29 **ABSTRACT**

30 Yellow Fever virus remains the most medically significant Arbovirus in Africa, with the
31 occurrence of large outbreaks with human fatalities in recent years in Africa. Molecular
32 epidemiology has shown the presence of 4 genotypes circulating across Africa; however, paucity
33 of data still exists regarding directional spread and phylogeography of the African Yellow fever
34 genotypes. The need to fill this gap with information from spatiotemporal data from continuous
35 occurrence of YF outbreaks in Africa conceptualized this study; which aims to investigate the
36 most recent transmission events and directional spread of YF virus using updated genomic
37 sequence data. Archived Yellow Fever sequence data was utilized along with epidemiologic
38 data from outbreaks in Africa, to analyze the case/fatality distribution. Phylogeographic analysis
39 was also utilized to demonstrate the ancestral introduction and geographic clustering of YF
40 genotypes in Africa. Directional spread and geographic transmission of YF was also
41 investigated. African YF genotypes were found to be geographical distinct, circulating within
42 distinct geographical boundaries. Spatiotemporal spread however revealed an eastward spread of
43 the West African genotypes over time, and recent northward movement of the East African
44 genotype. We conclude by recommending expanded human/ vectoral surveillance of YF and
45 other Arboviruses of public health importance, and upscaling sequencing capabilities of new and
46 existing public health labs in Africa to help in the defense against public health threats.

47

48

49

50 **INTRODUCTION**

51 Yellow fever virus is the causative agent for yellow fever, a viral illness that affects mainly the
52 liver, and may cause serious complications including hemorrhage and death [1]. It is a member
53 of the family Flaviviridae, genus flavivirus, along with Dengue virus, West Nile virus and
54 Japanese encephalitis virus. It is an enveloped virus with a single stranded positive-sense RNA
55 genome of 11kb size, that encodes a single polyprotein that is cleaved into 3 structural proteins,
56 envelope (E), matrix (M), and capsid proteins (C) and 7 non-structural proteins, NS1, NS2A,
57 NS2B, NS3, NS4A, NS4B, and NS5 [2]. Yellow fever is an arthropod borne infection,
58 maintained by the mosquito vector *Aedes aegypti*, and *Aedes albopictus*, although several
59 vectorial studies have identified YF virus in other mosquitoes' species, such as *Aedes taylori* [3].
60 The main vector of the YF virus is also capable of transmitting other viral infections such as
61 Chikungunya (CHIK), Dengue (DENV) and Zika (ZIKV) in tropical and sub-tropical areas [3].

62 There are two major vectorial cycles of YF, the sylvatic also known as Jungle YF maintained in
63 non-human primates (NHP) by the mosquito *Heamgogus spp* [4], the second cycle is the urban
64 cycle where humans are the primary host and are transmitted by the peri urban mosquito *Aedes*
65 *aegypti* [3].

66 Yellow fever virus has one serotype, but phylogenetic analysis has identified up to 5 genotypes
67 West Africa genotype I, East Africa genotype, East Africa/Angolan genotype, South American
68 genotype I and South American genotype II [5]. Previous genetic analysis has shown that these
69 genotypes are geographically defined [6], as have been reported for other viruses [7-9]. Previous
70 reports have also shown the likelihood of YF virus originating from around East Africa before
71 emerging in West Africa. Also, majority of the studies carried out in Africa are directed towards
72 outbreak investigation and genotype identification [6], only very few studies have attempted to
73 investigate spatio temporal dynamics of YF in Africa [6, 10]. In a previous study West African
74 YF sequences were shown to be more divergent with evidence of adaptive evolution to the
75 sylvatic environment [10]. In another study, the phylogeography of YF showed stable population
76 demography, regional confinement of genotypes and zoonotic spillovers from the sylvatic
77 outbreaks in Africa [11]. Yellow fever outbreaks continue to occur in Africa despite availability
78 of vaccine and mass deployment to at risk regions in various African countries [12]. For
79 instance, between 2017 to 2022 there have been outbreaks of YF in 4 different states in Nigeria,
80 with a total of 287 confirmed cases [13,14]. Outbreaks have also been reported in Senegal in
81 2020 with 542 suspected cases and 15 laboratory confirmed cases [15]. There have also been
82 silent outbreaks in Nigeria, with a report among patients presenting with pyrexia of unknown
83 origin [16].

84 The continuous reports of outbreaks of YF virus in different parts of Africa, despite
85 implementation of mass vaccination campaigns calls for attention and motivated the
86 conceptualization of this study. The current study was designed to investigate the relationship
87 between YF field surveillance data and available genomic data to the continuous occurrence of
88 outbreaks in Africa; as well as most recent geographic transmission events of Yellow Fever virus
89 genotypes using updated sequence data.

90

91 **METHODS**

92 **Data curation**

93 Data relating to all reported outbreaks of yellow fever virus infections were collected after
94 database search. The databases that were searched include PubMed, Scopus and Google Scholar.
95 Supplementary Table 1 shows the list of Outbreaks with the corresponding articles they were
96 reported in. Figure 1 shows a world map and with an enlarged map of Africa, with the names of
97 countries labelled within each country's geographical locations.

98 Partial YF, E gene sequences from Africa were downloaded from GenBank, along with
99 sequences that were recovered from returnee traveler from Angola to China after the 2016
100 Angolan YF outbreak that spread to China via international travel [17]. This was done with the
101 help of the NCBI Virus database. The dataset consisted of genome sequences of all archived E
102 gene sequences from Africa, along with whole genome sequences deposited in GenBank, the E
103 gene was selected because it represents the most frequently and consistently sequenced gene
104 region for YF virus. In addition to the sequence data, metadata was also extracted such as sample
105 source, year of isolation, and Country Location of isolation.

106 **Demographic analysis**

107 The number of reported cases and subsequent deaths of infected individuals according to
108 Country and year, were retrieved from the published reports of YF outbreaks in Africa. This data
109 was tabulated and visualized on a global map using R studio (<https://www.r-project.org>). A bar
110 representing African YF cases and deaths according to year of occurrence and Country was also
111 generated in R studio (<https://www.r-project.org>). The methods employed in this report has been
112 published as a preprint in MedRxiv (<https://www.medrxiv.org/node/690912.full>).

113

114 **Phylogenetic analysis**

115 Partial genome sequences downloaded from GenBank were aligned using MAFFT v7.222 (FF-
116 NS-2 algorithm) following default settings [18]. The dataset consisted genome sequences from
117 Africa available in GenBank as at 1st February 2023, along with representative sequences from
118 the Southern America (n =220). Maximum likelihood phylogenetic analysis was performed using
119 the general time reversible nucleotide substitution model after automatic model testing with
120 gamma distributed rate variation GTR- Γ [19] with 1000 bootstrap replicates using IQ-TREE
121 software [20]. The pairwise amino acid distances of the African YF sequences were analyzed in
122 reference to the prototype vaccine Asibi strain (GenBank no: AY640589.1) using MEGA 7 (21).

123 **Phylogeography and Evolutionary analysis**

124 Evolutionary and additional phylogenetic analysis was carried out on African YF strains, using a
125 Bayesian evolutionary approach using Markov Chain Monte Carlo (MCMC) implemented in
126 BEAST version 2.5 [22]. The strength of the temporal clock signal of the dataset was carried out
127 by conducting a regression of root to tip genetic distances against year of sampling analysis
128 using TempEst v 1.5 [23]. For the MCMC run, a total of 110 YF virus partial E gene sequences
129 of 280 nucleotides in length were aligned, consisting 91 African sequences and 19 Chinese
130 sequences from the international outbreak in 2016. A list of the sequences used for the analysis is
131 contained in supplementary table 2. Further analysis was then done using the strict clock with
132 coalescent Bayesian Skyline prior. The MCMC run was set at 100,000,000 states with a 10%
133 burn in. Results were visualized in Tracer version 1.8. (<http://tree.bio.ed.ac.uk/software/tracer/>).

134 Bayesian skyride analysis was carried out to visualize the epidemic evolutionary history using
135 Tracer v 1.8. (<http://tree.bio.ed.ac.uk/software/tracer/>).

136 Geographical coordinates of the locations of the African YF sequences were retrieved from the
137 web with the help of online servers. A phylogeographic tree with discrete traits was constructed
138 using the African YF sequences and their geographic coordinates in latitude and longitude using
139 a Bayesian stochastic search variable selection (BSSVS) model implemented in BEAST 2.5 [22].
140 The resulting tree was annotated in TreeAnnotator after discarding a 10% burn-in. In addition, a
141 continuous phylogeographic tree was also constructed for major African YF genotypes,
142 according to their regions of circulation, WA-I/II, and EA-1/EA-II-Angolan genotypes, using a
143 similar approach for the discrete tree except that a continuous tree trait was selected in creating
144 the BEAST XML file in Beauti. The resulting MCC trees were visualized in ggtree [24].

145 **Geographic dispersal**

146 The transmission histories and geographic dispersal was projected using the Phylogeographic
147 trees (Continuous and Discrete) were loaded unto an online software sever where information
148 such as internal node ages, user determined geographic coordinates e.t.c. and maps these to a
149 world geographic map. rendered into SPREAD4 [25].

150

151 **RESULTS**

152 **Yellow fever outbreak Demography**

153 African Yellow fever demography was re-evaluated with updated data from recent literature [13,
154 26]. There were also silent outbreaks identified from molecular detection from patients with
155 pyrexia of unknown origin in Nigeria [16]. From our analysis, Nigeria remains the country with
156 highest number of cases, with Ethiopia having the least number of cases (Figure 2 top). The case
157 fatality distribution shows that high mortality rates were recorded between 1984 and 1987 Figure
158 2 bottom, with majority of cases arising from Nigeria, Angola and Ghana Supplementary table 1.

159 **Phylogeography and Evolution**

160 Global phylogeny of YF virus revealed that the African viruses clustered within the four major
161 genotypes West African genotype I (WA-I), West African genotype II (WA-II), East African
162 genotype (EA), Angolan genotype or East African genotype II (EA-II). Majority of the African
163 strains fell under the WA-II, while WA-I had the lowest number of viral sequences as shown in
164 Figure 3. There was strict geographic defined phylogenetic diversification as shown by
165 continental clustering of the viruses analyzed in our study with the South American strains
166 clustering within the South American genotype and African strains within the African genotypes.
167 The amino acid divergence of the African YF partial E gene sequences ranged between 0% to

168 5.9%, with the recently isolated West African genotypes displaying very low diversity, while the
169 older East African genotypes having between 1.2% to 5.9% (Supplementary table 3).

170 The root to tip divergence for the African YF sequences showed a positive signal, with $R^2 = 0.11$
171 (Figure 4A). The MCC tree of the African YF isolates showed a similar diversification with the
172 global tree with Senegalese isolates being the most abundant and diversely distributed within both
173 WA-I and WA-II genotype sub-clades (Figure 4 bottom). The evolutionary rate of the African
174 YF viruses was 2.08×10^{-4} , 98% HPD ($8.48 \times 10^{-5} - 3.41 \times 10^{-3}$) substitutions/ site/ year. The
175 time calibrated MCC tree also showed ancestral divergence times for each ancestral node with
176 the earliest ancestor dating back as the year 1140. The WA-I genotype had a time to most recent
177 ancestor TMRCA of 1845, 95% HPD (1795 – 1890), while WA-II had a TMRCA of 1852, 95%
178 HPD (1790 – 1910). The EA genotype on the other hand had a TMRCA of 1760, 95% HPD
179 (1655 – 1850), and EA-II 1940, 95% HPD (1900 – 1970). Other ancestral nodes for the
180 genotypes, particularly WA genotypes displayed high posterior support. The viral population of
181 the African sequences had no population growth between 1930 to 1970 but exhibited a state of
182 equilibrium, a sharp decline in effective viral population was however observed between 1980 to
183 the most recent sampling date (Supplementary Figure 1).

184 **Yellow fever virus geographic dispersal**

185 We explored the pattern of geographic dispersal and viral circulation of YF virus within Africa
186 using both discrete and continuous phylogeographic reconstructions. The discrete model clearly
187 showed major transmission routes between East and West Africa. West African countries of
188 Senegal, Burkina Fasso, and Mauritania all seemed to have outbound transmission linkages to
189 other countries, majorly in East and Central Africa. The strongest transmission links visualized
190 as the width of the connecting cords were seen between, Senegal and DRC, Cote d'Ivoire and
191 Angola, and Mauritania and Angola (Figure 5). The phylogeographic movement seemed to be
192 predominantly from West to East Africa, with only few transition events moving out of East
193 Africa to West African countries. For our continuous phylogeography we ran independent
194 analysis on each the two prevailing genotypes of West Africa and East Africa, giving us two
195 independent results. Our analysis was designed to identify specific viral introductions and spread
196 events from historically endemic areas through time (Figure 6A and 6B). In Figure 6A the
197 continuous spatial dispersion of YF West African genotypes (WAI and WAI), shows that
198 between 1960 and 1980, YF fever spread from Senegal and Mali eastwards into countries such as
199 Nigeria, Ghana, and as far as DRC (Figure 6A). There was also transmission from Nigeria
200 eastwards into Cote d'Ivoire showing some eastward movement as well. The most recently
201 observed transmission route was however, from Ghana into Cameroon and from Ghana back into
202 Nigeria occurring between 1980 to 2021. For the East African genotypes shown in Figure 6B,
203 the epicenter of the EA YF spread was around the DRC and between 1750 and 1910, the
204 genotype was spatially dispersed into majorly East and Central African countries such as Angola,
205 Uganda and Kenya. The most recent special movement of the EA genotype were upward from
206 the DRC into Ethiopia and Sudan, between 1910 and 2010.

207

208

209

210 **DISSCUSION**

211 **General and Molecular Epidemiology**

212 Yellow fever virus was first reported in America around the 15th century by Spanish conquerors,
213 but historical and molecular evidence indicates that the virus first originated in Africa where it
214 was imported into the Americas through the trans-Atlantic slave trade [10, 27], ever since then
215 there has been several large outbreaks in mostly West Africa and parts of Central Africa [28].
216 Yellow fever virus was first isolated from the blood of a Ghanian man called Asibi in 1927 [29].
217 Epidemiological data from previous outbreaks, between 1960 and 2022 reviewed in our study
218 indicates a fluctuating pattern of intermittent outbreaks with its peak at between 1986 and 1988
219 (Figure 1b). There was also an upsurge in cases resulting from a large outbreak in Angola in
220 2015, which spilled over into the Democratic Republic of Congo, followed by Uganda 2016. It is
221 presumed that certain social drivers were largely responsible for this re-emergence of large
222 epidemics in East Africa, these include long term conflict among waring rebels and government
223 forces, human population displacement resulting from conflicts, and improved surveillance
224 activity.

225 Molecular epidemiology of the YF virus was consistent with previous reports [6, 30, 31]. With
226 the African sequences maintaining their geographically defined genotypes (Figure 3). There was
227 one West African genotype II reported from the Central African Republic GenBank accession
228 number GU073130. The virus was isolated from a mosquito in 1974 in Central African Republic,
229 an indication that the WA-II genotype might have been circulating and maintained in the forests
230 of CAR. The EA genotypes I and II were strictly maintained in their geographical region. The
231 majority of the recent sequences were of WA-II, with the genotype dominating the Entire West
232 Africa and parts of Central Africa. The evolutionary rate of 2.08×10^{-4} is lower that of a
233 previous report in Africa of 2.8×10^{-4} [11]. Our result is also lower than that of a study of
234 Brazilian YF isolates of 3.1×10^{-4} [32], but is consistent with that of Sall et al [30] which gave
235 2.10×10^{-4} . This shows that the possible mutation rate of YF virus has remained fairly stable
236 through the years in Africa, and is probably slower than isolates causing outbreaks in South
237 Africa.

238 **Phylogeography and transmission dynamics**

239 There is a paucity of data regarding special epidemiology of Infectious agents in Africa, recent
240 reports from West Africa have shown the significance of molecular biogeography and special
241 epidemiology in tracking rapidly expanding infectious agents within West Africa [33-35].

242 Yellow fever phylogeography have consistently showed a distinct geographically bound
243 diversification [6, 30, 36]. Our present study maintains the same regional clustering of the West
244 African genotypes and the East/Central African genotype as well as the Angolan genotype. The
245 more recent sequences isolated from Nigeria in 2018, clustered within WA-II, having a common
246 ancestral history as other closely related isolates, sharing the same sub-clade with isolates from
247 Senegal, Cameroon, and Burkina Fasso. This observation shows strict geographical conservation
248 probably due to the fact that same genotype has established itself within the Forests and
249 grasslands of Nigeria all the way to Senegal. Previous studies have hypothesized that sustained
250 epizootic transmission cycles within forested regions of Africa have led to YF virus adaptation to
251 its intermediate host NHP and its competent vector *Heamagogous spp* [6]. Also, the fact that
252 humans act as a dead-end host leaves little opportunity for intra-host evolution and diversity
253 among human population. Previous reports have identified key mutational features among
254 African YF isolates that confer a positive selection pressure and may play a role in genotype
255 emergence [10, 36]. The EA-I and the EA-II/Angolan genotypes were in conformity with
256 previously reported geographically defined diversity [6, 30]. The most recently identified strains
257 from outbreak in Angola and Uganda 2015/2016 clustered within separate genotypes.

258 Discrete phylogeography showed active transmission routes within both West Africa and East
259 Africa and between both regions. This is an indication of sustained intra-regional transmission as
260 well as trans regional transmission resulting from constant human movement between West and
261 Central Africa. This observation serves as evidence that YF transmission dynamics is not just
262 influenced by ecological drivers and climatic events that may affect the Forest /Savanah
263 ecosystem as previously reported [37-39], but also by human activity such as international trade
264 and human migration. Continuous phylogeography revealed a gradual temporal spread among
265 the genotypes within their regions of primary emergence. The WA genotypes seemed to have
266 stronger migration events compared to the EA genotypes. The WA genotypes displayed a
267 eastward movement cutting across more than 4 countries within the space of just 40 years from
268 Senegal, Mali axis all the way to Camerron as far east as Angola. This very fast spread of the
269 WA genotype may not be unconnected with the rich vegetation across the region and the
270 successful adaptation of the principal insect vector *aedes egypti* to the urban environment of the
271 cities of West Africa. The EA genotype however displayed a much slower spread rate, with its
272 spread event mainly localized within the Central/East African regions. Although there were very
273 recent introductions northward to Sudan and Ethiopia, this seems to have occurred as isolated
274 incidents. Our results in this study affirms that vegetation plays a vital role in the geographic
275 spread of YF across Africa as there was limited Northward geographic movement of the WA
276 genotypes (Figure 6a). The EA/Angolan genotypes seemed to be restricted in their dispersal
277 activity within the East/Central African region, although some northward movement was
278 observed with spread events into Sudan and Ethiopia, these were just probably isolated
279 occurrences arising from local outbreaks from Sylvatic/Sahvana YF cycle spillovers into human
280 habitation areas.

281 CONCLUSION

282 This study reports the most current data on YF virus phylogeography and transmission dynamics.
283 We have shown that YF virus maintain a strict geographically bound lineage dispersal pattern,
284 with major genotypes circulating within strict regional confines. We also report a major surge in
285 reported laboratory confirmed cases majorly in East Africa, after the year 2015. There was also
286 rapid expansion of the WA-II genotype in the last 4 years. Study limitations include poor
287 genomic surveillance system across Africa, resulting in limited amount of YF sequence data
288 available in open-source data banks. We therefore recommend expanded human and vectoral
289 surveillance of YF outbreaks as well as other Arboviruses of public health importance. We also
290 advocate for upscaling Molecular biology capabilities of existing public health labs both
291 Nationally and regionally to enable rapid genomic sequencing and analysis of samples from
292 Arboviral outbreaks such as YF to help in prevention of future epidemics and protect Africa
293 from existing biological threats.
