusion criteria was included.

347 Meta-analysis revealed ICC=0.91 demonstrating strong reliability. The 3 included studies
348 demonstrated strong reliability individually. Curb et al (2006) studied 210 healthy
349 participants, and found an ICC=0.8 (71). Jones et al (2013) studied 475 participants with COPD
350 and found very strong reliability, an ICC of 0.97 (96). De Melo et al (2022) assessed reliability
351 in 142 ICU patients at discharge (129).

352 **Fig 12:** 5STST reliability (ICC)

353

354 **3.6.3.4 Ruffier-Dickson squat test (RDST)**

355 One study of 40 healthy adults, performed by Guo et al found a correlation of 0.82
356 between a model incorporating test performance as quantified using participants' height, sex,
357 age and resting, immediate post-test and one minute post-test HR, and GXT VO₂max (130).

358 Sartor et al (2016) found the RDST demonstrated good reliability in a population of 81
359 healthy adults (12). Reliability was calculated measuring both HRpeak (ICC = 0.86) and via the
360 Ruffier-Dickson Index (RDI), incorporating resting, post-test and one minute post-test HR.

361

362 **3.6.4 Others**

363 **3.6.4.1 Timed up and go test (TUGT)**

364 No included study of the validity of the TUGT met our inclusion criteria.

365 Four studies including a total of 417 participants demonstrated strong reliability, with a
366 meta-analysis ICC of 0.94 (35, 86, 87, 90). This population included health adults (Spagnuolo
367 et al), a cohort of patients with pulmonary hypertension (Ozcan-Kahraman et al), a cohort of
368 patients with Down syndrome (Cabeza-Ruiz et al) and a CCF cohort (Hwang et al)(35, 86, 87,
369 90).

370 **3.6.4.2 1RM leg press**

371 Three studies analysing the 1RM leg press met the inclusion criteria, however none
372 included reliability or validity statistics relevant to this review (75, 81, 131).

373

374

375 **4. Discussion**

376 The purpose of this review was to provide clinicians with information regarding the validity
377 and reliability of submaximal tests of CRF that can be employed in a brief primary health care
378 consultation with equipment that is readily available. This review included 143 studies of 49
379 clinical tests. Diverse populations of 15,670 total participants were included from studies
380 meeting the inclusion criteria, as guided by the aims of the broad review, with a view to
381 maintaining clinical relevance and applicability. Overall reliability of all tests included in meta-
382 analyses were strong. Strongest validity was found for the SST, ISWT and 1MSTST on meta
383 analysis.

384

385 **4.1 Reliability**

386 This review provides strong evidence for the reliability of the included clinical tests. The test-
387 retest reliability of all included tests was high on meta-analysis. Meta-analysis revealed the
388 6MST was the most reliable test, however overall, all studies meta-analysed had a reliability
389 of >0.9, and there was little difference between them. Of the studies included but in
390 insufficient number to meta-analyse, good reliability was demonstrated for the 30STST, 5STST
391 and RDST (12, 71, 84, 87, 96, 128, 129). The high test-retest reliability of the majority of the

392 tests suggests they can be used to monitor changes in CRF over time as the results are
393 evidently repeatable.

394

395 **4.2 Validity**

396 This study has demonstrated moderate to strong evidence regarding the efficacy of a variety
397 of clinical tests to estimate CRF in adults. Amongst those included in meta-analysis, the
398 Siconolfi step test demonstrated strongest validity from three studies of 138 participants of
399 varied populations, including those with oncological and rheumatological conditions, as well
400 as a healthy population (111, 112, 114).

401

402 Overall the walking tests, whilst the most studied, demonstrated poorer validity than the step
403 or squat based tests. A high proportion of the included studies assess populations with
404 generally poorer CRF as the test was intended, however the overall meta-analysis result
405 supports the well documented ceiling effect of the 6MWT, and limiting the clinical
406 applicability to the broader population (132, 133). This result supports that it may have more
407 clinical utility in the rehabilitation setting, involving participants with lower VO₂ peak. The
408 ISWT demonstrated good validity and reliability on meta-analysis across five studies, and
409 given this should be considered by clinicians (18, 134).

410

411 Step tests demonstrated good validity across studies of diverse populations, and have good
412 clinical translation potential having to date been investigated to a lesser extent than walk
413 tests. Of individual included studies, Sykes' Chester step test paper demonstrates the

414 strongest correlation with CRF(118). This may suggest that tests relying on HR measures
415 conducted during test are superior to post/HR recovery based tests, and warrants further
416 investigation. The three studies investigating the Siconolfi step test demonstrated highest
417 correlation on meta-analysis, but with only 133 participants total, further investigation is
418 warranted to further demonstrate the test's value to the clinician(111, 112, 114). The 2MST
419 demonstrated only moderate correlation with GXT CRF in the single included study, which
420 may suggest there is insufficient duration to differentiate CRF levels in a well population (120).

421

422 Of the included squat tests, only one, 1MSTST, included sufficient data for meta-analysis.
423 Seventy participants completing the 1MSTS with a moderate to strong correlation with CRF.
424 The single papers were contrasting in their correlation with GXT, such as that of Guo et al
425 (130)(RDST) demonstrated the RDST has good validity (0.82) using the author's predictive
426 model, however Diaz-Balboa's (135) paper (30STST) demonstrated poor to moderate
427 correlation – perhaps highlighting squat tests' perceived limitations of relying more heavily
428 on patients functional status, and reliance on HR recovery (130, 135).

429

430 **4.3 Risk of bias**

431 Overall quality of included studies was good, with high quality reporting to allow scientific
432 replication. The vast majority of papers meta-analysed were moderate to low risk of bias,
433 providing confidence that the results were unbiased. Many studies didn't report or control
434 for confounding factors, which may have influenced outcomes in some cases. In order for

435 further adaptation of clinical tests of CRF in clinical practice, larger high-quality studies
436 controlling confounding factors must be undertaken.

437

438

439 **4.4 Strengths and limitations**

440 The aim of this meta-analysis was to aggregate a wide array of populations and submaximal
441 tests of CRF to maximise clinical application. Omission of studies of tests longer than 10
442 minutes, and requiring minimal but not the absence of equipment increases the risk of bias,
443 and may have excluded highly relevant studies. This however allowed the goal of maintaining
444 a clinical applicability lens to be met. The comparison between studies may have been limited
445 by the heterogeneity of GXT protocols, as has been discussed by authors previously, however
446 with a view to pragmatism, GXT performance was taken at face value from the included
447 studies (136, 137). The selection criteria applied included only adult data in the analysis, and
448 where papers included paediatric participants, adult data were extracted where possible and
449 the study included, however in some cases the adult data could not be extracted in isolation
450 and so that data set excluded, potentially impacting overall study results. The review included
451 only English language papers, potentially excluding relevant studies. By design, this study
452 included a broad population and large number of clinical tests which can be utilised in a
453 standard primary care consultation. Further research is warranted into the applicability of
454 valid and reliable clinical tests in specific populations.

455

456

457

458 **5. Conclusion**

459 The safe, cost-effective and accurate assessment and regular monitoring of CRF in the primary
460 health care setting presents the clinician with the opportunity to personalise exercise
461 prescription and counselling for their patient, whilst providing the patient with motivation
462 and accountability to improve their health outcomes. This review has identified a number of
463 submaximal tests of CRF which can be employed in a standard medical consultation. The SST
464 and CST demonstrate their potential for clinical translation with further investigation in larger
465 populations. The ISWT appears superior to the 6MWT and should be considered by clinicians.
466 Based on the validity of the tests outlined, these can be used as an acceptable method of
467 estimating VO₂peak in a broad population, without the cost and access issues of formal GXT.
468 The high test-retest reliability of the majority of the tests suggests they can be used to
469 monitor changes in CRF over time. Further research is needed to optimise the translation of
470 research-based exercise testing into regular clinical practice.
