Abstract

Objective

Chronic kidney disease (CKD) and chronic kidney disease of uncertain etiology (CKDu) are chronic kidney diseases that pose a significant health burden in Sri Lanka. Leptospirosis is a bacterial zoonosis that primarily damages renal tissues by colonization of *Leptospira* spp. in the renal tubules and is a suspected etiological agent of CKDu. Since Sri Lanka is an endemic for leptospirosis and outbreaks of the disease have been reported, this study aimed to determine the association between leptospirosis and chronic kidney disease in two geographically distinct regions of Sri Lanka, Badulla (CKDu endemic) and Kandy (CKDu non-endemic) districts.

Results

Eighty-five patients with CKDu and 149 controls from Badulla and 49 patients with CKD and 135 controls from Kandy were serologically tested by microscopic agglutination test with a panel of 11 *Leptospira* serogroups. The seroprevalence rates for leptospirosis were 7.1% and 13.4% in the CKDu and control groups, respectively, in Badulla and 2.1% and 18.5% in the CKD and control groups, respectively, in Kandy. There were no statistically significant differences between demographic characteristics and leptospirosis seropositivity in the CKD and control groups in either Badulla or Kandy.

Keywords

chronic kidney disease, chronic kidney disease of uncertain etiology, leptospirosis, Sri Lanka

Introduction

Chronic kidney disease (CKD) is a global public health problem primarily caused by due to diabetes and hypertension. CKD is defined as any condition that damages kidney tissue and results in a decrease in renal function with a glomerular filtration rate (GFR) of $<60 \text{ mL/min/1.73 m}^2$ for ≥ 3 months [1]. CKD that occurs in the absence of diabetes, hypertension, and other known risk factors is referred to as chronic kidney disease of uncertain etiology (CKDu) [2]. CKDu has been reported in Central America, Egypt, India, and Sri Lanka [3–6]. While several hypotheses are being explored to determine the causative agents/factors responsible for CKDu, one hypothesis that has been overlooked in Sri Lanka is an infectious etiology, such as hantavirus infection and leptospirosis [7].

Previous studies have implicated leptospirosis as a possible etiological agent or risk factor for CKDu [7–10]. Leptospirosis is one of the most prevalent bacterial zoonoses worldwide and is caused by spirochetes of the genus *Leptospira* [7]. The kidney is the primary target organ of *Leptospira* spp. If left untreated, the bacteria can colonize the renal tubules of the kidney tissue [10]. Renal colonization by *Leptospira* spp. can lead to interstitial tubular nephritis and acute kidney injury (AKI), which carry a risk for CKD [10]. Long-term mild subclinical AKI may lead to the development of CKD [11]. In 2015, an association between CKD and leptospirosis was first suggested in Taiwan: participants exposed to *Leptospira* spp. showed a 2.5% decrease in estimated GFR and a higher percentage of CKD compared to those not exposed to the bacteria [12]. In the same study, 88 individuals with high anti-leptospiral antibody titers were followed up for two years, and individuals with microscopic agglutination test (MAT) titers > 400 showed a positive correlation with the kidney injury marker KIM-1/Cr [12]. In 2018, Yang presented two hypothetical pathways by which leptospirosis could progress to CKD: acute *Leptospira* infection could progress to chronic leptospirosis if left untreated, leading to the development of CKD, while subclinical *Leptospira* infection could lead to chronic leptospirosis that may progress to CKD [10]. Heat stress and dehydration have been postulated to have synergistic effects on these pathways [10]. Furthermore, there are several similarities between leptospirosis kidney disease and CKDu, such as

tubulointerstitial nephritis, interstitial fibrosis, non-proteinuria, proximal tubule dysfunction, and hypokalemia, and both diseases affect middle-aged men living in hot climates [10].

Although leptospirosis is an endemic and notifiable disease in Sri Lanka, it is still largely underdiagnosed and therefore most likely untreated, which can lead to a chronic state of infection without symptoms. The highest burden of CKDu occurs in the North Central Province (NCP), where leptospirosis outbreaks are also common [13, 14]. Since most of the CKDu affected population in the NCP are middle-aged men working in agriculture, it is possible that the renal tissue damage caused by *Leptospira* infection may progress to a chronic state due to incomplete recovery from mild AKI, recurrent exposure to *Leptospira* spp., and heat stress and dehydration. Therefore, this study investigated the involvement of leptospirosis as a causative agent or risk factor for CKD by comparing the seroprevalence of leptospirosis between chronic kidney disease patients and healthy controls in a CKDu endemic district, Badulla, and a CKDu non-endemic district, Kandy, Sri Lanka.

Main Text

Methods

Study design

This is a hospital and community-based cross-sectional study with unmatched cases and controls. The study areas were Mahiyangana Divisional Secretariat, Badulla district, an endemic region of CKDu, and Yatinuwara Divisional Secretariat, Kandy district, a non-endemic region of CKDu, Sri Lanka.

Sample collection

Sample collection was conducted between January 2017 and February 2018. Clinically diagnosed CKDu patients aged ≥ 18 years residing in Badulla (n=85) and CKD patients aged ≥ 18 years in Kandy (n=49) districts and attending the renal clinics of the Nephrology and Transplantation Unit, Girandurukotte District Hospital (Badulla) and Teaching Hospital Kandy (Kandy), respectively, were recruited as cases for the study. Individuals with a history of alcoholism were excluded from the study. For the control groups, the Medical Office of Health areas within the Badulla and Kandy districts were randomly selected. Individuals aged ≥ 18 years, residing in Badulla (n=149) and Kandy (n=135) districts, with no clinically diagnosed renal disease and normal serum creatinine levels (0.5–1.2 mg/dL) volunteered to participate in this study. Individuals with a history of either alcoholism or kidney disease were excluded from the study.

Five milliliters of blood were collected in sterile tubes without anticoagulant. The tubes were left undisturbed at room temperature for 30 min and centrifuged at 2000×g for serum separation. Serum separation was performed at the sample collection site and immediately transported in insulated coolers to the Department of Microbiology, Faculty of Medicine, University of Peradeniya, and serum samples were stored at -20°C prior to analysis.

At the time of sample collection, demographic information was collected using a structured questionnaire. The questionnaire covered the following information: basic demographic data (age and sex), family and past medical history, occupational information, agricultural activity, and exposure to rodents.

Detection of anti-leptospiral antibodies by MAT

The MAT panel antigens used in this study were obtained from the Veterinary Research Institute and contained 12 serovars belonging to 11 serogroups: serogroup Autumnalis (serovar Autumnalis), Bataviae (Bataviae), Canicola (Canicola), Grippotyphosa (Grippotyphosa), Hebdomadis

(Hebdomadis), Javanica (Javanica), Panama (Panama), Sejroe (Hardjo and Wolffi), Semarang (Patoc), Shermani (Shermani), and Tarassovi (Tarassovi). The strains were maintained in a liquid Ellinghausen McCullough Johnson and Harris medium supplemented with *Leptospira* enrichment (BD Difco, USA) and 5-fluorouracil (final concentration of 200 µg/mL). Four- to seven-day-old cultures with growth equivalent to 0.5 McFarland (approximately 1-2×10⁸ organisms/mL) were used for MAT as previously described [15, 16]. A MAT titer of ≥1:400 was considered as positive for acute leptospirosis, as a titer of ≥1:320, is considered clinically significant in Sri Lanka [17].

Statistical analysis

All statistical analyses were performed using the Statistical Package for the Social Sciences version 25 (IBM, USA) and the online tool MedCalc (<https://www.medcalc.org/>). Exposure to *Leptospira* spp. and possible risk factors were evaluated by 2×2 Yate's corrected chi-square test or Fisher's exact test. A P value less than 0.05 was considered statistically significant. The odds ratio and associated 95% confidence interval (CI) were calculated in the exposed group when compared with the non-exposed group for *Leptospira* spp.

Results

Leptospirosis seroprevalence in Badulla and Kandy

The seroprevalence rates in the CKDu and control groups in Badulla were 7.1% and 13.4%, respectively (Table 1). There was no statistically significant difference between the disease and control groups (p=0.14). Seroprevalences of 2.0% and 18.5% for leptospirosis were observed in the CKD and control groups, respectively, in Kandy (Table 1). The seroprevalence in the CKD group was significantly lower than that in the control group (p=0.02).

156

157 Discussion

158 This study suggests that there is no association between CKD and leptospirosis seroprevalence. This
 159 finding is consistent with that of a recent study conducted in the NCP of Sri Lanka in 2020, where the
 160 difference in leptospirosis seroprevalence between the CKDu and control groups was not statistically
 161 significant [18]. On the other hand, these results contradict the findings of a study conducted in
 162 Taiwan, which showed an association between *Leptospira* seroprevalence and CKD and lower eGFR
 163 [12]. The cause of CKDu may vary regionally and be geographically specific. Epidemics of kidney
 164 disease of unknown etiology have previously been reported: Itai-itai disease and Balkan endemic
 165 nephropathy (BEN) are nephropathic epidemics whose etiology was identified much later. Itai-itai
 166 disease, which occurred in Japan in 1912, was found to be caused by cadmium poisoning in 1968,
 167 while BEN, which occurred in the 1950s, was found to be caused by aristocholic acid in 1993 [19].

168 This study showed that the predominant infecting *Leptospira* serogroup was Sejroe, of which serovar
 169 Hardjo was the most reactive serovar in both Badulla and Kandy (Table 3 and Supplementary Table
 170 1). Serovar Hardjo is known to be maintained by cattle and the transmission of this strain to humans
 171 often occurs through contact with cattle [20]. The high seroprevalence for serogroup Sejroe (serovar
 172 Hardjo) can be explained by the exposure of the population to agricultural activities with
 173 direct/indirect contact with cattle in Badulla (Table 2). However, a high seroprevalence for serogroup
 174 Sejroe (serovar Hardjo) was also observed in the Kandy population, although most of them were not
 175 involved in agriculture (Table 2). Hardjo infections in dogs and cats have been reported previously in
 176 Brazil, Croatia, Italy, Scotland, and the USA [21–27]. In addition, a previous serological study of
 177 companion dogs in Kandy district showed that Sejroe was the most prevalent serogroup [16].

178

179 Limitations

The CKD cohort in this study consisted of CKD and CKDu patients, whereas it would have been ideal to recruit only CKDu patients. Differentiation between CKDu and CKD patients is possible only by renal biopsy, an invasive procedure that is rarely performed in Sri Lanka. The antigen panel used for MAT was not composed of locally isolated strains. It has been shown that renal colonization with *Leptospira* spp. can occur asymptotically and sometimes in the absence of serological evidence [12, 28, 29]. To conclude that leptospirosis is not associated with CKD in Sri Lanka, renal colonization needs to be investigated.
