17 **Abstract**

18 Background: Over 1.3 billion people, or 16% of the world's population, live with some
19 form of disability. Recent studies have reported that people with disabilities (PwD)
20 might not be receiving state-of-the-art treatment for cancer as their non-disabled
21 peers; our objective was to systematically review this topic.

22 Methods: A systematic review was undertaken to compare cancer outcomes and
23 quality of cancer care between adults with and without disabilities (NIHR Prospero
24 register ID number: CRD42022281506). A search of the literature was performed in
25 July 2022 across five databases: EMBASE, Medline, Cochrane Library, Web of
26 Science and CINAHL databases. Peer-reviewed quantitative research articles,
27 published in English from 2000 to 2022, with interventional or observational study
28 designs, comparing cancer outcomes between a sample of adult patients with
29 disabilities and a sample without disabilities were included. Studies focused on
30 cancer screening and not treatment were excluded, as well as editorials,
31 commentaries, opinion papers, reviews, case reports, case series under 10 patients
32 and conference abstracts. Studies were evaluated by one reviewer for risk of bias
33 based on a set of criteria according to the SIGN 50 guidelines. A narrative synthesis
34 was conducted according to the Cochrane SWiM guidelines, with tables
35 summarizing study characteristics and outcomes. This research received no external
36 funding.

37 Results: Thirty-one studies were included in the systematic review. Compared to
38 people without disabilities, PwD had worse cancer outcomes, in terms of poorer
39 survival and higher overall and cancer-specific mortality. There was also evidence
40 that PwD received poorer quality cancer care, including: lower access to state-of-the-

41 art care or curative-intent therapies, treatment delays, undertreatment or excessively
42 invasive treatment, worse access to in-hospital services, less specialist healthcare
43 utilization, less access to pain medications and inadequate end-of-life quality of care.

44 Discussion: Limitations of this work include the exclusion of qualitative research, no
45 assessment of publication bias, selection performed by only one reviewer, results
46 from high-income countries only, no meta-analysis and a high risk of bias in 15% of
47 included studies. In spite of these limitations, our results show that PwD often
48 experience severe disparities in cancer care with less guideline-consistent care and
49 higher mortality than people without disabilities. These findings raise urgent
50 questions about how to ensure equitable care for PwD; in order to prevent avoidable
51 morbidity and mortality, cancer care programs need to be evaluated and urgently
52 improved, with specific training of clinical staff, more disability inclusive research,
53 better communication and shared decision-making with patients and elimination of
54 physical, social and cultural barriers.

55

56

57 Introduction

58 Cancer is a leading cause of death worldwide, resulting in nearly ten million deaths
59 in 2020 according to WHO data.(1) In spite of this enormous burden of disease, late-
60 stage presentation and lack of diagnosis and treatment remain common, leading to
61 much higher mortality rates.(2) Each cancer type requires a different treatment
62 regimen, so a correct diagnosis is essential to receiving the best treatment and
63 reducing mortality.(1-3)(1) Good quality of care can also improve quality of life (e.g.
64 through pain management), even when cure is no longer possible. Access to
65 appropriate treatment is therefore of crucial importance, but inequalities in access
66 have been observed for several groups, including PwD.(4–10)
67 Over 1.3 billion people, or 16% of the world's population, live with some form of
68 disability, according to the 2022 World Report on Disability. (11) This figure is
69 expected to grow further in the coming decades, as the population ages and chronic
70 health conditions increase globally. On average, PwD are more likely to experience
71 poor health, because of their underlying health condition/impairment and their socio-
72 economically excluded position in society. (14-15) They also face a range of barriers
73 to accessing care, including long waiting times, high costs, ableist discrimination by
74 health professionals, inaccessible buildings, inconvenient locations, and lack of
75 communication among different parts of the healthcare team. (12) As a
76 consequence, unmet healthcare needs are greater for PwD, contributing towards
77 poorer health and higher mortality. (11) This general pattern of disability-related
78 healthcare exclusion is reflected in known disparities in the use of cancer prevention
79 services, as PwD have lower cancer screening rates than those without disabilities.
80 (13–18) This gap may also exist with respect to cancer care, as several studies have

81 recently reported that patients with disabilities might not be receiving state-of-the-art
82 treatment standards for their cancers. (19–23) Furthermore, several studies suggest
83 that cancer may be diagnosed at a later stage in patients with disabilities, and that
84 they experience treatment disparities resulting in higher cancer-specific mortality
85 rates. (24,25) A recent meta-analysis from the USA showed that women with
86 disabilities have 0.78 (95% CI: 0.72-0.84) lower odds of attending breast cancer
87 screening and have 0.63 (95% CI: 0.45-0.88) lower odds of attending cervical cancer
88 screening, compared to women without disabilities. A recent study from Taiwan
89 reported that the probability of receiving colorectal cancer screening in people in the
90 four categories of disability (intellectual and developmental disability, dementia,
91 multiple disabilities, and moving functional limitation; OR = 0.53, 0.55, 0.62 and 0.81,
92 respectively) was significantly lower than that in the general population. (25,26) Two
93 recent scoping reviews found that patients with intellectual disabilities may be at risk
94 of experiencing inequities at various points during cancer clinical pathways, which as
95 a consequence could have an impact on their overall and cancer-specific mortality
96 and quality of life; it is thus of the outmost importance to identify and address these
97 disparities. (24,35) Consequently, the aim of this study is to conduct a systematic
98 literature review to compare cancer outcomes and quality of cancer care between
99 adults with and without disabilities.

100

101 **Materials and methods**

102 A systematic review of the literature was conducted describing differences in cancer-
103 related care between patients with and without disabilities, according to the PRISMA
104 reporting guidelines; the study was recorded on the NIHR Prospero register of

105 systematic reviews with ID number CRD42022281506 . (27, 28)

106 **Search Strategy**

107 We used a systematic literature review to achieve our aim and objectives. The
108 review was performed on July 1st 2022, across 5 databases: EMBASE, Medline,
109 Cochrane Library, Web of Science and CINAHL databases. We included search
110 terms on: disability (physical, sensory, psychological, communication and/or
111 cognitive disability; measured clinically or through self-report); and cancer treatment
112 (surgery, radiotherapy, chemotherapy, palliative care for any type of cancer), limited
113 to the past 22 years (2000-June 2022), and to English language because of resource
114 challenges with respect to costs, time, and expertise in non-English languages. The
115 full search strategy can be found in the supporting information S1 file.

116 Eligible studies included quantitative studies (observational or interventional),
117 conducted in adults aged 18+, allowing comparison of cancer outcomes between
118 PwD (of any type) and those without disabilities. The disability definition had to be in
119 agreement with the International Classification of Functioning, Disability and Health
120 (ICF) framework (i.e. including impairment, activity limitations or participation
121 restriction due to an underlying health condition in interaction with personal and
122 environmental barriers).(29) Studies had to include one or more measures of
123 outcomes along the cancer clinical pathway of diagnosis, treatment, and follow-up or
124 end-of-life care. Eligible outcomes were overall mortality after cancer diagnosis,
125 cancer-related mortality, survival, access to state-of-the-art treatment (defined as
126 intent-to-cure treatment when feasible or guideline-consistent stage-appropriate
127 treatment), type of treatment received (medical vs surgical vs radiation vs.
128 hormonal), invasiveness of treatment, delay of treatment, specialist care utilization,

129 access to pain control prescription and end-of-life hospital use for palliative care.
130 Studies focused on screening for cancer were not eligible, as this question was
131 recently reviewed(33-36) There were no geographic restrictions.

132 Types of study excluded were editorials, commentaries, opinion papers, reviews,
133 case reports, case series under 10 patients and conference abstracts. Studies with
134 patients under age 18 in a pediatric setting, studies without a measure of disability,
135 studies that did not include a sample of patients with disabilities and a sample of
136 patients without disabilities and studies without outcome measures for cancer care
137 were also excluded. According to these criteria, studies with ineligible design,
138 comparator, population, outcomes, intervention or setting were excluded. (Figure 1)

139

140 **Study selection**

141 All studies identified through the searches were exported to a Mendeley bibliographic
142 database for deduplication and to Covidence software for screening. One author (IT)
143 screened studies by title and abstract and full text to determine eligibility. Decisions
144 to include were made according to inclusion criteria.

145

146 **Data extraction and analysis:**

147 A table was created for data extraction (Table 1 in Supplement1) listing authors, year
148 of publishing, country where the study was undertaken, study design, type of cancer,
149 type of disability, type of outcome, population size and overall risk of bias. One
150 author (IT) extracted the data. A summary of study characteristics can be found in

151 Table 1.

152 We also created a table with a summary of primary and secondary outcomes of each
153 study (Table 2); where possible, odds or prevalence ratios as a measure of
154 association or p -values comparing measures in people with and without disabilities
155 were extracted. Each study was also classified as “better”, “worse” or “null”, when
156 outcomes respectively showed a better, worse or equal situation in quality of cancer
157 care for PwD in comparison to people without disabilities.

158 A narrative synthesis was conducted according to the Cochrane SWiM guidelines.

159

160 **Determining risk of bias:**

161 Studies were evaluated for risk of bias based on a set of criteria according to the
162 SIGN 50 (Scottish Intercollegiate Guidelines Network) checklists as explained in
163 Supplement 1. (37)

164 Overall Ratings were summarised as follows (figure 2) with RobVis tool:(38)

165- Low risk of bias: all or almost all of the above criteria were fulfilled, and those that
166 were not fulfilled were thought unlikely to alter the conclusions of the study;

167- Medium risk of bias: some of the above criteria were fulfilled, and those not fulfilled
168 were thought unlikely to alter the conclusions of the study;

169- High risk of bias: few or no criteria were fulfilled, and those that were not fulfilled
170 were thought likely or very likely to alter the conclusions of the study.

171 We did not perform tests to measure publication bias.(39)

172 **Ethical Considerations**

173 Approval for the review was given by LSHTM MSc Ethics Board (internal ref. 26741).

174 There were no ethical concerns for this literature review.

175 **Financial support and Competing Interests**

176 The Authors declare no competing interests; there are no known conflicts of interest

177 associated with this publication and there has been no significant financial support

178 for this work that could have influenced its outcome.

179 .

180

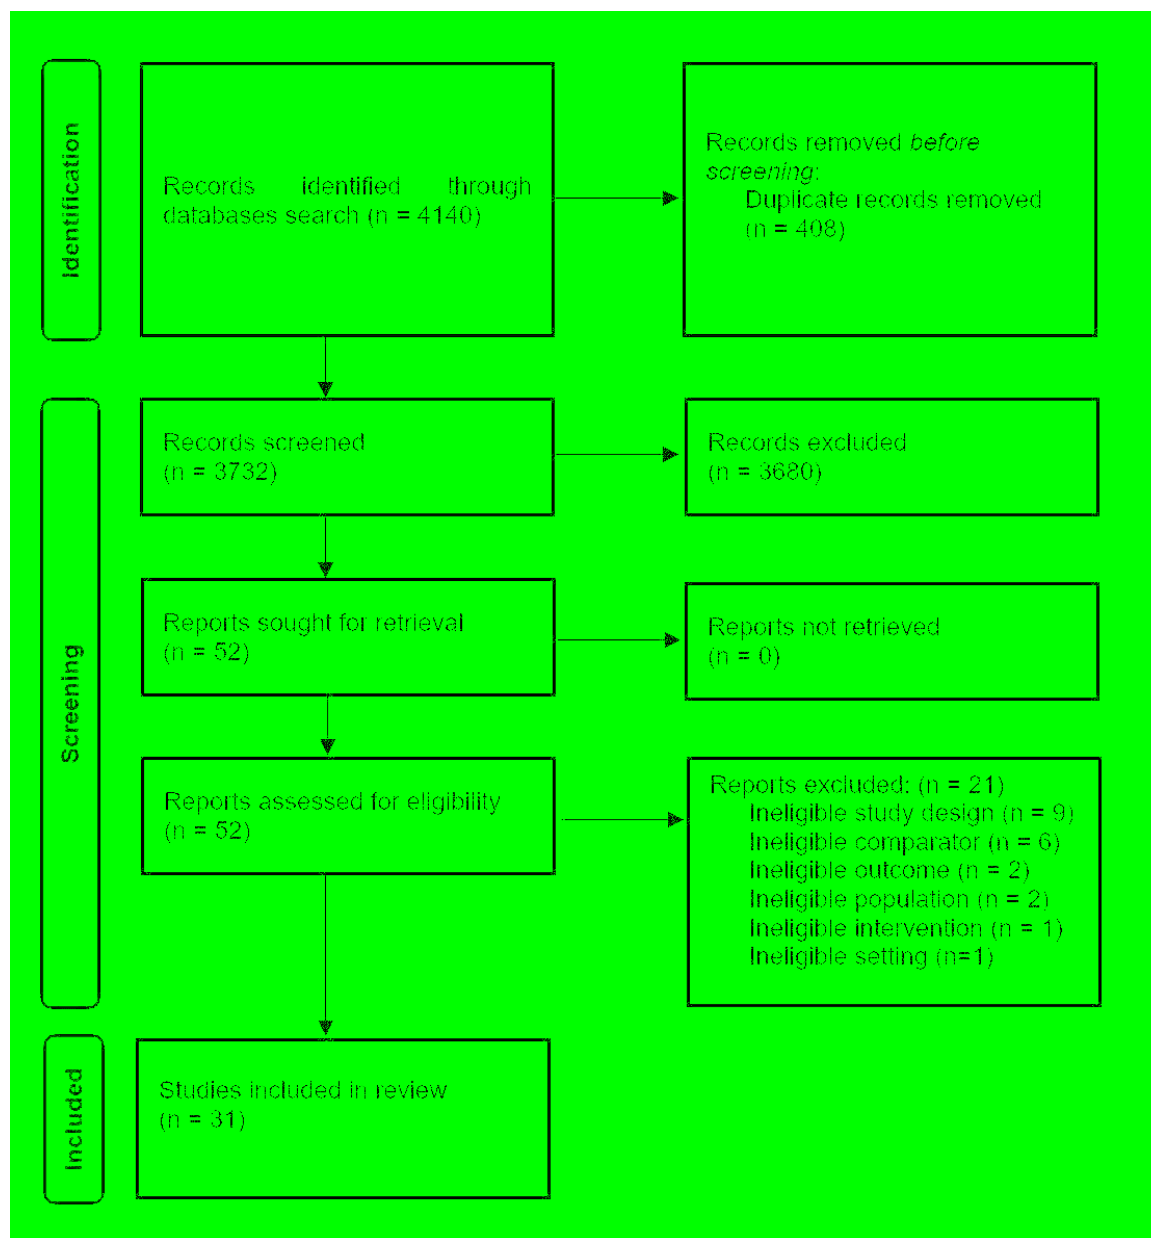

181

182

183 **Results**

184 The search was conducted on July 13th, 2022 resulting in 4140 titles identified
185 (Figure 1). After removal of 408 duplicates, 3732 titles and abstracts were screened,
186 and 3680 ineligible studies were excluded. Next, 52 full texts were retrieved and 21
187 were excluded because of ineligible study design, comparator, patient population,
188 outcomes, intervention or setting. Finally, 31 studies were identified as eligible for the
189 systematic review.

196

197 **Study Characteristics**

198 Table 1 shows a summary of the characteristics of the 31 studies included in the
199 systematic review. All the studies were conducted in high-income countries, with the
200 greatest proportion coming from the USA (29% of the studies, n=9), followed by
201 South Korea (19%, n=9), Japan (13%, n=4), France (10%, n=3), then by the UK,
202 Netherlands and Sweden with two studies each, and by Belgium, Taiwan and
203 Germany with one study each. Twenty studies (65%) were published after 2018,
204 showing a marked growth in research interest on this topic in the past few years;
205 only 11 eligible studies were published earlier, between 2000 and 2017.

206 A more detailed table of study characteristics is included in Supplement 1.

219

220 **Study Design**

221 Twenty-seven of the 31 studies used a retrospective cohort study design, with data
222 either from a single center (n= 2) or from a national or multi-center health insurance
223 and disability database (n=25), while three studies used a prospective cohort design,
224 one from a single center and two from multi-center hospital networks. One study only
225 used a cross-sectional design with a survey performed among patients of a network
226 of cancer centers.

227 **Types of Disabilities**

228 Over a third of the eligible studies focused on people with psychosocial disability
229 (42%, n=13) defined as a previous diagnosis of psychiatric or mental health issues.
230 (38–53) Nine studies (29%, n=9) focused on intellectual, learning disabilities,
231 cognitive impairment or dementia(54–62)Nine other studies (29%, n=9) considered
232 all disability in general or grouped into subcategories (e.g.
233 physical/communication/mental/internal organ/others). (19,22-23,63–68) Few studies
234 differentiated by severity of impairment. (19,22,64-69)

235

236 **Types of Cancer**

237 Seven studies (23%) were about any type of malignancy, while almost a third (29%,
238 n=9) were about breast cancer. There were 4 studies (13%) regarding stomach and
239 colorectal malignancies, 3 (10%) on lung cancer, 2 (6%) on prostate cancer, and 1
240 study each for testicular, multiple myeloma (MM), acute myeloid leukaemia (AML),

241 bladder and oral cancer. Finally, one study included patients of breast, prostate and
242 colorectal cancers (Table 1).

243

244 **Types of outcome**

245 The majority of papers (65%, n=20) included a measure of survival or mortality after
246 cancer diagnosis as primary or secondary outcome. Seventeen studies (55%)
247 included an outcome of access to state-of-the-art cancer treatment, measured as
248 type of treatment received (guidelines consistent according to disease stage) or
249 invasiveness of surgery or treatment delay. Four (13%) studies described access to
250 quality of end-of-life care, defined as access to appropriate pain control and end-of-
251 life hospital use for palliative care. One study included access to pain medications as
252 an outcome.

253

254 **Risk of Bias**

255 Almost half of the 31 studies (45%, n=14) had a medium risk of bias, while 12
256 studies had a low risk of bias (39%, n=12). Finally, 5 papers were marked as having
257 a high risk of bias. A summary of the assessment of risk of bias, was created with
258 RobVis tool. (38) (Figure 2)

264 Outcome Results

265 Outcomes are summarized in Table 2. Nineteen studies that included a measure of
266 survival or mortality all showed, invariably, a direction of effect towards worse
267 outcomes for PwD; this was often worsened by the degree of severity of
268 disability.(19,22,41,54-55,62) Only one study found no difference in overall survival or
269 disease-free survival between patients with and without disabilities. (49) Among
270 psychosocial disabilities, schizophrenia had generally the worst prognosis.
271 (41,47,51,66,70) In studies that examined survival in cancer patients with all types of
272 disability, there seemed to be far worse outcomes for those with severe disabilities
273 and with intellectual impairment. In one study results showed that patients with
274 schizophrenia had a cancer specific mortality rate 50% higher than patients without
275 disabilities. (50) In another study about bladder cancer, the risk of cancer specific
276 death was 35% higher for patients with severe mental illness compared to people
277 without disabilities. (69)

278 In a large study about gastric cancer patients in South Korea, PwD were more likely
279 not to
280 receive proper staging tests to establish an appropriate treatment plan. Observing
281 subgroups by disability type, the fact of not receiving treatment was more common
282 for people with communication impairment (36.9%
283 in severe and 31.4% in mild communication disability); the authors concluded that
284 disability itself should not be a
285 contraindication for receiving cancer treatment. (16) Another study about patients
286 with leukaemia described how the treatment rate was lowest in those with major
287 internal organ and communication disabilities; while for patients with major internal

288 organ disabilities it is understandable to have a low treatment rate due to vital
289 functions often lacking functional reserve, communication disabilities are not directly
290 related
291 to vital functions and the decision not to treat was hence not based solely on medical
292 factors. (67)

313 There were 16 studies showing lower chance in receiving state-of-the-art cancer
314 treatment for PwD, and only one study with high risk of bias showed no difference,
315 but data about gender and degree of disability was missing. (64)

316 The studies showed that cancer treatment was suboptimal for PwD in many ways,
317 and in particular that they had a lower likelihood of undergoing guideline-consistent
318 surgery when indicated. (22,23,48,52,61,63,66,70) Several studies showed that when
319 PwD were correctly treated with guideline-consistent surgery, their mortality was
320 similar or only slightly higher than controls. (62,66)PwD were also more likely to face
321 diagnosis and treatment delays - but not when access to screening was optimal,
322 underlining the importance of good screening access. (22,42,43,56,57,71) PwD
323 were also less likely to receive curative-intent transplants for blood cancers, and
324 more likely to receive inappropriate radical mastectomy instead of guideline-
325 consistent minimally invasive procedures for breast cancer (19,44,63,67)

326 As for end-of-life and palliative care, 4 studies showed a direction of effect towards
327 worse outcomes for PwD (40,45,46,58). One of this studies, with low risk of bias,
328 showed an association between receiving outpatient treatment from a mental health
329 professional and having less end-of-life ED visits, suggesting the importance of
330 access to mental health services to improve end-of-life care. (45) One study showed
331 an association between disability and worse access to prescriptions for pain
332 treatment during cancer care, a situation likely to severely compromise quality of life.
333 (59) Finally, a study reported that patients over age 55 with intellectual disability were
334 more likely than controls to have worse access to specialist care in the last year of
335 life. (58)

336 Regarding other factors contributing to worse outcomes, one study showed an
337 association between worse access to screening programs (for breast, colon and
338 cervix cancers) and higher cancer specific mortality, underlining the inequality in
339 screening practices. (56) Two other studies highlighted an association between
340 barriers to screening and worse outcomes for gastric and breast cancer in PwD.
341 (22,44) Two studies detected even worse disparities in access to state-of-the-art
342 treatment or end-of-life care related to ethnicity and age, with young disabled non-
343 white men having the worst outcomes. (45, 62) One study of people with intellectual
344 disabilities with any type of cancer suggested worse underdiagnosis for older
345 females, while another focusing on breast cancer detected an association between
346 physical disability and inappropriate invasiveness of treatment. (55, 63) In a study of
347 non-small cell lung cancer patients, those with respiratory or nervous system
348 disabilities had the lowest chance of receiving guideline-appropriate surgery, while
349 another paper on lung cancer recorded the worst access to treatment among people
350 with communication or neurologic disabilities. (23, 62) A study about stomach cancer
351 and patients with all kinds of disabilities also found an association between worse
352 outcomes and severe intellectual impairment. (22)

353 Finally, three studies showed an association between worse outcomes of treatment
354 access and poverty among people with cancer. (19, 46, 68)

355

356 **Discussion**

357 In our review, compared to people without disabilities, PwD were found to have
358 worse survival, higher overall and cancer-specific mortality, loss of chance for

359 access to state-of-the-art care or curative-intent therapies, treatment delays,
360 undertreatment or excessively invasive treatment, worse access to in-hospital
361 services, less specialist healthcare utilization, more difficult access to pain
362 medications and inadequate end-of-life quality of care. Only one eligible study found
363 no difference in overall survival or disease-free survival between patients with and
364 without disabilities; it was a small paper with a high risk of bias, with a cohort
365 including only operable breast cancer in a small number of patients, and it still
366 showed an association between disability and excessively invasive breast surgery
367 without any clear cancer-related clinical reason. Furthermore, the incidence of
368 disability in its retrospective cohort was inexplicably only half of the known national
369 incidence, suggesting severe misclassification bias. (49)These finding suggest that
370 differences in frequency of appropriate treatment appear to explain the higher
371 cancer-specific mortality for this vulnerable population, with higher mortality likely
372 due to loss of chance and unequal clinical care. Even if sometimes treatment
373 decisions for PwD can be clinically complex, such as the above-mentioned case of
374 cognitive impairment with legal consent or non-compliance issues, or when
375 confronted with a disability-related shortened life expectancy or frailty for some
376 syndromes, there is no plausible medical justification for such a wide disparity
377 compared to patients without disabilities, and these results raise severe concerns
378 about equality in cancer care.(25-26,70-74)

379 The results of this study are consistent with those of other recent literature reviews,
380 showing that PwD experience inequities at several points throughout the cancer care
381 pathway. (12,24,26,73-74) Screening disparities have been known and documented
382 for years: they can vary by disability type, severity, healthcare offer and social or
383 demographic situations, with some differences across countries, but globally there is

384 a largely similar trend of major barriers to screening for people with disability,
385 showing a clear need to improve the inclusiveness of these early-diagnosis
386 services.(12, 71-75)

387 Providing equitable cancer care has to start early in the cancer clinical pathway,
388 because delays in receiving a diagnosis tend to lead to late access to treatment and
389 worse outcomes.(70-74) A frequently observed issue is that new signs and
390 symptoms tend to be attributed to often to the underlying disability, a clinical mistake
391 called “diagnostic overshadowing”. (72-76) A recent scoping review about cancer
392 outcomes in adults with intellectual and developmental disabilities has described
393 disparities at every step of the way, from screening, to staging, to treatment and
394 survival outcomes, recognizing how these experiences do not originate simply from a
395 gap in early diagnosis, but from larger structural issues that ultimately hinders quality
396 of the entire cancer care pathway. (74,77) Another review of cancer treatments for
397 people with intellectual disabilities highlighted possible themes that might interfere
398 with treatment, such as genetic syndrome frailty that might render certain drug
399 treatments too dangerous, the issue of behavioral non-compliance in a subgroup of
400 patients, and problems related to legal capacity and obtainment of informed consent.
401 Still, these three factors should not represent an insurmountable barrier because
402 with appropriate arrangements (e.g. pharmacology consults, procedural sedation,
403 legal assistance) it should still be possible to offer guideline-consistent treatment to
404 patients.(25-26) With physical disabilities clinical decisions can sometimes be
405 objectively more difficult than in people without disabilities, because of concerns
406 about baseline performance status or competing health risks due to invasive or toxic
407 treatments that might result in further dramatic loss of function (e.g. possible loss of
408 postoperative upper limb function after breast surgery in patients with previous spinal

409 cord injury and lower limb paralysis); this has been described as a compelling reason
410 to move towards better cooperation between cancer care clinicians and disability
411 specialists who have been in charge of the patient well before their oncology
412 episode, and also as one of the fundamental facts that make shared decision making
413 with patients (or sometimes their families or caregivers) of the utmost
414 importance.(12)

415 This clear evidence of inequities emphasizes the very urgent need for better cancer
416 care for PwD. Furthermore, disparity in healthcare for PwD is not unique to oncology,
417 as research about the recent Covid-19 pandemic has clearly proven. (77-82) During
418 the pandemic, PwD have died in disproportionate numbers – almost three times as
419 much globally than people without disabilities - and have been excluded from the
420 decision-making process, because their needs have been ignored; they have ended
421 up facing an increasing amount of psychological distress, lack of social support,
422 extreme isolation, food insecurity, disparities in health care access and even
423 discrimination at work. In many cases, government response has compromised the
424 human rights of disabled people, having exposed and magnified existing structural
425 failings and inequalities.(80-85)

426 Recently, the second report of the Missing Billion Initiative has called for reimagining
427 health systems with a vision of inclusive health informed by diverse perspectives of
428 PwD, who are still facing worse health outcomes across SDG3 indicators
429 (Sustainable Development Goal 3 by the WHO, i.e. ensure healthy lives and
430 promote well-being for all at all ages), globally and with all sort of impairment
431 types. (84) The first Missing Billion report had highlighted a substantial life
432 expectancy gap of 10-20 years for PwD, with all-cause mortality rates

433 approximately twice as high as those of people without disabilities.(83) Closing this
434 gap is now a priority, but it requires long-term investments to design from the start
435 health systems that expect, accept and connect PwD, with sufficient earmarked
436 funds, dedicated leadership and clear governance based on data and evidence
437 disaggregated by disability. Ideally service delivery should aim at affordability,
438 autonomy of patients, accessibility, specific workforce skillsets and availability of
439 rehabilitation services. (82-86) The multiple barriers experienced by PwD during
440 their cancer care (Figure 3) are hence a reflection of a broader process of
441 discrimination and disadvantage, mirrored in structural failings of current healthcare
442 systems, within networks of intersecting factors that ultimately influence cancer
443 outcomes. (24, 82-87)

444

445 **Figure 3: Barriers experienced by PwD during cancer care**

446

447

448 Healthcare workers need to receive evidence-based and appropriate training about
449 disabilities, directly involving PwD and using a monitoring system to measure cultural
450 progress and outcome improvement. This could help foster a change to move away
451 from the ableist attitudes that are too often still observed, contributing to wrong
452 assumptions and subsequent mistakes of diagnostic overshadowing or failure to
453 anticipate specific complications (12,75,86-88). In a very recent qualitative study from
454 the USA, interviewed physicians, mostly middle-aged white males, felt inadequately
455 reimbursed for accommodations required by the 1990 Americans with Disabilities
456 Act; according to some of these doctors, these concerns simply led them to
457 discharge patients with disabilities. (86) Many physicians openly spoke about the
458 lack of accessibility in their clinics without any plans to improve it, and several

459 demonstrated a complete lack of disability knowledge about how to manage very
460 basic issues – even stating that they were regularly sending patients to a zoo, cattle
461 processing plant or supermarket to obtain a weight if a patient was in a wheelchair
462 and unable to stand; several doctors admitted that they rarely spoke to these
463 patients, regardless of the patients' ability to communicate, and that information was
464 almost exclusively obtained from the caregiver. This confirms findings from previous
465 qualitative research, that had described a lack of skills by healthcare workers to feel
466 empathy for the embodied experience of living with a disability, with an obstinate
467 resistance to adapting their habitual practice to these patients. (10)

468 The importance of inclusive clinical trials to close the evidence gap about what works
469 to improve cancer care for PwD cannot be overemphasized (86-90). There is still too
470 little evidence about how to treat cancer in the population with disabilities, which is
471 very diverse and can have widely different therapeutic needs (hence existing
472 services must be offered in a flexible, respectful, inclusive and accessible way to be
473 relevant for this patient population). Thus it is of the utmost importance to include
474 PwD in clinical trials in oncology - both for curative-intent interventions and for
475 palliative treatments; yet, historically they have been left out of studies, due to many
476 factors such as ableist prejudice, or multiple barriers such as accessibility of
477 research facilities and access to transportation, or lack of caregivers' engagement.
478 (87-92) Unfortunately, in clinical trials pre-existing conditions are often excluded,
479 even if the conditions have little bearing on the treatment being tested or the
480 outcome of the trial. Excluding disabled individuals from a study can result in a study
481 population that does not even represent the general population, since disability often
482 correlates with other inequalities (such as poverty and unemployment). The
483 importance of targeting the recruitment of disabled individuals into clinical trials, as

484 well as considering the unique barriers and motivations of this population, needs to
485 be highlighted. A person with a disability may have difficulty traveling to a trial site;
486 moreover, healthcare organizations should consider their audiences' digital literacy
487 and the accessibility of their communications. Funds should be allocated to improve
488 healthcare communication, adapting multiple formats, using captions and alt-text or
489 pictorial representations of concepts as appropriate for the specific context. In
490 addition, disabled individuals appear to be underrepresented as investigators in
491 scientific research.(89-93) Despite 19% of the UK's general population identifying as
492 disabled, only 4% of academic, research, and teaching staff do. Even if 25% of
493 American adults live with a disability, in 2020 only 4% of US STEM PhDs were
494 awarded to people with impaired hearing or vision, and just 1% to people with a
495 mobility limitation. More disability-confident schemes and unconscious bias training
496 could at least partially mitigate hiring discrimination, creating an academic workforce
497 that better reflects the community in which it is based.(90-94) Recent evidence-
498 based recommendations to promote inclusion in clinical trials include improving
499 culture and sensitivity of staff through continuous education, receiving ongoing
500 feedback from a community advisory panel during studies and increasing staff
501 diversity to make sure underprivileged groups are represented. (91-94)

502 Physicians and PwD should be able to collaborate along care pathways with shared-
503 decision making, an approach based not only on clinical technical advice but on the
504 life experience of patients, their caregivers and families, according to the principle of
505 “Nothing About Us Without Us”.(12) In the clinical setting, barriers in physical access
506 should be removed to avoid unacceptable delays in diagnosis and treatment.(10, 91-
507 94) Barriers in communication should be eliminated at several levels, from
508 overcoming communication obstacles (not only for the hearing or visually impaired

509 patients, but also with special-needs assistance for intellectual disability), to
510 improving education of patients, clinicians and caregivers about cancer and the
511 importance of screening, to training healthcare workers about the emotional and
512 physical needs of PwD, enhancing cooperation with other specialists caring for them,
513 in cross-functional teams, to anticipate and possibly reduce the impact of
514 complications, with the goal of a patient-centred pathway. (93-94) Good
515 communication is the foundation of achieving quality patient-centered care:
516 assumptions about preferences can pose a risk like inaccurate information leading to
517 medical errors and misdiagnoses. A recent qualitative study in the USA has shown
518 that, in spite of healthcare workers trying their best, there are still many unsolved
519 issues at this level and even many situations where physicians' preferences go
520 against patients' wishes. (91-94)

521 The strengths of this study include having followed PRISMA and ICM50 guidelines
522 for systematic reviews; furthermore, the search strategy was based on a list of
523 proven disability-specific terms and applied to the five largest medical databases
524 analysing a twenty-year span of publications. This work has several limitations:
525 firstly, the search strategy, limited to five databases and to English language only,
526 might not be fully comprehensive; we did not include studies published in non-
527 English languages because of resource challenges with respect to costs, time, and
528 expertise in non-English languages, but their inclusion would have likely increased
529 generalizability and reduced the overall risk of bias. Furthermore all the eligible
530 papers were from high-income countries, limiting the generalizability of the results,
531 even if there is no reason why the situation should be very different in low and
532 middle-income countries., Qualitative papers and grey literature were not included in
533 the search strategy, hence the views and opinions of PwD about their cancer care

534 were not investigated. Study selection was performed by only one reviewer, which
535 implies a lack of independent screening. We also did not perform tests to measure
536 publication bias due to the high heterogeneity of the eligible studies; although
537 methods exist for simultaneous assessment of heterogeneity and publication bias,
538 and potential differential publication bias, they require very large meta-analysis to
539 reliably disentangle their effects.(39) Moreover, only one reviewer evaluated papers
540 for risk of bias. Finally, the findings were very diverse hence it was not possible to
541 conduct a meta-analysis, and approximately 15% of the studies had a high risk of
542 bias. Almost half (45%) of the eligible studies had a medium risk of bias, mostly due
543 to possible misclassification bias for inclusion of PwD based on disability records
544 (that have a tendency to miss mild cases) CIT or missing data like details about
545 cancer treatment goals, behavioral factors or date of diagnosis. Approximately 15%
546 of the studies had a high risk of bias due to factors such as having a very small
547 sample size, a short follow-up, low data quality, a biased cohort or using a self-
548 reporting survey. (44,49,57,63,64)There are still gaps in knowledge about quality of
549 cancer care for people with disability that remain unanswered based on our findings,
550 such as whether certain subgroups of disabilities or cancer types experience more
551 significant disparities, or how other social determinants of health might come into
552 play (as many PwD are caught in a cycle of poverty and deprivation); more data is
553 needed on these topics to allow disaggregated analyses. Further research is also
554 needed to evaluate the effectiveness of specific training of healthcare workers on
555 quality of care for these patients.

556 In conclusion, PwD often experience severe disparities in cancer care compared to
557 people without disabilities; physical and cultural barriers at different levels must be
558 eliminated to ensure they receive equitable care. There is an urgent need for a

559 robust health policy effort by governments, reimagining health systems with a vision
560 of inclusive health and a sustained commitment, building on decades of progress on
561 disability rights and engaging the participation of PwD at all levels.

562

563 **Acknowledgments**

564 I.T. would like to thank Danae Rodriguez Gatta, for assistance with disability search
565 terms, and Dr. Meena Cherian, for many fruitful discussions about health systems
566 and development goals.
