36 **Abstract**

37 In autoimmune Type 1 diabetes (T1D), immune cells progressively infiltrate and destroy the islets
38 of Langerhans – islands of endocrine tissue dispersed throughout the pancreas. However, it is
39 unclear how this process, called ‘insulinitis’, develops and progresses within this organ. Here, using
40 highly multiplexed CO-Detection by indEXing (CODEX) tissue imaging and cadaveric pancreas
41 samples from pre-T1D, T1D, and non-T1D donors, we examine pseudotemporal-spatial patterns
42 of insulinitis and exocrine inflammation within large pancreatic tissue sections. We identify four
43 sub-states of insulinitis characterized by CD8⁺T cells at different stages of activation. We further
44 find that exocrine compartments of pancreatic lobules affected by insulinitis have distinct
45 cellularity, suggesting that extra-islet factors may make particular lobules permissive to disease.
46 Finally, we identify “staging areas” - immature tertiary lymphoid structures away from islets
47 where CD8⁺T cells appear to assemble before they navigate to islets. Together, these data
48 implicate the extra-islet pancreas in autoimmune insulinitis, greatly expanding the boundaries of
49 T1D pathogenesis.

55 Main

56 In Type 1 diabetes (T1D), autoimmune insulinitis drives the progressive destruction of insulin-
57 producing β -cells, resulting in a critical requirement for exogenous insulin. T1D affects over 8
58 million individuals world-wide with an estimated half-a-million new diagnoses each year (Gregory
59 et al. 2022).

60 Recently, the first immunotherapy for delaying T1D onset teplizumab (a human anti-CD3
61 monoclonal antibody) was approved by the US Food and Drug Administration (FDA) (Hirsch
62 2023). However, this treatment and other immunotherapies only benefit some patients for
63 reasons that are unclear (Herold et al. 2013; Perdigo et al. 2019; Herold et al. 2019; Pescovitz
64 et al. 2009; Orban et al. 2011; 2014; Bluestone, Buckner, and Herold 2021). A better
65 understanding of T1D pathogenesis is essential to building on this success.

66 T1D pathogenesis encompasses immune infiltration of the islets, also known as ‘insulinitis’, and
67 inflammation of the non-islet pancreas. Insulinitis has been extensively investigated and the major
68 cell types associated with β -cell killing have been identified; however, any understanding of how
69 the inflammation in non-islet pancreas contributes to insulinitis is lacking.

70 One of the challenges of studying human T1D pathology is the availability of suitable tissue
71 samples. Obtaining pancreatic biopsies raises the risk of surgical complications and the
72 progressive nature of T1D would necessitate serial, longitudinal studies over time, which is
73 prohibitive (Krogvold et al. 2014). Fortunately, the Juvenile Diabetes Research Foundation (JDRF)
74 Network for Pancreatic Organ Donors with Diabetes (nPOD) have provided human pancreatic
75 tissues from cadaveric donors for this study (Campbell-Thompson et al. 2012; Pugliese et al.
76 2014). nPOD has enabled substantial progress towards characterizing the cell types comprising
77 insulinitis and extra-islet inflammation (Wilcox et al. 2016; Arif et al. 2014; Leete et al. 2016;
78 Martino et al. 2015).

79 The development of highly multiplexed tissue imaging technologies has empowered these
80 efforts. Recently, Imaging Mass Cytometry (IMC) was used to uncover changes in T1D islets,
81 including alterations in β -cell phenotypes, immune composition, vascular density, and basement
82 membrane (Damond et al. 2019; Wang et al. 2019).

83 Despite these advances, our understanding of certain key features of human T1D pathology
84 remains limited. In particular, insulinitis is regulated by checkpoints that ultimately fail in T1D.
85 However, a comprehensive and quantitative search for insulinitis checkpoints has not been
86 performed to date. Furthermore, islets in different regions of the pancreas are infiltrated at
87 strikingly different rates for reasons that are unclear. Several lines of evidence suggest that the
88 non-islet pancreatic tissue could be responsible by governing the targeting of islets: First, peri-
89 insulinitis, which is the accumulation of immune cells outside the islet, is observed in tissues from
90 patients with T1D (Korpos et al. 2013), indicating that not all T cells extravasate directly into islets
91 (Savinov et al. 2003). Second, the composition and functionality of immune and epithelial cells
92 outside islets differ in T1D patients compared to non-diabetic controls (Rodriguez-Calvo et al.
93 2014; Bender et al. 2020; Campbell-Thompson et al. 2012; Campbell-Thompson, Rodriguez-
94 Calvo, and Battaglia 2015; Fasolino et al. 2022). Finally, tertiary lymphoid structures (TLS), which
95 are dense aggregates of lymphoid cells indicative of local immune activation, are observed

96 outside islets in T1D patients (Korpos et al. 2021). To date, multiplexed imaging studies have only
97 examined islets. A comprehensive, spatially resolved cellular analysis of whole pancreatic tissue
98 in T1D is lacking.

99 Here, we investigated both islet and non-islet pancreatic tissue in the progression of T1D. We
100 applied the highly multiplexed tissue imaging platform CO-Detection by indexing (CODEX) with
101 an antibody panel targeting 54 antigens to samples from a cohort of T1D patients with insulinitis
102 as well as non-T1D individuals with and without autoantibodies obtained through the JDRF nPOD
103 program. We analyzed approximately 2000 islets and broad swaths of surrounding tissue to
104 evaluate local and distal spatial architecture. We then used pseudotime analysis to characterize
105 insulinitis sub-states based on the activation states of islet-infiltrating CD8⁺T cells. We further
106 investigated the cellular changes in niches and lobules beyond islets. Our results implicate both
107 the local islet microenvironment and inflammation at distal sites within the pancreas in insulinitis
108 progression, greatly expanding the boundaries of pathologic inflammation in T1D.

109 **Cohort curation, image acquisition, and cell annotation**

110 The JDRF nPOD is a national registry of cadaveric pancreases donated by T1D patients that has
111 transformed the ability to investigate the pathways underlying the development and progression
112 of human T1D (Campbell-Thompson et al. 2012; Pugliese et al. 2014). At the time of our study,
113 17 cases with insulinitis were available from nPOD, from which we selected 10 that had visible
114 insulinitis in preliminary IHC analyses. The final cohort included two autoantibody-positive, pre-
115 T1D cases, eight T1D cases, and three non-diabetic controls. Cases were selected by surveying
116 the nPOD online immunohistochemistry database which contains images of tissue sections triple-
117 stained for Insulin, Glucagon, and CD3. T1D and pre-T1D cases that had CD3⁺ staining in islet or
118 peri-islet spaces and tissue still available were selected for our study. The cases varied in the time
119 between diagnosis and death from 0 years (diagnosed at death) to 6 years (Figure 1.A, left). The
120 causes of death were mostly unrelated to T1D complications (Methods). Therefore, the time
121 since diagnosis is not a reflection of the severity or aggressiveness of the individual's disease.

122 Large regions averaging 55 mm² were imaged with CODEX as previously described (Schürch et al.
123 2020; Phillips, Matusiak, et al. 2021; Hickey et al. 2021). Regions were imaged to capture islets
124 and the surrounding region simultaneously (Figure 1.A, center and right). The algorithm CellSeg
125 was used to segment cell nuclei and quantify marker expression from CODEX images as
126 previously described (Lee et al. 2022). Between 3.0x10⁵ and 9.8x10⁵ cells per donor were
127 obtained resulting in 7.0x10⁶ cells in total. Twenty-one cell types were identified with Leiden
128 clustering and manual merging and visualized using Uniform Manifold Approximation and
129 Projection (UMAP) (Figure 1.B). Endocrine cells were manually gated from UMAP embeddings
130 derived from Proinsulin, Glucagon, and Somatostatin to identify β -cells, α -cells, and δ -cells.
131 Immune cells were sub-clustered with the Leiden algorithm using immune-specific markers
132 (Figure 1.C, Supplemental Table 2). A heatmap of all cell types and their marker expression is
133 displayed in Figure 1.D. Of note, we could not accurately identify macrophage subsets or
134 distinguish dendritic cells from macrophages due to panel design, complex combinations of co-
135 expression, and the difficulty in segmenting and quantifying markers on myeloid populations.
136 Therefore, dendritic cells are contained within the 'macrophage' group for all analyses. In

137 addition, we identified a cell population that could not be definitively annotated, expressing high
138 levels of CD45, CD69, Granzyme-B, and CD44, intermediate levels of CD16, S100A6, Galectin-3,
139 and Hyaluronan, but not expressing lineage markers CD3, CD20, CD56, CD57, CD15, or MPO. We
140 confirmed from the raw images that CD3, CD4, and CD8 were not internalized, indicating
141 activation, nor did these cells express other T cell activation markers CD45RA, CD45RO, PD-1, or
142 LAG-3. This population could represent a type of innate lymphoid cell or mast cells (Dalmás et al.
143 2017; Martino et al. 2015) and was labeled Granzyme-B⁺/CD3⁻ (Figure 1.D).

144 **Islet- and non-islet regions are altered in T1D**

145 We first sought to identify cellular changes in T1D within islets specifically. Previous reports
146 observed that insulin-containing islets are significantly more common in recent-onset T1D cases
147 than cases with diabetes durations of greater than one year (In't Veld 2011). Similarly, we found
148 that samples from patients who had been diagnosed with T1D for 0-2 years had significantly
149 reduced β -cell frequencies compared to non-diabetic controls. Lastly, samples from subjects with
150 disease durations of 5-6 years had minimal remaining β -cell mass (Figure 1.E). Whereas one Pre-
151 T1D case had β -cell mass comparable to those of cases with disease duration of 0-2 years, the
152 other Pre-T1D case was comparable to non-diabetic controls (Figure 1.E).

153 Next, we investigated how the abundances of non-endocrine cell types inside islets differed
154 across donors. We performed Principal Component Analysis (PCA) of the frequencies of non-
155 endocrine cell types located in islets in each donor. Donors were clearly separated into two
156 groups by the first two principal components; one group included all T1D cases and one pre-T1D
157 case and the second group included all non-diabetic cases and the other pre-T1D case (Figure
158 1.F). In this analysis, we did not consider β -cells, α -cells, and δ -cells. Thus, donors were stratified
159 by disease duration strictly according to the abundances of immune and other pancreatic, non-
160 endocrine cell types in the islets.

161 We next considered only cells located outside islets. Again, donors were clearly separable by the
162 first two principal components (Figure 1.G). The first principal component separated cases with
163 times since diagnosis between 0-2 years from non-T1D, pre-T1D, and cases with diabetes
164 durations of 5-6 years (Figure 1.G). The second principal component separated cases with
165 diabetes durations of 5-6 years from the rest (Figure 1.G). Therefore, both the islet and non-islet
166 spaces of T1D and non-T1D cases were distinct.

167 Many cell types were increased in T1D cases with times since diagnosis of 0-2 years relative to
168 non-diabetic controls. In T1D cases with times since diagnosis of 5-6 years, the abundance of
169 different cell types either remained higher than healthy controls or returned to baseline
170 (Supplemental Figure 1). This trend was present in both islet and non-islet regions. These data
171 demonstrate that the immune activity between the islet and extra-islet compartments are
172 coordinated but the cellular programs underlying this crosstalk are unclear.

173 **Pseudotemporal reconstruction of islet pathogenesis** 174 **identifies a conserved trajectory of insulinitis**

175 In human T1D, β -cell destruction does not occur simultaneously in all pancreatic islets in an
176 individual and even neighboring islets can be at different stages of destruction (In't Veld 2011;
177 Damond et al. 2019). We therefore used pseudotime analysis to infer the most likely progression
178 of a single islet through disease space (Damond et al. 2019). To develop a pseudotemporal map
179 of the islets in our study, we quantified the cellular composition of each islet, including cells
180 within 20 μm of the islet's boundary, and applied the pseudotime algorithm PArtition-based
181 Graph Abstraction (PAGA) (Figure 2.A; Figure 2.B), (Wolf et al. 2019). PAGA was selected because
182 it is a high-performing algorithm able to identify multiple trajectories, if they exist, while making
183 minimal assumptions about the true structure (Saelens et al. 2019).

184 Displayed in Figure 2.B is the PAGA force-directed layout where each point represents an islet.
185 Each islet's color corresponds to its pseudotemporal distance from the centroid of non-diabetic
186 islets. As expected, the different donor groups (no T1D, pre-T1D, T1D) had different distributions
187 of islets across the PAGA map (Figure 2.C). In the PAGA map, a continuum is apparent from islets
188 abundant in insulin-expressing β -cells on the left of the map to islets depleted in β -cells on the
189 right of the map (Figure 2.D, Figure 2.E, Figure 2.F, top row). PAGA uses Leiden clustering
190 internally, enabling the following regions of the pseudotime map to be labelled objectively
191 (Supplemental Figure 2.A): 1) Islets with low pseudotime values on the left of the map were
192 labelled 'Healthy' even if they originated from T1D donors. 2) Islets in the middle of the map were
193 elevated in HLA-ABC (MHC Class I) expression, CD8⁺T cells, and macrophages (Figure 2.D, Figure
194 2.E, Figure 2.F, rows 2-4) and were labelled 'Inflamed'. 3) Islets with late pseudotime values on
195 the right of the map were devoid of β -cells and were labelled ' β -Cell Depleted' (Figure 2.D, Figure
196 2.E, Figure 2.F, top row). In addition, islets lacking β -cells occasionally contained CD8⁺T cells and
197 were labelled ' β -Cell Depleted + Immune Islets' (Figure 2.D, Figure 2.E, Figure 2.F, rows 2-4). The
198 presence of these islets suggests that the signals retaining CD8⁺T cells in the islets linger after β -
199 cell death.

200 Islets from non-diabetic controls and one of the pre-T1D donors (6314) were primarily in the
201 Healthy group to the left of the map (Figure 2.C). Islets from subjects who had had T1D for of 5-
202 6 years (cases 6195 and 6323) were primarily in the β -Cell Depleted group to the right of the map
203 (Figure 2.C). All the remaining T1D donors and the other pre-T1D donor were distributed broadly
204 throughout the map (Figure 2.C).

205 Together, these results illustrate a single, non-branching progression from Healthy Islets to β -cell
206 depleted Islets via Inflamed Islets, consistent with previous pseudotime analyses (Damond et al.
207 2019).

208 **IDO expression on islet vasculature is linked to T cell** 209 **infiltration and β -cell death during insulinitis**

210 While inspecting images of islets, we occasionally observed islets with vasculature that stained
211 positive for indoleamine 2, 3-dioxygenase 1 (IDO). In the tumor microenvironment, IDO is
212 expressed by myeloid cells and suppresses CD8⁺T cell activity through multiple mechanisms
213 including induction of FOXP3⁺ regulatory T cells and inhibition of CD8⁺T cell proliferation (Munn
214 and Mellor 2016). In islets, IDO was expressed by CD31⁺ vasculature and not CD45⁺ immune cells
215 adjacent to vasculature (Figure 2.G). IDO was not expressed by other cell types in islets or by
216 vascular cells outside islets (Supplemental Figure 2.B). We manually quantified vascular
217 expression of IDO on islets throughout pseudotime and found that all but two IDO⁺ islets were in
218 the Inflamed group (Figure 2.H). Therefore, IDO expression by islet vasculature was tightly
219 associated with inflammation.

220 We hypothesized that IDO expression was induced by infiltrating immune cells during insulinitis. A
221 major inducer of IDO expression is interferon- γ , a cytokine highly expressed by T cells and
222 macrophages (Munn and Mellor 2016). We compared the frequency of CD8⁺T cells and
223 macrophages in islets from the Inflamed group with and without IDO⁺ vasculature and found that
224 CD8⁺T cells were significantly more abundant in islets with IDO⁺ vasculature than islets without
225 IDO⁺ vasculature (Figure 2.I). The abundance of macrophages was not significantly different in
226 the islets with and without IDO⁺ vasculature (Supplemental Figure 2.C). This implies that during
227 CD8⁺T cell infiltration, IDO is induced on vasculature to subdue the inflammation.

228 Due to IDO's immunosuppressive role in the tumor microenvironment (Munn and Mellor 2016),
229 IDO may protect β -cells from inflammation. If so, for β -cells to be eliminated, IDO-mediated
230 suppression would need to be circumvented through its inhibition or a reduction in IDO's
231 expression. We observed that only 3.3% of islets in the β -Cell Depleted + Immune group had IDO⁺
232 vasculature, whereas 23.9% of islets in the Inflamed group had IDO⁺ vasculature ($p = .017$ chi-
233 square test) (Figure 2.H). This is consistent with the hypothesis that IDO expression is suppressed
234 prior to β -cell loss.

235 In summary, IDO expression by islet vasculature is associated with T cell infiltration and its loss
236 during insulinitis is associated with β -cell depletion. Together, these suggest that IDO⁺ vasculature
237 is an immune regulatory checkpoint that fails in T1D.

238 **Insulinitis has sub-states, defined by functional states of** 239 **CD8⁺T cells**

240 Insulinitis is regulated by checkpoints that fail to control inflammation in T1D. For example, the
241 islet capsule restricts CD8⁺T cells from entering islets (Korpos et al. 2013) and PD-L1 on β -cells
242 suppresses infiltrating CD8⁺T cells (Osum et al. 2018). By definition, a checkpoint prevents an islet
243 from progressing and thus can halt islets in an insulinitis 'sub-state'. Cell differentiation studies
244 have demonstrated the utility of using high-parameter data to infer checkpoints from their
245 corresponding sub-states (Satpathy et al. 2019). We reasoned that we could identify

246 immunoregulatory checkpoints in T1D by identifying sub-states of insulinitis. To identify insulinitis
247 sub-states, we began by characterizing the functional states of CD8⁺T cells in islets. Although,
248 quantifying the expression of functional markers from tissue images can be challenging due to
249 autofluorescence, non-specific antibody staining, and signal spillover between adjacent cells, we
250 overcame these by training a neural network to detect marker expression of single cells from raw
251 cell-images (Figure 3.A, Supplemental Figure 3.A). Using our neural network, we quantified the
252 expression of T cell markers on islet CD8⁺T cells (Figure 3.B).

253 Overall, markers of antigen experience (PD-1, TOX, CD45RO, CD69, CD44) were the most
254 commonly expressed on islet-infiltrating CD8⁺T cells (Supplemental Figure 3.B). CD8⁺T cells
255 expressing CD45RA (which are either naïve or terminally differentiated effector memory cells)
256 were detectable in islets, as previously reported (Damond et al. 2019) (Figure 3.B). PD-1 and TOX
257 were commonly co-expressed on CD45RO⁺ CD8⁺T cells detected in islets (Figure 3.B). We also
258 observed expression of CD69 on CD45RO⁺ CD8⁺T cells, which are likely tissue-resident memory
259 cells (Kuric et al. 2017). CD69 was co-expressed with CD45RA⁺ CD8⁺T cells indicating that naïve T
260 cells are being activated in islets. In addition, we observed a rare population of CD45RO⁺ CD8⁺T
261 cells that co-expressed multiple functional markers including CD69, CD44, LAG-3, Granzyme-B,
262 and ICOS (Figure 3.B bottom clade). Lastly, a rare population of CD57⁺ CD8⁺T cells was present
263 but these cells rarely co-expressed LAG-3, Granzyme-B, or ICOS (Figure 3.B top clade). These
264 populations bear a resemblance to the two exhausted T cell populations identified in the
265 peripheral blood of T1D patients that were associated with responsiveness to alefacept (Diggins
266 et al. 2021). The heterogeneous functional states of CD8⁺T cells in islets demonstrate varying
267 stages of activation, suggesting that they receive additional stimulation after reaching islets.

268 We expected that insulinitis sub-states would be characterized by specific combinations of CD8⁺T
269 cell states found in islets together. To interrogate this, we performed UMAP only on Inflamed
270 islets, using the frequencies of CD8⁺T cells expressing each functional marker. Leiden clustering
271 identified four inflamed sub-clusters, I-IV, (Figure 3.C top). Here, the term “sub-cluster” is used
272 to highlight that these groups were all contained within the previously defined “Inflamed” cluster
273 and the roman numerals are expressly not intended to imply a temporal ordering. Inflamed-I
274 contained only CD8⁺T cells that did not express any of the functional markers analyzed (Figure
275 3.C bottom, top row). Inflamed-II was characterized by a high frequency of CD45RA⁺CD8⁺T cells
276 (Figure 3.C bottom, second row from top and Figure 3.D top row). Inflamed-III was characterized
277 by a low frequency of CD45RA⁺ cells and high frequency of CD45RO⁺ and PD-1⁺ cells that did not
278 co-express any functional markers (Figure 3.C bottom, third row from top and Figure 3.D middle
279 row). Inflamed-IV was characterized by an enrichment of CD8⁺T cells expressing CD57 or LAG-3,
280 ICOS, and Granzyme-B in addition to PD-1 and CD45RO Inflamed-III (Figure 3.C bottom, bottom
281 row and Figure 3.D bottom row). In summary, the diversity of CD8⁺T cells in any particular islet is
282 much more restricted than the diversity of total islet CD8⁺T cell states.

283 The fact that the inflamed sub-clusters are characterized by CD8⁺T cells at different stages of
284 activation suggests that the inflamed sub-clusters represent different stages of a progression
285 rather than distinct trajectories (either within or across patients). In support of this, each
286 individual donor possessed islets that belonged to more than one inflamed islet sub-cluster
287 (Figure 3.E). Therefore, Inflamed-I through Inflamed-IV do not represent patient subtypes but
288 insulinitis sub-states conserved among T1D patients.

289 **Regulation of insulitis sub-states by the islet** 290 **microenvironment**

291 To identify cellular or molecular factors that regulate the state of CD8⁺T cells in islets, we first
292 asked if CD8⁺T cell states are enriched in islets or extend into the peri-islet and exocrine space.
293 To this end, we computed the frequencies of each CD8⁺T cell state inside the islet and in separate
294 swaths of 0-25 μ m, 25-50 μ m and 50-100 μ m away from the islets (Supplemental Figure 3.C). We
295 found that for islets of Inflamed-II, -III, and -IV, functional markers characterizing the CD8⁺T cells
296 were expressed more frequently inside islets than in the surrounding tissue areas. This
297 demonstrated that differences in the compositions of CD8⁺T cell states in different islets were
298 due to the islet microenvironment and not the surrounding exocrine spaces.

299 Although macrophages are abundant in islets from the Inflamed group (Figure 2.E, Figure 2.F) and
300 are capable of interacting with T cells through antigen presentation and cytokine secretion,
301 neither the expression of markers of macrophage activity nor macrophage abundance was
302 significantly associated with islets from inflamed sub-clusters (Supplemental Figure 3.D).
303 Similarly, no other cell-type nor the vascular expression of IDO was linked to CD8⁺T cell programs
304 in islets (Supplemental Figure 3.D). These negative data suggest that transitions between insulitis
305 states are independent of changes in the abundance of any of the cell types identified in our
306 tissues. Consistent with this, the four inflamed sub-clusters had identical distributions
307 throughout the original PAGA force-directed layout (Figure 3.F). These data suggest that insulitis
308 sub-states are transient over the course of insulitis and the CD8⁺T cell states are being regulated
309 by highly dynamic processes.

310 Lastly, β -cells are likely to influence the state of T cells within islets. We reasoned that islets
311 lacking β -cells but containing immune cells could provide information regarding the role of β -
312 cells in regulating the CD8⁺T cell compartment. We therefore examined CD8⁺T cells in islets from
313 the β -cell Depleted + Immune group relative to those in islets from the Inflamed group. We found
314 that TOX was expressed by a higher frequency of CD8⁺T cells in β -Cell Depleted + Immune islets
315 than CD8⁺T cells in Inflamed islets (Figure 3.G), indicating that TOX⁻ CD45RO⁺ T cells are either
316 short lived or exit upon loss of β -cells. In addition, CD45RA was enriched in CD8⁺T cells in β -cell
317 Depleted + Immune islets and that CD45RO was depleted (Figure 3.G). This suggests that
318 CD45RA⁺ CD8⁺T cells convert to CD45RO⁺ in islets and that β -cells are necessary for this process.
319 If this model is correct, CD45RA⁺ CD8⁺T cells in Inflamed islets are specific for islet antigens and
320 are not inert bystanders. Together, these data indicate that islet CD8⁺T cells are stimulated upon
321 entering islets and the factors that regulate this process are highly dynamic (Figure 3.H).

322 **Vasculature, nerves, and Granzyme-B⁺/CD3⁻ cells** 323 **outside islets are associated with the lobular patterning** 324 **of islet pathogenesis**

325 The destruction of islets in T1D is known to exhibit lobular patterning (Gepts 1965). Specifically,
326 islets in the same lobule are likely to be in the same stage of disease. This architecture suggests

327 that the states of islets within the same lobule are coordinated but the cell types responsible are
328 unknown. To systematically investigate lobular patterning in T1D, we used a neural network to
329 segment lobules and assign each single cell to its lobule. We used the intra-class correlation
330 coefficient (ICC) to quantify the variation in islet pseudotime within a lobule relative to variation
331 in islet pseudotime donor wide. ICC ranges from 0 to 1 with cases closer to 1 having a stronger
332 lobular effect on islet pseudotime (Figure 4.A). Islets of non-T1D cases and 6314, 6195, and 6323
333 did not have appreciable variability in their pseudotimes, so the ICC was not applicable, but in
334 the remaining cases, the ICCs ranged from 0.17 to 0.74 (Figure 4.B). This highlights that the
335 magnitude of lobular patterning ranges widely across T1D cases with insulinitis and thus could be
336 influenced by donor characteristics such as the time since diagnosis, etiology or genetics.

337 To identify cell types that coordinate the behavior of islets within lobules, we employed
338 hierarchical linear modeling (HLM), a statistical framework designed to identify relationships
339 between different levels of multi-level data. HLMs are standard in many fields where multi-level
340 data are common (Gelman et al. 2014.) and have been applied in biomedical settings (Jerby-
341 Arnon and Regev 2022; Yi et al. 2019). We were interested in cell-types if their abundance per
342 lobule correlated with the average islet pseudotime per lobule. Importantly, we omitted cells
343 located in islets from the calculation of a cell type's lobular abundance so that information from
344 the pseudotime analysis would not leak into this analysis. For each cell type, we estimated the
345 effect of its total abundance in a lobule (the number of cells divided by the number of acinar cells
346 to normalize for lobule area) on the pseudotimes of islets in that lobule. We performed this
347 analysis in two-level HLMs for each donor and a three-level HLM considering all donors together.

348 We then examined cell types that were significantly associated with lobules across multiple T1D
349 tissue donors. The abundance of three cell types were associated with pseudotime in more than
350 two cases. These were vasculature, Granzyme-B⁺/CD3⁻ cells, and nerves, all of which were more
351 abundant in lobules with islets late in pseudotime (Figure 4.C boxed rows, Figure 4.D). Samples
352 from cases 6323 and 6195 which had very few insulin-containing islets, had increased
353 abundances of vasculature, Granzyme-B/CD3⁻ cells, and nerves (Supplemental Figure 1),
354 indicating these changes persist at least until the entire tissue is afflicted. In addition, vasculature,
355 Granzyme-B⁺/CD3⁻ cells, and nerves were increased in Inflamed islets compared to Healthy islets
356 indicating that they may serve a role in islets in addition to their role in the non-islet compartment
357 (Supplemental Figure 4). It was noteworthy that the conventional pathogenic immune cells
358 comprising insulinitis were not associated with lobular patterning. For example, CD8⁺T cells and
359 macrophages were only significant in one donor, and CD4⁺T cells and B cells were significant in
360 only two donors (Figure 4.C). Therefore, they may depend on detecting signals from vasculature,
361 Granzyme-B⁺/CD3⁻ cells, and nerves in the extra-islet tissue to target a given lobule and the islets
362 therein.

363 **Immature tertiary lymphoid structures far from islets** 364 **are enriched in subjects with T1D**

365 We hypothesized that pancreatic niches may influence the extravasation, migration, or activation
366 of T cells prior to them reaching islets. To characterize pancreatic niches that might influence

367 CD8⁺T cells, we identified Cellular Neighborhoods (CNs) in the pancreas (Schürch et al. 2020;
368 Bhate et al. 2021). CNs are tissue regions that are homogeneous and have defined cell-type
369 compositions. To identify CNs, briefly, single cells were clustered according to the cell-type
370 composition of their twenty nearest spatial neighbors and automatically annotated with the
371 names of enriched cell types (Figure 5.A, See Methods). This resulted in 75 CNs.

372 Next, we identified CNs that were more abundant in T1D than non-T1D tissues (Figure 5.B). The
373 top three CNs (fold change of abundance in T1D relative to abundance in non-T1D) were (CD8⁺T
374 cells|B Cells), (Macrophage|Stromal Cells|B Cells), and (Vasculature|B Cells). All were rich with
375 B cells (Figure 5.B, Figure 5.C). We asked whether these three CNs were commonly adjacent to
376 each other this could indicate that they act as components of a larger structure playing a
377 functional role in the tissue (Bhate et al. 2021). Measuring the adjacency of the three B cell CNs
378 demonstrated that the (CD8⁺T cells|B Cells) CN is predominantly found adjacent to both the
379 other CNs but that (Macrophage|Stroma|B Cells) and (Vasculature|B Cells) are less commonly
380 adjacent to each other (Figure 5.D).

381 We next asked whether these CN assemblies corresponded to either peri-vascular cuffs (Agrawal
382 et al. 2013; Wekerle 2017) or tertiary lymphoid structures (TLSs) (Korpos et al. 2021; Rovituso et
383 al. 2016; Agrawal et al. 2013), as these are two lymphoid-rich structures commonly present in
384 autoimmune conditions. Although the (CD8⁺T cells|B Cells) CN was adjacent to vessels (Figure
385 5.D, Figure 5.E), it was not in the fluid-filled perivascular space, as is the case with perivascular
386 cuffs (Figure 5.E). In our samples, the (CD8⁺T cells|B Cells) CN did not have segregated T cell and
387 B cell zones as seen in mature TLSs, but the size, abundance, and association with vasculature
388 was comparable with those previously described of TLSs in human T1D (Korpos et al. 2021).

389 In summary, the (CD8⁺T cells|B Cells) CN is more abundant in T1D tissues that are undergoing
390 active inflammation than in non-T1D tissues as well as in tissues of patients who had T1D for
391 more than 4 years. Finally, this CN shares many architectural features of immature TLSs.

392 **Immature tertiary lymphoid structures are potential** 393 **staging areas for islet-destined CD8⁺T cells**

394 We next asked whether the (CD8⁺T cells|B Cells) CN had high endothelial venules (HEV),
395 specialized blood vessels that enable naïve lymphocytes to extravasate into peripheral tissues,
396 which are commonly found in TLSs. We observed expression of peripheral lymph node addressin
397 (PNA^d), an HEV marker, in the vessels associated with the (CD8⁺T cells|B Cells) CN (Figure 5.E left
398 image) but not in other vessels (data not shown). Although we could not assess the presence of
399 other TLS traits such as follicular dendritic cells, fibroblastic reticular cells, or follicular helper T
400 cells, the cellular composition and presence of HEVs indicate that instances of the (CD8⁺T cells|B
401 Cells) CN represent immature TLSs.

402 Next, we asked if immature TLSs were supporting the entry of naïve CD8⁺T cells into the pancreas.
403 We observed CD8⁺T cells co-expressing CD45RA and CD62L (the ligand for PNA^d) near PNA^d
404 vasculature (Figure 5.E, middle and right image respectively). Thus, naïve CD8⁺T cells in the
405 pancreas can adhere to HEV receptors. Furthermore, CD45RA⁺ was enriched three-fold on CD8⁺T
406 cells in the (CD8⁺T cells|B Cells) CN relative to CD8⁺T cells in the tissue as a whole (Figure 5.F),

407 providing additional evidence that naïve T cells enter the pancreas through HEVs in the (CD8⁺T
408 cells|B Cells) CN.

409 To determine if immature TLSs delivered naïve lymphocytes directly to islets or acted as
410 “staging areas” by depositing them far from islets, we quantified the frequency of TLSs adjacent
411 to islets. We found that instances of the (CD8⁺T cells|B Cells) CN both adjacent (Figure 5.G.1) or
412 not adjacent (Figure 5.G.2) to islets. Quantifying this adjacency frequency revealed that fewer
413 than half were adjacent to islets (Figure 5.H). We reasoned that even if TLSs were far from
414 islets, extravasating cells may migrate to islets from TLSs. Accordingly, islet-adjacent CD45RA⁺
415 CD8⁺T cells (that were not in islet-adjacent TLSs) co-expressed CD62L, suggesting that they
416 originated from the (CD8⁺T cells|B Cell) CN (Figure 5.I). Consistent with this, in one notable
417 tissue donor, regions of the pancreas with β -cell depleted islets were enriched in the (CD8⁺T
418 cells|B Cell) CN relative to regions of the pancreas with β -cell containing islets (Figure 5.J). This
419 spatial correlation between the (CD8⁺T cells|B Cells) CN and the destruction of islets implicates
420 the CN directly with islet pathology even when it is not adjacent to islets (Figure 5.J). Therefore,
421 our data indicate that immature TLSs act as staging areas by enabling naïve CD8⁺T cells to enter
422 the pancreas far from islets where they then traffic to islets.

423 Discussion

424 We have performed a comprehensive, pseudotemporal analysis of whole pancreatic tissue in T1D
425 using CODEX imaging of cadaveric pancreatic tissues from T1D subjects and computational
426 approaches. Our data support several conclusions.

427 First, a conserved trajectory of insulinitis is present across individual donors and stages of T1D
428 progression. This trajectory is comprised of four sub-states of insulinitis each characterized by
429 CD8⁺T cells at different stages of activation. Moreover, they indicate that T cells receive additional
430 stimulation after entering islets. Multiple inflamed sub-clusters were represented in all T1D
431 donors, indicating that the sub-clusters reflect sub-states capable of inter-converting rather than
432 distinct trajectories of insulinitis that stratify patients.

433 In addition, we observed that IDO⁺ vasculature was present in inflamed islets with higher
434 frequencies of CD8⁺T cells but rare in islets that have lost insulin and contain immune cells,
435 suggesting that IDO is a tolerogenic checkpoint that is lost prior to β -cell death. Leveraging this
436 checkpoint to protect transplanted β -cells from rejection has shown promise (Alexander et al.
437 2002) and could be combined with similar approaches using programmed death-ligand 1
438 (Yoshihara et al. 2020; Castro-Gutierrez et al. 2021).

439 These data support a model wherein all islets in all T1D cases pass through a series of insulinitis
440 substages – perhaps corresponding to immunoregulatory checkpoints - before β -cells are
441 destroyed. This model extends the one previously suggested by Damond et al, who proposed a
442 single trajectory for insulinitis (Damond et al. 2019).

443 Second, pancreatic lobules affected by insulinitis are characterized by distinct tissue markers. We
444 discovered that lobules enriched in β -cell-depleted islets were also enriched in nerves,
445 vasculature, and Granzyme-B⁺/CD3⁻ cells, suggesting these factors may make particular lobules
446 permissive to disease. This could be through recruiting immune cells selectively into islets of

447 particular lobules. Alternatively, the infiltration of a small number of islets in an otherwise
448 unaffected lobule could be a rate-limiting step after which the exocrine space promotes fast
449 dissemination of pathogenic immune cells within the lobule. The role of islet enervation in T1D
450 has been studied but such work has focused on nerves in the islet rather than nerves throughout
451 the lobule (Christoffersson, Ratliff, and von Herrath 2020). It is noteworthy that the cell types
452 linked with direct islet invasion were distinct from those linked to lobule targeting even though
453 both sets of cell types were found across islet and non-islet regions. Therefore, for insulinitis to
454 consume every islet, crosstalk may be required between the cell types of both compartments.
455 Conversely, inhibiting this interaction might contain pathology to isolated lesions.

456 Finally, we identify “staging areas” - immature tertiary lymphoid structures away from islets
457 where CD8⁺T cells assemble, most likely before they navigate to islets Our pseudotime analysis
458 data suggest naïve CD8⁺T cells can enter the pancreas within these “staging areas” before
459 migrating to islets. Similar structures were observed in mice where blocking immune egress from
460 lymph nodes led to a contraction in the size of TLSs and halted diabetes (Penaranda et al. 2010).
461 Thus, therapeutic targeting of immune cell trafficking to TLS could mitigate sustained
462 autoimmunity against β -cells in human T1D.

463 Together, these data implicate both the local islet microenvironment and inflammation at distal
464 sites within the pancreas in insulinitis progression. Our findings expand both the anatomical and
465 cellular scope of autoimmunity in T1D.

466 A major limitation for the study is the cohort size. Cases with documented insulinitis are very rare,
467 significantly limiting the feasibility of curating large cohorts. While we did examine over 2,000
468 individual islets and included both non-diabetic and pre-diabetic controls, larger studies with
469 more diverse patient donor cohorts are needed.

470 Another limitation is our limited perspective on myeloid cell populations. Although antibodies in
471 our panel detect numerous myeloid markers, we failed to identify any heterogeneity in myeloid
472 populations during insulinitis. This was likely due in part to the difficulty of segmenting myeloid
473 cells and quantifying marker expression due to their morphology. Combining spatial or non-
474 spatial transcriptomics could be used in future studies to better define the myeloid populations
475 and extend the CODEX panel.

476 Lastly, our samples are 2-dimensional sections which could affect some of the adjacency
477 relations.

478 In conclusion, using a data-driven approach, we mapped conserved sub-states of insulinitis to infer
479 regulatory checkpoints that fail in T1D and integrated the spatial pathology of islet and non-islet
480 regions into a single model of T1D pathogenesis. The tools and computational pipelines
481 developed here will enable further investigation of immune pathology at the tissue scale that
482 may lead to development of therapies for T1D.

483

484 **Methods**

485 **Human tissues**

486 Cadaveric pancreatic FFPE tissue sections were obtained through the nPOD program, sponsored
487 by the Juvenile Diabetes Research Fund. Case numbers cited herein are assigned by nPOD and
488 comparable across nPOD-supported projects. 17 cases in the nPOD biorepository had been
489 previously documented to possess insulinitis. For each of these 17 cases, we examined the triple
490 stained IHC images (CD3, Insulin, and Glucagon) using nPOD's online pathology database to select
491 blocks in which insulinitis was present. To ensure that the tissue regions still contained insulinitis
492 (and had not been sectioned extensively since their images were uploaded to the nPOD
493 pathology database), we re-sectioned and visualized CD3, Insulin, and Glucagon. We then
494 selected 2 cases at different stages of disease (as defined by time since diabetes diagnosis). 3
495 non-diabetic age matched cases were selected as negative controls. The use of cadaveric human
496 tissue samples is approved by Stanford University's Institutional Review Board.
497

498 **CODEX data collection**

499 *CODEX Antibody Generation and Validation.* Oligonucleotides were conjugated to purified,
500 carrier-free, commercially available antibodies as previously described (Schürch et al. 2020;
501 Kennedy-Darling et al. 2021). For validation experiments, human tonsil and pancreas tissues were
502 co-embedded in a new FFPE blocks so both tissues could be stained and imaged simultaneously.
503 Each antibody in the CODEX panel was validated by co-staining with previously established
504 antibodies targeting positive and negative control cell-types. Once validated, the concentration
505 and imaging exposure time of each antibody were optimized. The tissue staining patterning was
506 compared to the online database, The Human Protein Atlas, and the published literature. The
507 specificity, sensitivity, and reproducibility of CODEX staining has been previously validated
508 (Schürch et al. 2020; Kennedy-Darling et al. 2021; Black et al. 2021; Phillips, Schürch, et al. 2021;
509 Phillips, Matusiak, et al. 2021)
510

511 *CODEX Staining.* Staining and imaging was conducted as previously described (Schürch et al.
512 2020; Kennedy-Darling et al. 2021; Phillips, Schürch, et al. 2021; Black et al. 2021). Briefly, FFPE
513 tissues were deparaffinized and rehydrated. Heat-induced epitope retrieval (HIER) antigen
514 retrieval was conducted in Tris/EDTA buffer at pH9 (Dako) at 97°C for 10 minutes. Tissues were
515 blocked for 1 hour with rat and mouse Ig, salmon-sperm DNA, and a mixture of the non-
516 fluorescent DNA oligo sequences used as CODEX barcodes. Tissues were stained with the
517 antibody cocktail in a sealed humidity chamber overnight at 4°C with shaking. The next day,
518 tissues were washed, fixed with 1.6% paraformaldehyde, 100% methanol, and BS3 (Thermo
519 Fisher Scientific), and mounted to a custom-made acrylic plate attached to the microscope.
520

521 *CODEX Imaging.* Imaging was conducted using the Keyence BZ-X710 fluorescence microscope
522 with a CFI Plan Apo λ 20x/0.75 objective (Nikon). "High resolution" mode was selected in Keyence
523 Navigator software, resulting in a final resolution of .37744 $\mu\text{m}/\text{pixel}$. The exposure times are
524 listed in Supplemental Table 3. Regions for imaging were selected by rendering HLA-ABC,
525 Proinsulin, and CD8 and selecting multiple bounding boxes to maximize the amount of tissue

526 imaged and minimize imaging of empty coverslip. Depending on the tissue shape and islet
527 distribution, each donor was imaged across 2-7 regions ranging from 5x5 to 10x 3mm per region.
528 The full antibody panel and cycle-ordering is detailed in (Supplemental Tables 3 and 4).
529 Biotinylated hyaluronan-binding protein was rendered by adding streptavidin-PE at 1:500
530 concentration to the 96 well plate containing fluorescent oligos in the last cycle and running the
531 CODEX program normally. DRAQ5 was added to the last cycle because we found it stained nuclei
532 more evenly than HOECHST which slightly improved segmentation. Tissues took between 3 and
533 7 days to image depending on the tissue area.

534
535 *Image Pre-processing.* Drift compensation, deconvolution, z-plane selection was performed using
536 the CODEX Toolkit uploader (github.com/nolanlab/CODEX, Goltsev et al. 2018). Cell
537 segmentation using the DRAQ5 nuclear channel and lateral bleed compensation was performed
538 with CellSeg (Lee et al. 2022).

539

540 Cell Type Clustering and Annotation

541 Marker expression was z-normalized within each donor and subsequently clustered in two steps.
542 First, cells were projected into 2 dimensions using the ‘Tissue markers’ indicated in Supplemental
543 Table 2 and Parametric Uniform Manifold Approximation and Projection (pUMAP)(Sainburg,
544 McInnes, and Gentner 2021) was applied on a downsampled dataset. The fit model was used to
545 transform the remaining cells. Cell types were gated using Leiden clustering and manual merging.
546 The cluster containing immune cells was sub-clustered using the ‘Immune Markers’ detailed in
547 Supplemental Table 2. Acinar cells contaminating the Immune cluster were gated out and merged
548 with the Acinar cluster from the previous step. The Endocrine class was sub-clustered into α -, β -
549 , and δ -Cells using Glucagon, Proinsulin, and Somatostatin respectively. Clusters were annotated
550 according the heatmap marker expression.

551

552 Islet Segmentation and Pseudotime

553 *Preprocessing.* Windows consisting of the twenty nearest spatial neighbors surrounding each
554 single cell were clustered according to their cell-type composition using Mini Batch K Means with
555 $k=200$. For this analysis, α -, β -, and δ -Cells were combined into one ‘Endocrine’ cell type. One
556 cluster was highly enriched in Endocrine cells and accurately defined the islet area. Individual
557 islets were identified using the connected components algorithm and filtering out islets that had
558 fewer than ten total cells. For each islet, the number of each cell type inside the islet and between
559 the islet edge and 20 μ m beyond were extracted. To adjust for variation due to the islet size, the
560 cell type counts were divided by the number of endocrine cells inside the islet. Data were then
561 log-transformed.

562

563 *PAGA Analysis.* The PAGA embedding was computed using the default parameters except for the
564 following: The neighborhood search was performed using cosine distance and 15 nearest
565 neighbors; Leiden clustering used a resolution of 1. For computing the pseudotime values (used
566 in the colormap in Figure 2B, the x-axis in Figure 2F, and Figure 4), the path through the inflamed
567 islet was isolated by temporarily omitting 25 islets positioned in the middle of the map between
568 Healthy and β -cell depleted islets. Only 9 of these were from T1D or pre-T1D donors.

569

570 Quantification and Validation of Functional Marker Gating

571 *Annotation of Ground-Truth Dataset.* 3963 CD8⁺T cells were labelled for fifteen markers by an
572 immunologist familiar with the staining patterns of each marker using VGG Image annotator
573 (Abhishek Dutta and Andrew Zisserman 2019).

574

575 *Automated Thresholding.* For each functional marker of interest, the lateral-bleed-compensated
576 mean fluorescence (Lee et al. 2022) of background cells were used to calculate a background
577 distribution. Background cells were cells except those assigned to cell types that were known to
578 express the markers of interest or autofluorescence. Marker-positive cells were defined as those
579 whose expression was greater than the 99th percentile of the background distribution.

580

581 *Gating with Neural Network:* Cell images were split into training, validation, and test splits (60/
582 15/25). The ResNet50 architecture and initial weights were imported from the Keras library pre
583 trained on ImageNet. Image augmentation consisted of random flips, rotations, zooms, contrast,
584 and translation (+/- ten pixels only). All weights were unfrozen, and the model was trained for
585 100 epochs (see attached source code for training details).

586

587 Sub-clustering of Inflamed Islets with Cell-Type specific Functional

588 Markers

589 For each Inflamed Islet (n=351), the frequency of each marker expressed by CD8⁺T cells was
590 computed. Single cells inside the islet and within 20 μ m from the islet's edge were combined
591 before the frequency was measured. The subsequent matrix underwent z-normalization
592 followed by UMAP and clustering using Bokeh. β -Cell Depleted + Immune Islets were defined as
593 islets without β -cells with greater than two CD8⁺T cells and greater than seven macrophages.
594 These thresholds correspond to the 95th percentiles of CD8⁺T cells and macrophages in Healthy
595 islets.

596

597 Identification of Cellular Neighborhoods

598 Previously, CNs (Schürch et al. 2020) were identified by, for each single cell, defining its 'window'
599 as the 20 spatial nearest neighbors. Cells were clustered according to the number of each cell
600 type in their windows using Mini Batch K-Means. The output clusters corresponded to CNs. To
601 ensure our method was sensitive to rare neighborhoods, we adapted this algorithm by
602 intentionally over-clustering, using k=200 in the K- Means step rather than using a k ranging from
603 10-20 as used elsewhere (Bhate et al. 2021; Phillips, Matusiak, et al. 2021; Shekarian et al. 2022).
604 Next, to determine which cell types were characteristic of each cluster, we identified, for each
605 cluster, the set of cell-types that were present in more than 80% of the windows allocated to that
606 cluster. We named the clusters according to this set of cell-types and merged all clusters with the
607 same name, resulting in seventy-five CNs. Acinar cells and epithelial cells were used in the kNN
608 graph and in the clustering but were not considered when merging clusters. Note that this
609 method does not differentiate neighborhoods that have the same combination of cell types but
610 different stoichiometries.

611 Lobule Segmentation

612 A training dataset was generated by manually tracing the edges of lobules in ImageJ using the
613 ROI function. The ROI were then floodfilled in Python and used as masks for training. For each
614 tile, the blank cycle was selected to distinguish tissue from background coverslip. A U-Net
615 model was trained for 10 epochs (see attached source code for training details). After stitching
616 together all masks, the resulting images required slight refinement where lobules were not
617 completely separated, and this was done manually in ImageJ. The connected components in the
618 stitched image defined the lobule instances. Cells were assigned to a lobule by indexing the
619 lobule mask with their X and Y coordinates. Cells in the inter-lobular space were assigned to
620 one “edge” lobule. This resulted in 464 lobules.

621

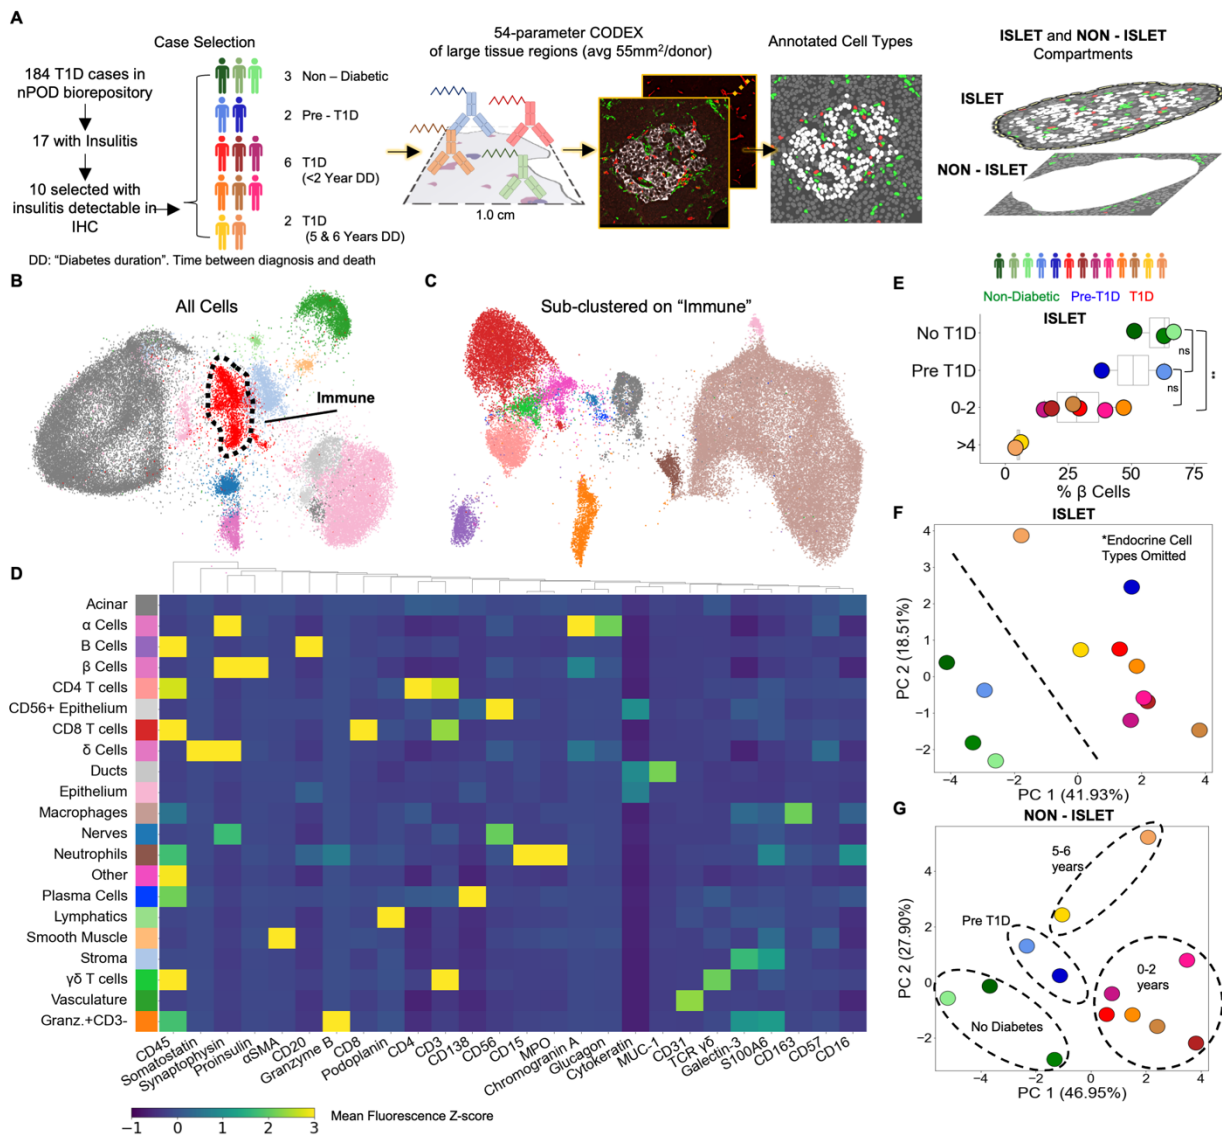

622 Formulation of Hierarchical Linear Models

623 For each lobule, the number of each cell type in non-islet cells was divided by the number of
624 acinar cells in the lobule. For all HLMs, the lme4 package for R was used (Bates et al. 2015) and
625 statistical significance was computed using the lmerTest package for R (Kuznetsova, Brockhoff,
626 and Christensen 2017). Lobular cell-type abundance was z-normalized within each donor and
627 the pseudotime was z-normalized across the entire dataset prior to fitting. For each cell type, a
628 two-level, random intercept HLM within each donor was constructed with the following
629 formulation (in R formula syntax): $pseudotime_{islet} \sim celltype_{lobule} + (1|lobuleID)$ and a three-level
630 random intercept, random slope HLM including islets from all donors was formulated:
631 $pseudotime_{islet} \sim celltype_{lobule} + (1 + celltype_{lobule} | donorID) + (1|lobuleID)$. Here, $pseudotime_{islet}$
632 equals the pseudotime of each islet, $celltype_{lobule}$ equals the number of the given cell type in a
633 particular lobule divided by the number of acinar cells in that lobule, z-normalized within each
634 donor, and $lobuleID$ and $donorID$ are categorical variables specifying the lobule and donor that
635 the given islet belongs to.

636

637 Neighborhood Adjacency

638 The adjacency between neighborhoods was computed as in (Bhate et al. 2021). The only
639 modification was that neighborhood instances were identified using connected components of
640 the k-NN graph with k=5 rather than from the thresholded images.

641
642 **Figure 1 Profiling of T1D pancreata with CODEX high-parameter imaging reveals**
643 **alterations in islet and non-islet regions.**

644 Figure 1.A Left: Schematic of the workflow for selection of nPOD cases. Blues, greens, and reds
645 indicate non-diabetic, pre-T1D, or T1D status, respectively. Center: Schematic for acquisition and
646 processing of CODEX highly multiplexed imaging dataset. Right: Schematic of islet and non-islet
647 pancreatic regions.

648 Figure 1.B UMAP and Leiden clustering of major cell types. Colors match those in heatmap shown
649 in Figure 1D, except for the immune cluster, which is shown in red.

650 Figure 1.C UMAP of immune cluster further clustered from the immune population identified in
651 Figure 1B. Colors match those in heatmap shown in Figure 1D.

652 Figure 1.D Heatmap of mean z-normalized marker expression in each cell-type cluster (color-
653 coded on the left). Only a subset of the markers used for the UMAP are included in the heatmap
654 to facilitate visualization. A full description of the markers used for the clustering stages is
655 available in Supplemental Table 2.

656 Figure 1.E Frequency of β -Cells per donor determined by dividing the number of β -cells by the
657 total number of β -cells, α -cells, and δ -Cells. Blues, greens, and reds indicate non-diabetic, pre-
658 T1D, or T1D status, respectively. Significance was determined using the t-test (* $p < 0.05$, **
659 $p < 0.01$, *** $p < 0.001$)

660 Figure 1.F Principal component analysis of islet compartment. The number of cells of each cell
661 type (omitting α -, β -, and δ -cells) were divided by the number of endocrine cells to adjust for
662 different islet areas. Blues, greens, and reds indicate non-diabetic, pre-T1D, or T1D status,
663 respectively.

664 Figure 1.G Principal component analysis of non-islet compartment. The number of cells of each
665 cell type (omitting α -, β -, and δ -cells) were divided by the number of acinar cells to adjust for
666 different areas imaged. Blues, greens, and reds indicate non-diabetic, pre-T1D, or T1D status,
667 respectively.

668

669
670

671 **Figure 2 Pseudotemporal reconstruction of insulinitis identifies IDO on islet vasculature as a**
672 **regulatory checkpoint.**

673 Figure 2.A Schematic of islet segmentation and quantification of islet cellular composition.

674 Figure 2.B PAGA-force directed layout of islets colored by pseudotime. The start point of
675 pseudotime was calculated as the centroid of the non-diabetic islets. Representative islets from
676 different stages of pseudotime are indicated with black points and their raw images are depicted
677 in Figure 2.D Healthy, Inflamed, and β-Cell Depleted were identified by examining the cell
678 composition of the clusters obtained internally by the PAGA algorithm (Supplemental Figure 2.A).

679 Figure 2.C Islet distribution across pseudotime for each donor. The titles indicate nPOD case IDs
680 as in Supplemental Table 1.

681 Figure 2.D Images of Proinsulin, HLA-ABC, CD163, and CD8 staining in islets representative of
682 different points along pseudotime as indicated in B. Scale bars (lower left of each column)
683 indicate 100 μ m.

684 Figure 2.E Quantification of selected features across pseudotime overlaid onto the PAGA force-
685 directed layout. For β -cells, macrophages, and CD8⁺T cells, the values correspond to log(# cells/#
686 endocrine cells). For HLA-ABC, the mean HLA-ABC expression for each cell in the islet was
687 computed and log transformed.

688 Figure 2.F Quantification of selected features across pseudotime. For β -cells, macrophages, and
689 CD8⁺T cells, the values correspond to log(# cells/# endocrine cells). For HLA-ABC, the mean HLA-
690 ABC expression for each cell in the islet was computed and log transformed. Color legend:
691 Healthy islets: pink; Inflamed islets: brown; β -Cell Depleted islets: purple. Black points demarcate
692 LOWESS regression.

693 Figure 2.G Representative image of an islet from the Inflamed group stained with IDO and, from
694 left to right, Synaptophysin, CD31, and CD45. Arrows indicate IDO⁺/CD31⁺ vasculature. Right
695 shows that IDO⁺ cells are negative for CD45 and therefore, are not myeloid cells associated with
696 vasculature. Scale bar (bottom left image) indicates 50 μ m.

697 Figure 2.H Distribution of IDO expression on islet vasculature across pseudotime.

698 Figure 2.I Association of IDO⁺ islet vasculature with islet CD8⁺T cell density. The y-axis corresponds
699 to the number of CD8⁺T cells per endocrine cell per islet. CD8⁺T cell counts were normalized to
700 adjust for islet size. The x-axis indicates islets whether islets contain IDO⁺ vasculature. Each color
701 corresponds to a donor. All donors with detectable IDO⁺ Islet vasculature are displayed which
702 consisted of 6480, 6267, 6520, 6228, and 6362. Colors are same as in Figure 2.C. IDO⁺ vasculature
703 was manually quantified. For combined donors, significance was determined with a mixed-effect
704 linear model, $p = 1.5 \times 10^{-12}$ (Satterthwaites's method lmerTest R package).

705

706

707 **Figure 3 Insulitis has sub-states, characterized by CD8⁺T cell functionality**

708 Figure 3.A Schematic of marker-quantification with a ResNet50 neural network. Raw images are
 709 input, and the neural network outputs a number between 0 and 1 indicative of the level of
 710 confidence that the cell expresses that marker with 1 indicating the highest confidence.

711 Figure 3.B Heatmap of all 2,855 Inflamed Islet CD8⁺T cells, hierarchically clustered according to
 712 marker expression predicted by the neural network.

713 Figure 3.C Top) UMAP of Inflamed Islets based on frequencies of markers on CD8⁺T cells in islets.
 714 Bottom) Mean frequencies of each marker on CD8⁺T cells in islets of each inflamed sub-cluster.

715 Figure 3.D Representative images of islets from each subcluster with associated immune markers.
 716 Scale bars indicate 50 μm.

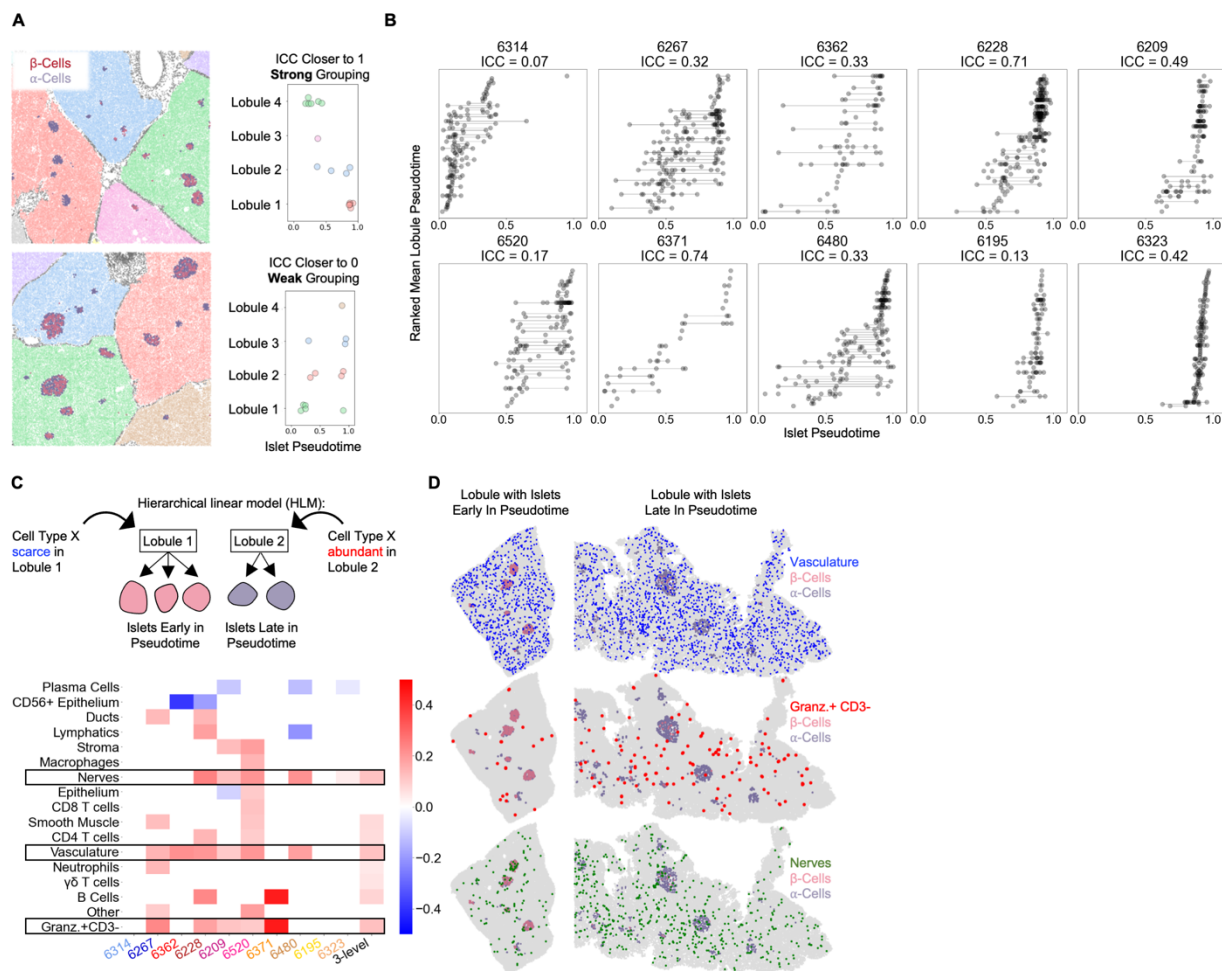

717 Figure 3.E Frequencies of islets from each subcluster per donor in pre-T1D and T1D samples. Color
 718 indicates subcluster as in panel C.

719 Figure 3.F Distribution of the islets of Inflamed-I through -IV on the PAGA force-directed layout
 720 shown in Figure 2.B

721 Figure 3.G Differences in marker expression frequencies between CD8⁺T cells in islets from the
 722 Inflamed group and from the β-Cell Depleted + Immune group. T cells from all islets of the

723 specified groups were pooled within each donor to compute the frequencies of marker
 724 expression. Significance was determined using the Wilcoxon signed-rank test (* $p < 0.05$, **
 725 $p < 0.01$, *** $p < 0.001$) and was not corrected for multiple hypothesis testing.

726 Figure 3.H Proposed model of coordinated T cell states in islets due to stimulation and re-
 727 stimulation of CD8⁺T cells in islets.

728

729 **Figure 4 Vasculature, nerves, and Granzyme-B⁺/CD3⁻ cells outside islets are associated with**
 730 **the lobular patterning of islet pathogenesis**
 731 Figure 4.A A schematic of the method for quantifying lobular patterning of insulinitis. Lobules were
 732 segmented and individual islets were mapped back to the lobules where they were found. Top:
 733 An example region with a strong lobular grouping effect and an ICC closer to 1. Bottom: An
 734 example region with a weak lobular grouping effect and an ICC closer to 0.

735 Figure 4.B Islet pseudotimes in each nPOD donor with pre-T1D or T1D grouped by lobule. Each
 736 point represents an islet. The x-axis represents the islet pseudotime. The y-axis represents each
 737 lobule ranked by the mean pseudotime of islets in that lobule. Violin plots per lobule are overlaid.
 738 Abbreviations: ICC: Intraclass correlation coefficient.

739 Figure 4.C Cell types associated with lobular patterning. Top: Schematic of the hierarchical linear
 740 model. Cells in islets were omitted when computing the lobular abundance of each cell-type.
 741 Bottom: Coefficients of two-level models trained on each donor separately (columns labeled by
 742 donor) and a three-level model (right column). Color corresponds to the coefficient and features
 743 with $p > 0.05$ are white. Significance was determined using Satterthwaites's method in the
 744 lmerTest R package. No adjustment for multiple hypothesis testing was applied.

745 Figure 4.D Visualization of vasculature (top), Granzyme-B/CD3- cells (middle), and nerves
 746 (bottom) in two lobules. The left lobule represents lobules with islets earlier in pseudotime and
 747 a lower abundance of the given cell type in the lobule. The right lobule represents lobules with
 748 islets late in pseudotime and a greater abundance of the given cell type in the lobule.

749

750 **Figure 5 Immature tertiary lymphoid structures far from islets are potential staging areas for**
751 **islet-destined CD8⁺T cells**

752 Figure 5.A Schematic of algorithm for identifying CNs. Red point indicates index cell for the CN.
753 Orange points indicate the nearest neighbors of the index cell. Windows are collected for each
754 cell in the dataset (indicated by orange arrows).

755 Figure 5.B Cell-type compositions of the top CNs organized in decreasing order of the fold
756 increase in abundance in T1D vs. non-T1D samples. Each column in the heatmap indicates the
757 mean density of that cell type in the 20 nearest spatial neighbors of cells assigned to the CN
758 designated for that row. Abundance was calculated as the number of cells assigned to the given
759 CN divided by the number of acinar cells. Abbreviations: Vasc.: vasculature; Mac.: macrophages;
760 Lym.: lymphatics. Neu.: neutrophils; CD8 T: CD8⁺T cells; CD4 T: CD4⁺T cells. Endocrine cell types
761 were merged during CN annotation and are labeled “Islet”.

762 Figure 5.C Mean abundances of the CD8⁺T cell and B cell CNs per donor. Abundance was
763 calculated as the number of cells assigned to the given CN divided by the number of acinar cells.
764 Significance was determined using the Mann-Whitney U test (* p<0.05, ** p<0.01, *** p<0.001).
765 No adjustment for multiple hypothesis testing was applied.

766 Figure 5.D Top: Adjacency frequencies of (CD8⁺T cells| B Cell CN) with (Macrophage|Stroma|B
767 Cells) and (Vasculature| B Cells) CNs. The adjacency frequency was calculated as the number of
768 instances of the source CN adjacent to the destination CN divided by the total number of
769 instances of the source CN. Bottom Left: Raw image of a representative assembly of the three
770 CNs (CD8⁺T cells| B Cell CN), (Macrophage|Stroma|B Cells), and (Vasculature| B Cells) displaying
771 CD8 and CD20 staining. Bottom Right: The same assembly as to the left colored by CN. Scale bar
772 indicates 50µm).

773 Figure 5.E Representative images of co-localization of PNA⁺ endothelium and CD45RA⁺ CD62L⁺
774 CD8⁺T cells located in the (CD8⁺T cells| B Cells) CN. Scale bar indicates 50µm.

775 Figure 5.F Enrichment of CD45RA expression on CD8⁺T cells located in (CD8⁺T cell | B cell) CN
776 relative to CD8⁺T cells throughout the tissue. Significance was determined with a Wilcoxon
777 signed-rank test (* p<0.05, ** p<0.01, *** p<0.001).

778 Figure 5.G Representative images in case 6209 of (CD8⁺T cells| B Cells) instances adjacent to islets
779 (G.1) and not adjacent to islets (G.2). Scale bars indicate 200µm.

780 Figure 5.H Quantification of the adjacency frequencies between the (CD8⁺T cells| B Cells) CN and
781 CNs rich in endocrine cells (i.e “Islet CNs”). Mean, std: mean and standard deviation adjacency
782 frequency across T1D donors. Abbreviations: Vasc.: vasculature; Mac.: macrophage.

783 Figure 5.I Representative images in case 6209 of islet-associated CD45RA⁺ CD62L⁺ CD8⁺T cells.
784 Scale bar indicates 50 µm.

785 Figure 5.J Image in case 6209 showing the spatial distribution of the (CD8⁺T cells| B cells) CN
786 instances relative to islets and the enrichment of (CD8⁺T cells| B cells) CN instances in areas of
787 the pancreas with islets lacking β-Cells.

788 Figure 5.K Proposed model of coordinated T cell stimulation in islets in T1D rejuvenated by naïve
789 T cells that enter the pancreas at the (CD8⁺T cells|B Cells) CN outside islets.

790

791

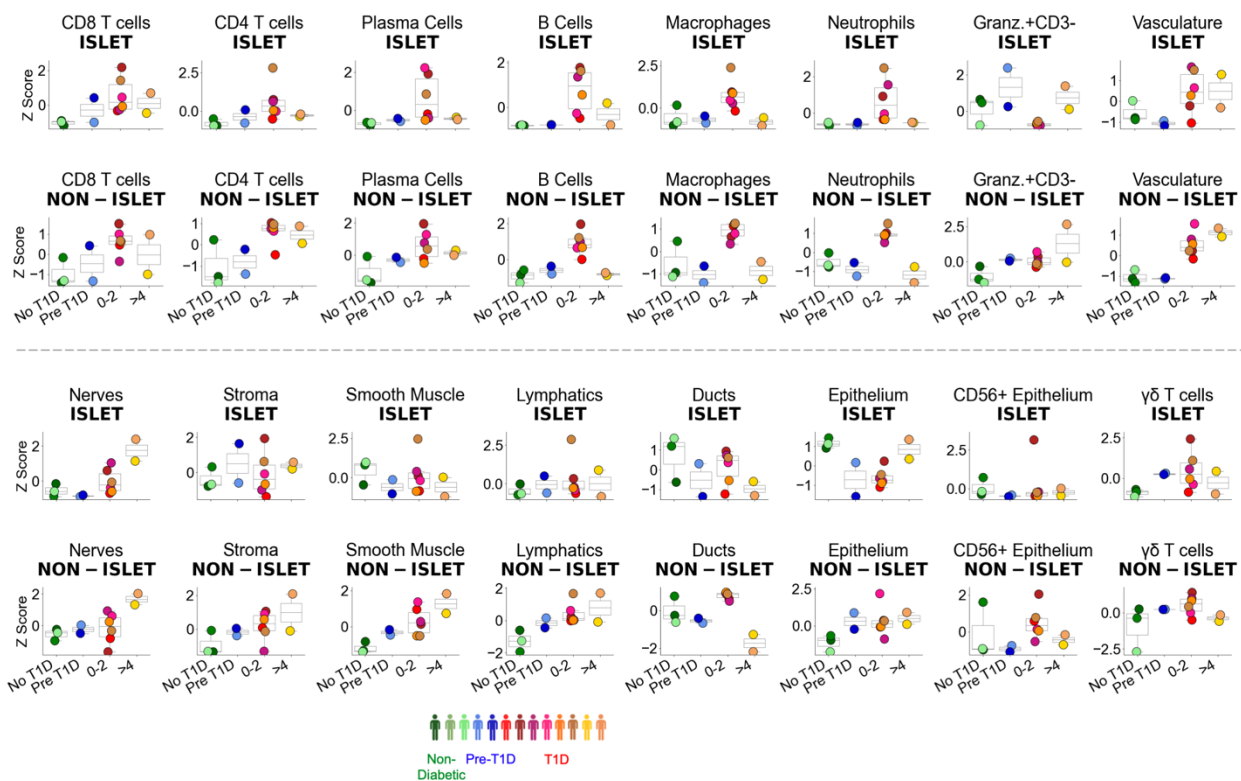

792

793

794

1 Supplemental Information

2

3

4 Supplemental Figure 1 Related to Figure 1.

5 Supplemental Figure 1.A Changes in cellular abundance in Islet (top) and non-islet (bottom)
6 regions. The Y-axis corresponds to the number of the given cell type / number of endocrine
7 cells in the top row and the number of a given cell type / number of acinar cells in the bottom
8 row in each donor. These frequencies were then z-normalized across donors.

9

10

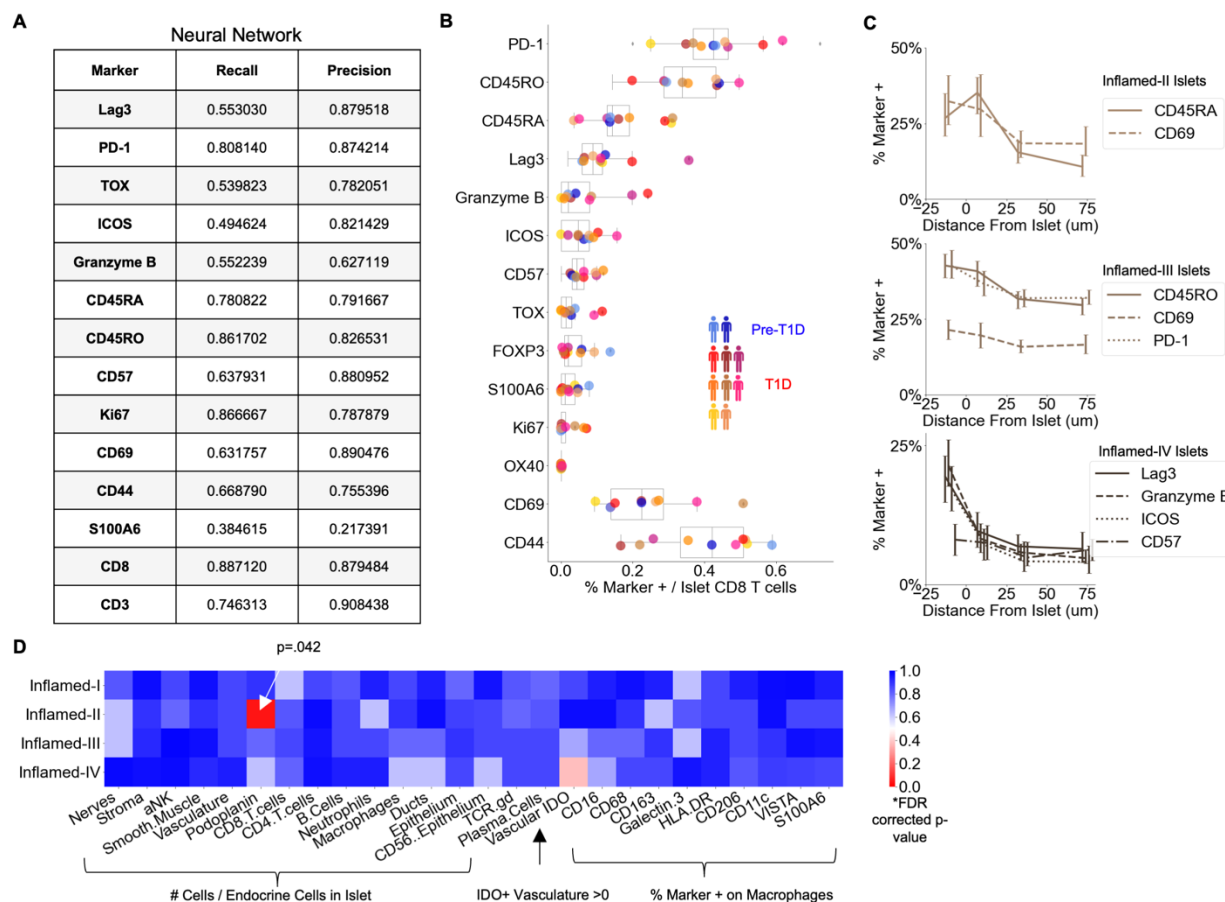

11 Supplemental Figure 2 Related to Figure 2.

12 Supplemental Figure 2.A Leiden clustering computed by PAGA algorithm internally. Clusters 0
13 and 5 were assigned to the 'Healthy' group. Clusters 6, 2, and 8 were assigned to the "Inflamed"
14 group. Clusters 1,3,7, and 4 were assigned to the "β-Cell Depleted" group.

15 Supplemental Figure 2.B Frequency of IDO on vasculature at different distances from islets.
 16 Dashed line indicates the frequency in and around islets where IDO⁺ was detected in islet
 17 vasculature (n=84) as in Figure 2.H. Solid line indicates the frequency in and around Inflamed
 18 Islets in which IDO was absent (n=267). Error bars indicate 95% confidence intervals obtained
 19 by iteratively calculating the marker frequency in re-sampled islets with replacement (n=200)

20 Supplemental Figure 2.C Macrophage abundance in IDO⁺ and IDO⁻ islets. Same as Figure 2.I.
 21 Asterisks in figure indicate significance within each donor. For combined donors, significance
 22 was determined with a mixed-effect linear model, p = 0.72 (Satterthwaites's method lmerTest R
 23 package).

24

25

26 **Supplemental Figure 3 Related to Figure 3**

27 Supplemental Figure 3.A Validation of neural network for detecting expression of weak
 28 antigens. Left: Recall and Precision for the automated gating scheme (see Methods). Right:
 29 Recall and Precision for the neural network. Both tables were computed using cells in the "Test"
 30 dataset unseen by the neural network.

31 Supplemental Figure 3.B Frequency of functional markers on CD8⁺T cells inside islets. Colors
 32 correspond to donor. Only Pre-T1D and T1D donors are displayed.

33 Supplemental Figure 3.C Frequency of functional markers on CD8⁺T cells at different distances
 34 from islets. Error bars indicate 95% confidence intervals obtained by iteratively calculating the
 35 marker frequency in re-sampled islets with replacement (n=200).

36 Supplemental Figure 3.D Association of islet features with Inflamed-I through -IV. For each
 37 feature (columns), a mixed-level model adjusting for donor was fit in a one-vs-all design and the
 38 p-value was determined using Satterthwaites's method in lmerTest R package. Values in the
 39 heatmap were corrected for multiple hypotheses using the Benjamini, Hochberg method.

40

41 **Supplemental Figure 4 Related to Figure 4**

42 Supplemental Figure 4.A Changes in cell types identified by HLM in insulitis. Each point
 43 represents an islet. Islets are grouped according to the pseudotime analysis from Figure 2. The
 44 y-axis corresponds to the log-transformed values for the number of the given cell type /
 45 number of endocrine cells. Significance was determined using the t-test (* p<0.05, ** p<0.01,
 46 *** p<0.001). No adjustment for multiple hypothesis testing was applied.

52
53 **Supplemental Table 2: Markers used for cell-type identification.** Channels in the "Both" column
54 were used for clustering all cells and specifying immune cells. Channels in the "All" column were
55 only used for clustering all cells and the UMAP in Figure 1.B. Channels in "Immune" columns were
56 only used for sub-clustering immune cells and the UMAP in Figure 1.C. Channels in "Endocrine"
57 column were used for sub-clustering endocrine populations. Channels in "Un-used" column were
58 not included in the clustering or UMAP step because they were either too weak to aid clustering
59 or were expressed on multiple cell-populations and confounded cell-type identification.

1024 **Acknowledgements**

1025 This research was performed with the support of the Network for Pancreatic Organ donors with
1026 Diabetes (nPOD; RRID:SCR_014641), a collaborative type 1 diabetes research project supported
1027 by JDRF (nPOD: 5-SRA-2018-557-Q-R) and The Leona M. & Harry B. Helmsley Charitable Trust
1028 (Grant#2018PG-T1D053, G-2108-04793). The content and views expressed are the responsibility
1029 of the authors and do not necessarily reflect the official view of nPOD. Organ Procurement
1030 Organizations (OPO) partnering with nPOD to provide research resources are listed
1031 at <http://www.jdrfnpod.org/for-partners/npod-partners/>. Research reported in this publication
1032 was supported by the National Cancer Institute and National Institute of Allergy and Infectious
1033 Diseases of the National Institutes of Health under Award Numbers K99CA246061,
1034 5U54CA209971-05, 5U2CCA233195-02, 1U2CCA233238-01, 5U2CCA233195-02, 5U01AI101984-09. The
1035 content is solely the responsibility of the authors and does not necessarily represent the official
1036 views of the National Institutes of Health. C.M.S. was supported by the Swiss National Science
1037 Foundation (P300PB_171189, P400PM_183915). We like to thank Yury Goltsev, Pauline Chu,
1038 Sarah Black, Gustavo Vazquez, Aviv Hargil (Stanford University), and Irina Kusmartseva (nPOD)
1039 for excellent assistance. We like to thank Dr. Xavier Rovira-Clavé (Stanford University) for critical
1040 comments on the manuscript.

1041 **Author information**

1042 G.L.B curated data, wrote software, and analyzed data. D.P. and C.M.S contributed significantly
1043 to validating the antibody panel and assisted with analysis. S.D., S.S.B, A.Y., H.A.M., G.K.K., N.N.,
1044 S.R., and J.M. assisted with analysis. G.L.B., J.A.B., G.P.N., and P.L.B., conceptualized the study
1045 and wrote the manuscript. All authors have read and approved the final version of the
1046 manuscript.

1047 **Ethics declarations**

1048 P.L.B.: Founder, Halo Biosciences.

1049 N.N.: Founder, Halo Biosciences.

1050 PLB, NN and GK have filed intellectual property around 4-MU. PLB, NN and GK hold a financial
1051 interest in Halo Biosciences, a company that is developing 4-MU for various indications.

1052 G.P.N. has received research grants from Vaxart and Celgene during the course of this work and
1053 has equity in and is a scientific advisory board member of Akoya Biosciences. Akoya Biosciences
1054 makes reagents and instruments that are dependent on licenses from Stanford University.
1055 Stanford University has been granted US patent 9909167, which covers some aspects of the
1056 technology described in this paper.

1057 J.A.B.: Board of director for Gilead and CEO and President of Sonoma Biotherapeutics; scientific
1058 advisory boards of Arcus Biotherapeutics and Cimeio Therapeutics; consultant for Rheos
1059 Medicines, Provention Bio; stockholder in Rheos Medicines, Vir Therapeutics, Arcus
1060 Biotherapeutics, Solid Biosciences, Celsius Therapeutics; Gilead Sciences, Provention Bio,
1061 Sonoma Biotherapeutics.

1062 C.M.S.: Scientific advisory board of, stock options in, research funding from Enable Medicine, Inc.
