25

26 **ABSTRACT**

27 **Introduction:** Social protection interventions have the potential to accelerate progress towards global
28 tuberculosis (TB) targets. We piloted a screening and linkage program at four community health centers
29 (HC) to enroll adults seeking TB diagnostic evaluation services into existing government-supported social
30 protection programs in Uganda.

31 **Methods:** From May-December 2021, health center staff were asked to screen adults being evaluated
32 for TB for eligibility for government-supported social protection programs, and to refer eligible people to
33 a sub-county community development office (CDO) responsible for enrolling community members into
34 government-supported social protection programs. Linkage was facilitated with a transportation
35 reimbursement via mobile money and referral documentation confirming program eligibility. We assessed
36 feasibility using programmatic data and conducted post-intervention surveys to understand experiences
37 with the linkage program.

38 **Results:** Of 855 people undergoing TB evaluation, 655 (76%) adults met criteria for at least one
39 government-supported social protection program. 25 (4%) of those were not interested in referral; the
40 rest were referred to their local CDO. While 386 (61%) of the 630 participants reported to the CDO
41 seeking social protection enrolment, only 122 (32%) of those were ultimately enrolled into a social
42 protection scheme, representing only 19% (n=655) of those eligible. In participant surveys, among those
43 seeking enrolment at the CDO (n=60; 65% of those surveyed), 46 (77%) were not enrolled into a social
44 protection program. Reasons for non-enrollment were either unknown to the participant (n=25, 54%) or
45 due to operational challenges at the CDO including a lack of human resources or available groups join
46 in the social protection program (n=20, 43%). 61 (63%) survey participants indicated that they would not
47 have sought social protection enrollment without the referral program.

48 **Conclusion:** Most adults seeking TB diagnostic evaluation are eligible for and interested in obtaining
49 government-supported social protection. We found facilitated linkage from HCs to CDOs offering social
50 protection services to be feasible, however ultimate enrollment into programs was limited. Additional

51 research is needed to identify strategies to improve access to existing social protection programs for
52 eligible TB-affected individuals.

75

76

77 INTRODUCTION

78 Tuberculosis (TB) remains a major global health issue and among the leading causes of death worldwide.
79 In 2021 alone, approximately 10.6 million people developed TB, causing almost 1.6 million deaths
80 globally in the same year (1). It is well-recognized that TB is as much a social disease as it is infectious,
81 with those affected representing the poorest and most vulnerable individuals in society who
82 disproportionately live in low and middle countries (1,2). In addition to the financial vulnerabilities created
83 by TB disease, evidence suggests that suffering from catastrophic costs due to TB, defined as costs
84 surpassing 20% of annual household income, creates greater risk of adverse TB outcomes such as
85 treatment failure, recurrence, and death, and perpetuates negative financial coping strategies such as
86 dissaving, thus entrenching vulnerable individuals and households deeper into poverty and poor health
87 (3–6).

88
89 Recognizing the interdependence between disease, social determinants of health, and socioeconomic
90 development(5,7), both the United Nation’s Sustainable Development Goals (SDGs)(8) and the World
91 Health Organization’s (WHO) 2015 End TB Strategy(9) encourage the implementation of innovative
92 multisectoral approaches to address the intersection of social determinants of health and illnesses like
93 TB (10,11). Both highlight social protection and poverty alleviation as key strategies for addressing risk
94 factors for acquiring TB and the economic consequences that follow its diagnosis (8,9). Social protection
95 is defined as social and economic policies and programs that target multiple dimensions of poverty among
96 disadvantaged groups. They function by improving access to basic services and supporting livelihoods,
97 thereby mitigating the consequences of financial shocks for those at risk of further impoverishment
98 (12,13). Examples include improving access to social services, assistance in the form of cash, food, or
99 transportation vouchers, training for participation in income-generating activities, community
100 administered savings groups, or training activities to encourage the development of human capital
101 (13,14).

102

103 Beyond protecting vulnerable groups from deepening poverty due to ill health, there has been mounting
104 interest in harnessing the benefits of social protection to achieve global TB elimination goals(15),
105 particularly in Africa(14). An emerging body of evidence demonstrates the utility and effectiveness of
106 social protection for improving TB outcomes including increasing uptake of TB services (16), reducing
107 risk of TB treatment default and improving rates of in TB treatment success and cure (13). Unfortunately,
108 how best to link TB affected populations to social protection programs in high HIV/TB burden, low-income
109 settings remains unknown. The landscape of social protection in Uganda, exemplary of this context,
110 includes a number of government-supported programs but none that include a mechanism to enroll
111 potentially eligible individuals affected by TB (so-called “TB-sensitive” programs), nor any social
112 protection programs that target TB patients specifically (so-called “TB-specific” programs) (**S1 Table**)(17).
113 Limited evidence exists on how to design such programs in accordance with TB elimination strategies
114 (9,18). This gap presents a major operational and programmatic barrier for implementing social and
115 economic supports for TB affected populations(19,20). To address this gap, we implemented and
116 evaluated the feasibility of a health center (HC)-based social protection linkage strategy for individuals
117 presumed to have TB in Uganda.

118

119 **METHODS**

120 **Study setting and population**

121 In partnership with the Ministry of Health (MoH) and the Ministry of Gender, Labour and Social
122 Development (MoGLSD) of Uganda, we piloted a program to link eligible adults seeking TB diagnostic
123 evaluation services from four community HCs with existing government-supported social protection
124 programs in Uganda (May to December 2021). Participating HCs were classified as Level IV HCs, where
125 TB diagnosis and treatment services are offered and are managed by the National Tuberculosis and

126 Leprosy Programme (NTLP) within the MoH. Participating community development offices (CDO, n=10)
127 served the same catchment area as participating HCs. CDOs are under the purview of the MoGLSD and
128 are responsible for the local administration of government-supported social protection programs including
129 disseminating information on existing social services locally, screening and enrolment for eligible
130 individuals, and distributing benefits.

131

132 **Eligibility criteria and study population**

133 The study population included all individuals ≥ 18 years of age being evaluated for TB at a participating
134 HC, defined as having submitted a sputum sample to the laboratory for TB diagnostic evaluation. After
135 submission of their sputum sample, health center staff asked adults three questions to screen them for
136 eligibility into any one of the seven major government-supported social protection programs included in
137 our pilot program. This included verification that the individual: 1) lives in a participating subcounty served
138 by one of the included CDOs; 2) is not a salaried government worker; and 3) does not already receive
139 benefits from a government-supported social protection program.

140

141 **Procedures**

142 **Social protection program identification**

143 With key stakeholders including MoGLSD and NTLP, we landscaped the social development sector to
144 identify active government-supported social protection programs being implemented across all regions
145 where the pilot was taking place. We collected data on each social protection program according to target
146 population, eligibility criteria, benefit scheme and structure, geographic catchment area, and duration of
147 program implementation.

148

149 **Facilitated linkage process**

150 Procedures for social protection program facilitated linkage include steps for screening, eligibility
151 determination, and provision of a transportation voucher and referral documentation for eligible adults to
152 present to the local CDO. Research study staff introduced linkage procedures to each participating HC
153 and subcounty CDO and conducted trainings with relevant personnel. At each HC, the village health
154 team (VHT) worker responsible for screening HC clients for TB was identified to serve as the focal point
155 for study activities. The VHT assessed all persons under evaluation for TB for eligibility for government-
156 supported social protection programs and informed each person whether they were likely eligible for a
157 social protection program based on results of the screening. Those likely eligible for social protection
158 program enrollment were asked about their interest in referral; those interested were given: 1) a referral
159 slip with a unique identifier to present to the CDO officer with sociodemographic and eligibility information,
160 and 2) instructions on how to access the respective subcounty CDO to seek social protection program
161 enrollment. VHTs also informed all participants that they would receive a one-time transport voucher of
162 20,000 Ugandan Shillings (USH; ~\$5.64USD) after they presented to the CDO. At the CDO, the
163 development officer received the participants with the referral slip bearing their unique identifier,
164 registered them in a study screening and enrollment logbook, and then followed routine procedures for
165 enrolling community members into government-supported social protection schemes including providing
166 information on available schemes and prerequisites for enrolment. At the CDO, participants found eligible
167 for one or more schemes were enrolled as per the discretion of the development officer and according to
168 their standard operating procedures.

169

170 **Data collection**

171 **Social protection referral data collection**

172 Process metrics were abstracted from logbooks at each HC and CDO to assess implementation and
173 enrollment outcomes (see **Outcomes**). Focal persons at each HC and CDO was identified and trained
174 using a camera-enabled smartphone to take photos of the HC and CDO logbooks, respectively. They

175 would then upload the photos to a central secure server using the National Institutes of Health (NIH)-
176 recommended Research Electronic Data Capture (REDCap) software mobile application (21).

177

178 **TB clinical data collection**

179 Full data abstraction procedures are standardized for TB diagnostic evaluation studies within the Uganda
180 Tuberculosis Implementation Research Consortium (U-TIRC), and are described elsewhere (22). In brief,
181 data were collected at all HCs from NTLP Presumptive TB registers, Laboratory and Treatment registers,
182 and Xpert laboratory requisition forms. These data included key patient demographic and clinical
183 (including HIV-related) information in addition to TB outcomes. Data quality assurance is as described
184 previously (22). Research staff matched social protection referral data to TB register data using
185 participant identifiers such as name and referral dates to create a linked study database which was
186 subsequently de-identified.

187

188 **Survey data collection**

189 The VHT also assessed those found to be eligible for government-supported social protection programs
190 for interest in survey participation. We randomly selected a subset of those interested for survey
191 participation, stratified by HC and sex. We collected socioeconomic information as well as perceptions
192 and experiences with linkage to the CDO for social protection enrollment. Surveys were conducted one
193 month following HC referral.

194

195 **Outcomes**

196 Study outcomes focused on implementation outcomes that reflected the HC screening and linkage
197 process. These outcomes included numbers and proportions of: 1) people with presumed TB screened
198 for eligibility for study and social protection linkage criteria at the HC (screened), 2) those eligible for
199 linkage among total screened (eligible), 3) those referred to the CDO among those eligible (referred), 4)

200 those who presented to the CDO after referral (linked), 5) those sent the 20,000 USH transport
201 reimbursement, and 6) those ultimately enrolled into a social protection scheme (enrolled). Among those
202 who presented to the CDO we ascertained time from referral to presentation for social protection
203 enrollment. We additionally included TB care outcomes related to TB screening, diagnosis, and
204 treatment.

205

206 **Statistical analysis**

207 We assessed patient characteristics, implementation of the pilot linkage process, TB register data, and
208 survey results using numbers and proportions for categorical data and either median and interquartile
209 ranges (IQR) or means with standard deviations (SD) for continuous variables. All analyses were
210 conducted using Stata version 16 (StataCorp, TX USA).

211

212 The study protocol was approved by the institutional review boards of the University of California San
213 Francisco, San Francisco, CA, USA, Makerere University School of Public Health, Kampala, Uganda and
214 by the Uganda National Council for Science and Technology, Kampala, Uganda, and included a waiver
215 of written informed consent for social protection program referral and access to routinely collected
216 demographic and clinical information among all participants. Verbal consent was obtained for
217 participation in surveys.

218

219 **RESULTS**

220 **Social protection program characteristics**

221 We identified seven major government-supported social protection programs being implemented across
222 all regions where the pilot was taking place. A description of the target population and intended function
223 and structure of benefits and geographic coverage are summarized in **S1 Table**. All programs provide

224 benefits at either the subcounty or parish level, which is the most granular administrative level in a sub-
225 county. The majority of social protection programs were group-based, in which benefits are distributed
226 not individually, but to a group of eligible individuals participating in the same enterprise. Most social
227 protection programs provided benefits as loan requiring repayment with interest. Two programs
228 distributed benefits as grants, which do not require repayment, and one program distributed agricultural
229 inputs to land-owning beneficiaries.

230

231 **Feasibility of the pilot facilitated linkage process**

232 From May to December 2021, we screened 855 persons undergoing TB diagnostic evaluation at
233 participating HCs. Among the 855 screened, we found 655 (76%) adults to be eligible per government-
234 supported social protection program criteria. 25 (4%) of those eligible were not interested in referral and
235 declined to participate. The remaining 630 (96%) were informed they were likely eligible for a social
236 protection program based on results of the screening. All were referred to the CDO for further
237 assessment. Sociodemographic and clinical information on participants referred for social protection
238 enrollment is shown in **Table 1**. 386 (61%) of those referred were successfully linked to the sub-county
239 CDOs and were ultimately evaluated for social protection program enrollment with a median time to
240 linkage of 1 day (IQR: 0-4). The development officer at the CDO found 382 of the 386 (99%) participants
241 referred for social protection enrollment to be eligible for one or more government-supported social
242 protection program. Of the 386 total participants linked to the CDO, 362 (94%) received the transport
243 refund. 122 (32%) of those who were linked and evaluated at the CDO were ultimately enrolled into a
244 social protection scheme, representing only 19% of those eligible (**Fig 1**). There was substantial variation
245 in implementation outcomes by health center (**S2 Table**).

246

247 **Table 1. Demographic and clinical characteristics of the study population across all participating**
248 **health centers.**

Characteristic	N (%) or Median (IQR)
Age, Median (IQR)	35 (26-48)
Female sex, n (%)	372 (59.0)
HIV status, n (%)	
Positive	170 (27.0)
Negative	441 (70.0)
Unknown	19 (3.0)
Micro-bacteriologically confirmed TB, n (%)	36 (5.7)
Treated, n (%)	30 (4.8)
Treatment outcome (n=30), n (%)	
Completed	15 (42.1)
Cured	10 (33.3)
Lost to follow up	1 (3.3)
Died	3 (10.0)
Transferred out	1 (3.3)

249 CDO=community development office; IQR=interquartile range; TB=tuberculosis

250

251 **Fig 1. Linkage feasibility based on cascade of screening, referral, and enrolment into a social**
252 **protection program.** CDO=community development office; SP=social protection. Each bar represents
253 a necessary step in the linkage program from screening for social protection enrolment, identification of
254 those eligible, facilitated referral for those interested in participating, linkage to the CDO, and enrolment
255 in an available program. Reasons participants were found to be ineligible for social protection eligibility
256 included those living in a subcounty outside of the jurisdiction of the CDO (n=134; 16% of all screened),
257 those not meeting age requirements (n=38; 4% of all screened), those who were government workers on
258 payroll (n=14; 2% of all screened), and those already enrolled in social protection schemes (n=14; 2% of
259 all screened).

260

261 **Survey results**

262 Ninety-seven participants (median age was 38 years (IQR: 26-48); 57 (59%) were female) responded to
 263 our survey. Over half (n=49; 51%) of the participants were multidimensionally impoverished or severely
 264 multidimensionally impoverished based on the Multidimensional Poverty Index (MPI) (22). Dissaving due
 265 to the economic impact of TB was common; 74% (n=72) used personal or household savings, 51% (n=50)
 266 reduced household food intake, 41% (n=40) sold an asset, and 40% (n=39) took out a loan to cover costs
 267 associated with their current episode of illness (**Table 2**). Unmet social needs were also commonly
 268 reported; 70% (n=68) of participants had food insecurity, 39% (n=38) lacked reliable transport to the HC,
 269 and 80 participants (82%) indicated that it was difficult to pay or find basic needs such as food, housing,
 270 and medical care (**Table 3**).

271

272 **Table 2. Household and individual characteristics of survey participants.**

	N (%), Mean (SD), or Median (IQR)
Total surveys	97
Age (Median, IQR)	38 (26-48)
Female sex	57 (58.8)
Multidimensional Poverty Index	
Not poor/not vulnerable	17 (17.5)
Vulnerable to poverty	31 (32.0)
Impoverished	34 (35.1)
Severely impoverished	15 (15.5)
Participant is head of household	62 (63.9)
Participant is not currently working	19 (19.6)
Education level	
None	6 (6.2)
Primary level	62 (63.9)
Secondary level	25 (25.8)

Tertiary level	4 (4.1)
Household size (Mean, SD)	5.8 (2.9)
Participant has a functional bank account	19 (19.6)

273 IQR=interquartile range; SD=standard deviation

274

275 We compared self-reported data regarding social protection program referral, linkage and enrollment
 276 between HC and CDO logbooks. All survey participants (n=97) were found eligible for CDO referral.
 277 However, four survey participants did not realize they had been found eligible and were referred to the
 278 CDO for social protection enrollment. 64% (n=9/14) of those who thought they were enrolled into a
 279 scheme by the CDO had not been upon CDO logbook review, while 8 of those who were indeed enrolled
 280 into a social protection scheme according to CDO logbook data did not know that they had been enrolled.
 281 The majority (n=25; 54%) of those not enrolled into a program did not know the reason for why they were
 282 not enrolled (**Fig 1**). 63% (n=61) of survey participants indicated that they would have not sought out a
 283 social protection program without this linkage program.

284

285 **Table 3. Negative financial consequences and unmet social needs among individuals presumed**
 286 **to have TB (n=97).**

Economic impact of TB	N (%)
<i>Dissaving</i>	
Used personal or household savings	72 (74.2)
Reduced household food intake	50 (51.6)
Sold an asset	40 (41.2)
Took out a loan	39 (40.2)
Took a child out of school	7 (7.2)
<i>Unmet social needs</i>	
In past 1 month:	
Worried food would run out (sometimes/often)	68 (70.1)

Lack of reliable transportation kept from: health facilities, work, market, or from getting things needed for daily living 38 (39.2)

Been to a place where free food is distributed 14 (14.4)

Current living situation

Steady place to live 57 (58.8)

Steady place to live, but worried will lose it 37 (38.1)

No steady place to live 2 (2.1)

Missing living situation 1 (1.0)

Difficulty in paying/finding basic food/housing/medical care

Somewhat difficult 69 (71.1)

Not difficult at all 17 (17.5)

Very difficult 11 (11.3)

287 TB=tuberculosis. Participants in the pilot social protection linkage program randomly selected to
288 participant in a survey described persistent social and financial challenges during their illness.
289

290 **DISCUSSION**

291 Innovative, multisectoral approaches are urgently needed in order to reach the ambitious global public
292 health goal of ending TB. We sought to evaluate the acceptability and feasibility of a program in which
293 we facilitated the linkage of people with presumed TB from community health centers to local community
294 development offices for enrollment into government-supported social protection programs. Our results
295 suggest this linkage program was highly acceptable, with 92% of those eligible interested in the referral
296 program, as well as technically feasible, with 99% of participants linked from the HC subsequently
297 confirmed to be eligible for one or more government-supported social protection program. Our program
298 delivered transportation vouchers with high fidelity; 94% of those who sought social protection enrolment
299 at the CDO successfully received their mobile money. Our results also suggest that this social protection
300 linkage program addressed an important need: 63% of surveyed participants (n=61) felt that the program
301 facilitated access to social protection benefits that they might otherwise not have sought out. Despite

302 feasibility and acceptability of this health system-based linkage process, ultimate enrollment into
303 programs was limited. Among the 382 total eligible persons linked to CDOs, only 122 were enrolled into
304 a program, representing less than 20% (n=655) of those who were eligible to receive social protection
305 benefits.

306

307 Our study demonstrates individuals with presumed TB are exceedingly socioeconomically vulnerable,
308 with high levels of impoverishment and unmet social needs. Over half of our participants were classified
309 as either impoverished or severely impoverished based on a validated quantitative measure, the MPI.
310 Surveys revealed many participants engaged in negative financial coping strategies, called dissaving, in
311 order manage the costs of TB associated care seeking and symptoms: 40% of participants took out a
312 loan, 41% sold an asset, 52% reduced household food intake, and 74% used personal or household
313 savings (**Table 3**). Most surveyed participants reported unmet social needs, including 82% who indicated
314 they faced difficulties in accessing basic needs and services including food, housing, and medical care.
315 In the month prior to participating in our surveys, over 70% of participants were worried that their food
316 source would run out, with 14% of respondents having been to a place where free food is distributed.
317 These results are in keeping with the large literature citing the social and economic consequences of TB
318 (3,6,23). Unfortunately, while 76% of individuals being evaluated for TB related symptoms were eligible
319 for social protection programs, less than 20% were enrolled, representing a major gap in social protection
320 service delivery for this vulnerable population.

321

322 Several implementation challenges likely contributed to the substantial attrition of participants from the
323 time of referral at the health center to social protection program enrolment. Distance between the HC and
324 CDO and/or associated time and opportunity costs for additional visits to a government office may not
325 have been overcome by our transportation vouchers for all participants. Among those that reached the
326 CDO but were not enrolled in a social protection program, attrition was largely due to unpredictable
327 closures at the CDO and a lack of available development staff. Even after linkage to a development office,

328 our survey results revealed that 20% of eligible participants faced systems barriers to enrollment,
329 including strict limitations to enrollment based on the terms and structure of government-supported
330 programs. In most Ugandan social protection or development programs, eligible clients are required to
331 either form or join groups of 7 or more other eligible clients prior to being enrolled. Although requirement
332 for group formation is likely intended to mitigate financial risk for the program and support community
333 building, it presented a formidable barrier to enrollment for our study participants who are often left to
334 navigate these complex terms on their own. Finally, we found evidence of knowledge and communication
335 barriers among participants. Over half of survey participants indicated that they were not told the reason
336 for why they were not enrolled into a social protection program. Other discrepancies were also noted: 8
337 survey participants whose logbook data reflected social protection program enrollment reported that they
338 were not enrolled, while 9 participants self-reported that they were enrolled into a program when logbook
339 data indicated that they were not. This mismatch may reflect a breakdown in communication and lack of
340 understanding among community members of the process of receiving social protection benefits. These
341 results also highlight the importance of optimizing performance for social protection programs as a pre-
342 requisite for successful implementation and scale up of sustainable multi-sectoral linkage programs that
343 address the social and economic determinants of TB.

344

345 As with most pilot programs, our approach has several potential limitations. First, we did not include
346 informal, community-based social protection programs that are common in Uganda, including saving
347 circles or loans from faith-based organizations, nor did we include large social protection programs
348 administered and funded by multilateral or bilateral implementing partners in our linkage program. We
349 chose not to include these programs as they were not government funded and thus had less likelihood
350 for sustainable scale-up. Future research may consider the impact that access to such programs may
351 have on TB outcomes. Additionally, we observed high levels of heterogeneity in screening, eligibility, and
352 enrollment across participating HCs (**S2 Table**) but were unable to explain the reason behind these
353 differences with our study data alone. Additional research including interviews with health center staff

354 and CDO officers will be necessary to gain a better understanding for the differences we saw in program
355 eligibility and enrollment across health centers, as well as the supply and demand mismatch we observed
356 in access to social protection programs for eligible TB-affected individuals overall.

357

358 The main strength of our study stems from our early partnership and collaboration with both the
359 NTLP/Ministry of Health and the Expanded Social Protection Programme within the MoGLSD. Engaging
360 a key governmental partner outside of the health sector with the mandate for provision of social protection
361 programs enabled our study to co-design our implementation strategy, collect essential process metrics,
362 and leverage ongoing programs in our approach. Our focus on implementation outcomes provides a
363 simple and systematic approach to measure social protection program coverage and attrition in services
364 for eligible TB-affected individuals which may be replicated in other similar settings. Finally, our use of
365 explanatory surveys provides some crucial insights into key gaps in the linkage process, while also
366 highlighting barriers and facilitators that will support the development of improved linkage strategies and
367 metrics to foster multisectoral accountability, an approach highlighted as critical for reaching END TB
368 targets (20).

369

370 While all government-supported social protection programs that were included in this study could be
371 considered TB-sensitive, in that although not directly targeting TB-affected patients their effects could
372 have downstream impacts on TB-related outcomes and mitigate the financial consequences of disease
373 (19), the challenges with even facilitated linkage to such programs suggests that an improved strategy
374 for reaching vulnerable TB affected individuals is required. Like other high-burden and low-income
375 countries, no government-supported social protection programs are available to Ugandans with TB
376 specifically on the basis of their TB status. Given the recent growing interest in the use of social protection
377 and other multisectoral approaches to improve outcomes for TB-affected households in Uganda (20) and
378 in other similar contexts (13,24), policy makers and stakeholders should consider collaborating to improve

379 program performance for those eligible and/or expanding the types of social development and social
380 protection programs available for individuals and households affected by TB.

381

382 **CONCLUSIONS**

383 Individuals at risk for TB in this high-burden, low-income setting are extremely socioeconomically
384 vulnerable and, unfortunately, not covered by government-supported social protection programs despite
385 eligibility and interest. A health center based social protection linkage program for individuals presumed
386 to have TB, in partnership with community development offices, while acceptable and technically feasible,
387 has marginal impact due to implementation barriers to enrollment within the development sector.
388 Additional research is needed to identify optimal ways of enhancing access to essential social protections
389 for this vulnerable population.

404 **ACKNOWLEDGEMENTS**

405 The authors are grateful to the administration, staff, and patients at the participating health centers for
406 their time and participation, the staff and administration for the participating community development
407 offices, the research administration of the Uganda TB Implementation Research Consortium, the
408 Expanded Social Protection Programme within the Ministry of Labour, Gender, and Social Development,
409 and the National Tuberculosis and Leprosy Program.
