21 Abstract

Background: The advantages of urban areas for patients with out-of-hospital cardiac arrest
(OHCA), attributable to their extensive medical resources, are well recognized. However,
whether a greater abundance of these resources directly improves patient outcomes is unclear.
Moreover, it is important to clarify this because of the ongoing global trend of urbanization.
Therefore, this study aimed to investigate this issue and shed light on the potential challenges
specific to urban environments.

28 **Methods:** This retrospective observational study was conducted to evaluate the correlation 29 between the geographical features of patients with shockable OHCA and neurological 30 outcomes. Data of patients who were transported to Tokyo Medical and Dental University 31 Hospital between June 1, 2016, and May 30, 2022, were extracted from electronic review 32 board records. The Glasgow-Pittsburgh Cerebral Performance Category Scale was utilized to 33 evaluate the neurological results. The study employed Bayesian spatial modeling and 34 analyzed the results using the Integrated Nested Laplace Approximation and Stochastic 35 Partial Differential Equation methods. **Results:** Paradoxically, a region with the highest concentration of advanced medical facilities 36 37 exhibited the poorest neurological outcomes. This area was characterized by an extended duration of on-site emergency medical service activity, which strongly correlated with a 38 39 negative impact on patients' neurological outcomes. 40 **Conclusions:** The abundance of healthcare resources in urban areas does not necessarily 41 correlate with improved outcomes for patients with OHCA. A strategic approach to medical 42 control that considers these factors can potentially enhance the outcomes of patients with OHCA in urban areas. 43

- 54 OHCA: out-of-hospital cardiac arrest
- 55 SPDE: Stochastic Partial Differential Equation
- 56 TMDU: Tokyo Medical and Dental University Hospital

69 Clinical Perspectives

70 What is new?

- 71 In a retrospective geographical analysis of patients with shockable Out-of-Hospital Cardiac
- 72 Arrest (OHCA), it was found that the region with the highest concentration of advanced
- 73 medical facilities paradoxically exhibited the poorest neurological outcomes. Additionally,
- there was a noticeable extension in the duration of on-site emergency medical service activity

75 in this area.

76 What are the clinical implications?

- 77 The abundance of healthcare resources in urban areas does not necessarily equate to
- 78 improved outcomes for patients with OHCA. Therefore, a strategic approach to medical

resource management should be considered to effectively utilize these resources and enhance

80 the outcomes of patients in urban areas.

83 Introduction

Despite advancements in emergency medicine, the survival rate and neurological outcomes 84 for out-of-hospital cardiac arrest (OHCA) are suboptimal.^{1,2} The prognosis for OHCA is 85 influenced by various factors, including age,³ sex,⁴ and comorbidities.⁵ Prompt action by 86 bystanders and emergency medical services (EMS),⁶⁻⁹ coupled with comprehensive hospital 87 treatment, can enhance neurological outcomes.^{10,11} Furthermore, spatial factors such as 88 population density¹² and rural–urban differences^{6,13} significantly affect the prognosis of 89 90 OHCA. These findings highlight the advantages of urban environments, primarily due to the 91 availability and accessibility of extensive medical resources.

92 There are trends of urbanization worldwide, and it is presumed that nearly 10 billion people are projected to live in urban areas by 2050.^{14,15} Tokyo, one of the world's most 93 densely populated urban areas.¹⁶ has over 250 active EMS units and more than 10 tertiary 94 emergency hospitals, specializing in treating life-threatening conditions.¹⁷ This level of 95 96 preparedness makes Tokyo a prime exemplar of urban readiness for OHCA incidents. Previous studies have demonstrated the advantage of urban areas over rural areas.^{6,13,18–20} 97 However, there is no previous study that evaluated the association between OHCA prognosis 98 99 and geographical factors in urban settings, and it remains unclear whether the greatest 100 abundance of these resources in city centers will lead to the best patient outcomes. Therefore, 101 this study aimed to elucidate the correlation between the prognosis of OHCA and 102 geographical factors in urban settings, a challenge that is poised to become a global concern.

103 Methods

104 Study design and setting

105 This retrospective observational study aimed to evaluate the correlation between geographical 106 features and the prognosis of patients with OHCA exhibiting a shockable rhythm who were 107 transported to Tokyo Medical and Dental University Hospital (TMDU) between June 1, 2016 108 and May 30, 2022. TMDU is a tertiary hospital located in the heart of Tokyo, in close 109 proximity to the Imperial Palace, Tokyo Station, and central government offices. In Tokyo's 110 emergency system, hospitals are classified into three distinct levels based on the projected severity of the patient's condition.²¹ TMDU, as a tertiary hospital, specializes in treating 111 112 severe, life-threatening conditions, and as such, patients with OHCA are typically directed 113 there.

This research followed the guidelines outlined in the 1964 Declaration of Helsinki and its subsequent revisions, and received approval from the Institutional Review Board of TMDU (#M2022-117). Given the retrospective design of the study and use of anonymized patient and hospital data, the requirement for informed consent from patients was waived.

118 Study populations

This study enrolled patients with OHCA who exhibited shockable rhythm (ventricular tachycardia or ventricular fibrillation) on the arrival of the EMS team and were in a state of cardiopulmonary arrest on hospital arrival. The study excluded patients aged <18 years and those with existing "do not attempt to resuscitate" (DNAR) orders.</p>

123 Data collection

124 The data for this study were obtained retrospectively collected from the medical records of

- the patients: age, sex, Glasgow–Pittsburgh Cerebral Performance Category (CPC) scale score
- 126 30 days after hospital admission, EMS time-related details (time of EMS request, EMS

arrival, on-site departure, and hospital arrival), and EMS geographical data (name ofbuilding, town, street, and address).

129 Outcomes and definitions

- 130 The primary analysis involved the geographical assessment of neurological outcomes.
- 131 Additional evaluations of the EMS on-scene response time (the duration from the EMS
- team's arrival at the scene to departure) and transport time (the duration from departure from
- the scene to arrival at the emergency department) were performed. Neurological outcomes
- 134 were assessed using the CPC scale. A score of CPC 1 signifies consciousness with normal
- function or only slight disability, CPC 2 represents consciousness with moderate disability,
- 136 CPC 3 indicates consciousness with severe disability, CPC 4 denotes coma or vegetative
- 137 state, and CPC 5 stands for death.²² For the analysis, patients were divided into those with
- 138 CPC 1 or 2 (signifying good neurological outcomes) and those with CPC 3, 4, or 5
- 139 (indicating poor neurological outcomes).

140 Statistical analysis

141 Bayesian spatial model

- 142 We assumed that there is a possibility of good neurological outcome $P(x_i)$ at each data point
- 143 x_i . By denoting the number of people N_i at location x_i , the number of people with good
- 144 neurological outcomes (CPC 1 or 2) Y_i follows the distribution:

 $Y_i | P(x_i) \sim Binomial(N_i, P(x_i)) \#(1)$

145 $P(x_i)$ at each location is modeled through the logit link function:

 $logit(P(x_i)) = \beta_0 + D\beta + \xi(x_i)\#(2)$

146 β_0 denotes the intercept. Age and sex in each sample location were analyzed as covariates in 147 the model and defined $\beta = (\beta_{age}, \beta_{sex})$ a vector of the covariate coefficients. *D* is a design 148 matrix with rows corresponding to the covariate data for each sample location. Here, $\xi(x)$ is 149 a zero-mean Gaussian process with a Matérn covariance function²³ as follows:

$$Cov(\xi(x_i),\xi(x_j)) = Cov(\xi_i,\xi_j) = \frac{\sigma^2}{2^{\lambda-1}\Gamma(\lambda)} \left(\kappa \left| \left| x_i - x_j \right| \right| \right)^{\lambda} K_{\lambda} \left(\kappa \left| \left| x_i - x_j \right| \right| \right) \#(3)$$

150 $||x_i - x_j||$: Euclidean distance between locations x_i, x_j, σ^2 :marginal variance.

151 K_{λ} is the modified Bessel function of second kind, order $\lambda (> 0)$: smoothness parameter,

152 $\kappa(> 0)$: scaling parameter related to the spatial correlation range.

153 Stochastic Partial Differential Equation approach

- 154 The Stochastic Partial Differential Equation (SPDE) approach enables approximation of a
- 155 continuous process using discrete random process.²⁴ SPDE can be written as

$$(\kappa^2 - \Delta)^{\alpha/2}(\tau\xi(x)) = \mathcal{W}(x)\#(4)$$

156 Where $s \in \mathbb{R}^d$, Δ : Laplacian, α : smoothness parameter, κ : scale parameter, τ : variance,

157 $\mathcal{W}(s)$: Gaussian spatial white noise process. This solution can be given by the Matérn

158 covariance equation (3) and can be approximated using the finite element method, which can

159 be represented by

$$\xi(x) = \sum_{g=1}^{G} \varphi_g(x) \widetilde{\xi_g} \, \#(5)$$

160 G: total number of vertices of triangulation, φ_g : basis functions, $\tilde{\xi}_g$: zero-mean Gaussian-161 distributed weights.

162 Bayesian inference using Integrated Nested Laplace Approximation

The Bayesian inference was performed using Integrated Nested Laplace Approximation
(INLA).²⁵ The marginal posteriors of parameters z = (β₀, β, ξ), and the hyper-parameters θ,
can be represented by the following equation,

$$p(z|y) = \int p(z|\theta, y) \, p(\theta|y) \, d\theta \ \#(6)$$

In the INLA approach, the integrand is approximated using the Laplace
 approximation, and numerical integration is performed. A detailed description is written
 elsewhere.²⁶

169 Gaussian Process Regression between temporal information and neurological outcomes

- 170 Gaussian Process Regressions²⁷ were conducted to elucidate the correlation between EMS
- 171 on-scene response time and neurological outcomes and between transport time and
- neurological outcomes. The models were almost identical to equations (1) and (2); however,
- in this analysis, geographical information x_i was substituted with temporal information t_i .

 $Y_i | P(t_i) \sim Binomial(N_i, P(t_i)) \#(7)$

 $logit(P(t_i)) = \zeta(t_i) \#(8)$

174 $\zeta(t)$ is a Gaussian process with Gaussian kernel:²³

175
$$k(t_i, t_j) = exp(-\beta ||t_i - t_j||^2) \#(9)$$

176 Software

177 The statistical analyses were conducted using R software (version 4.1.2; R Foundation for

178 Statistical Computing, Vienna, Austria). Geospatial analyses were conducted using R-INLA

- (version 18.07.12). Google Maps Platform (<u>https://mapsplatform.google.com/</u>) was used to
 display the analyzed geographic information.
- 181

182 **Results**

183 A total of 835 patients with OHCA were identified during the study period. Of these, 110

184 exhibited shockable rhythms on arrival of the EMS team. None of the patients was under the

age of 18 years, and none had existing DNAR orders. Table 1 presents the demographic

186 characteristics of the patients. The distribution of the 30-day CPC scores was as follows: CPC

- 187 1–18 (16.4%), CPC 2–16 (14.5%), CPC 3–14 (12.7%), CPC 4–12 (10.9%), and CPC 5–56
- 188 (50.9%).
- 189 Neurological prognosis in relation to geographical features

190 The neurological outcomes of patients with OHCA and their correlation with geographical

191 factors are presented in Figure 1 (figures without annotations are provided in Figure S1).

192 Overall, there was a trend toward an improved neurological prognosis with increasing

193 proximity to TMDU. However, it is noteworthy that despite being close to TMDU (2–8 km

- 194 northeast of TMDU) and other tertiary hospitals, the region exhibited poor neurological
- 195 outcomes (the area within the dotted line).

196 *Geographical differences in EMS on-scene response time and transport time*

197 Geographical variations in the on-scene response time and transport time are depicted in

198 Figure 2A and 2B, respectively. Figure 2B reveals a roughly positive correlation between the

- 199 hospital's distance and transport duration, with longer transport times associated with more
- 200 distant locations. Figure 2A demonstrates the prolonged on-scene response times (median

18.0 min [25th–75th percentiles: 13.5–25.0 min]) within the area delineated by the dotted
line in Figure 1.

203 Correlation between EMS on-scene response time/transport time and neurological outcomes

Figure 3A, B shows the correlations between on-scene response time and neurological prognosis and between transport time and neurological prognosis, respectively. Figure 3A illustrates that an increase in on-scene response time from 0 to 30 minutes results in a 50% decrease in patients with favorable neurological outcomes. Similarly, Figure 3B reveals that extending the transport time from 0 to 15 minutes leads to a 25% decrease in the percentage of patients with favorable outcomes. Both outcomes suggested that a longer duration was correlated with a worse prognosis. Notably, the on-scene response time appeared to have a

210 conclated with a worse prognosis. Notably, the on-seene response time appeared to have a

211 more significant impact on neurological outcomes than the extended transport time.

212

213 **Discussion**

214 Previous studies have demonstrated a positive correlation between the degree of urbanization 215 and the prognosis of patients with OHCA. These studies have generally compared urban areas with rural and/or suburban areas.^{6,13,18–20} However, to our knowledge, this is the first 216 217 study that specifically investigates the regional variations within the urban areas themselves. 218 We observed an area with a high concentration of advanced medical facilities that paradoxically demonstrated poor neurological outcomes. This area exhibited a longer 219 220 duration of on-site EMS activity, which had a substantial negative impact on neurological outcomes. 221

Although most existing literature focuses on assessing mortality, the current study was designed to evaluate the neurological prognosis. This approach aims to mitigate perceived arbitrariness: a significant number of patients with poor neurological outcomes are faced with the decision to withdraw treatment.²⁸ Moreover, we confined our study to OHCA cases involving patients who presented with shockable rhythms. This limitation was implemented because the initial rhythm poses a substantial confounder,²⁹ which could influence the correlation between geographical features and patient prognosis even with adjustments.

230 In Tokyo's emergency system, the selection of hospitals is made by sequentially 231 contacting the facilities, starting from those nearest to the patient's location, until a 232 destination hospital is determined. Tertiary hospitals are densely situated in central Tokyo, 233 with TMDU notably surrounded by these hospitals (Figure 1). Therefore, most OHCA cases 234 in TMDU comprise patients who cannot be accommodated by other facilities. Another 235 unique aspect of Tokyo's emergency system is that EMS teams are rarely authorized to 236 conduct basic life support. Certain EMS teams have the permission to place an adjunct 237 airway, operate a semi-automated external defibrillator, and insert an intravenous line, but all 238 these treatments are only authorized under the telephonic guidance of a doctor, with no other actions being permitted.^{30,31} 239

Prior research suggests that extended transport time does not adversely affect 240 survival rates or neurological outcomes.³² The consensus is that, despite prolonged transport 241 times, the patient benefits from being transported to a high-level medical facility.³³ The 242 243 findings of the current study may seem to contradict this, but they can be better understood 244 by considering two key points. First, this was a single-center investigation; hence, the type of 245 medical institution did not act as a confounding variable between transport time and 246 prognosis. Second, given the limitations of the resuscitation procedures that EMS teams in 247 Japan can execute, extended transport times can lead to delays in the provision of advanced 248 cardiovascular life support.

The prolongation of on-scene time negatively affects patient outcomes, which aligns with the findings of a previous study.³⁴ Interestingly, extending the time on the scene appears to have a more detrimental impact on patient outcomes than the lengthening of transport time. This may be due to the fact that once the destination is determined, the hospital can prepare for the patient's arrival, thereby making more efficient use of the transport time compared to the time spent on-scene.

255 This study has several limitations. First, although adjustments for confounders such as 256 age and sex were made, the potential for unobserved and residual confounding factors could 257 not be eliminated. Second, because this was a single-center study, we might not have 258 captured geographical features that might only become apparent when collating data from 259 multiple facilities. Third, our study was limited to patients with OHCA presenting with 260 shockable rhythms. Therefore, our findings might not be generalizable to all patients with 261 OHCA. Despite these limitations, our study is the first to focus on the demographics of 262 patients with OHCA in urban medical systems. Poor neurological outcomes were apparent in 263 areas with the most abundant medical systems. Based on the results of this study, it may be 264 important to consider strategies that can effectively utilize abundant medical resources, such 265 as pre-arranging the destination for patients with OHCA to avoid delays in transportation.

- https://www.jmaj.jp/detail.php?id=10.31662%2Fjmaj.2020-0074. JMA Journal.
 2021;4:8–16.
- 32. Geri G, Gilgan J, Wu W, Vijendira S, Ziegler C, Drennan IR, Morrison L, Lin S. Does
 transport time of out-of-hospital cardiac arrest patients matter? A systematic review and
 meta-analysis. *Resuscitation*. 2017;115:96–101.
- 393 33. Cha WC, Cho JS, Shin SD, Lee EJ, Ro YS. The impact of prolonged boarding of
- successfully resuscitated out-of-hospital cardiac arrest patients on survival-to-discharge
 rates. *Resuscitation*. 2015;90:25–29.

- 396 34. de Graaf C, Beesems SG, Koster RW. Time of on-scene resuscitation in out of-hospital
- 397 cardiac arrest patients transported without return of spontaneous circulation.
- *Resuscitation*. 2019;138:235–242.

Patient Characteristics

Sex, Female, n(%)	17 (15.5)
Age, median (25th–75th percentiles)	62 [52–74]
Presence of witness, n(%)	81 (73.6)
Bystander CPR, n(%)	69 (62.7)
Distance from TMDU (km), median [25th-75th percentiles]	19.3 [12.0–29.8]
Time from call receipt to the arrival of the vehicle at the scene (min),	6 [5-8]
median [25th–75th percentiles]	
Time from the vehicle's arrival at the scene to the departure from the	16 [12–20]
scene(min), median [25th-75th percentiles]	
Time from departure from the scene to the arrival to arrival at the ED	7 [5.25–12]
(min), median [25th-75th percentiles]	

Location of cardiac arrest, n(%)

Home	28 (25.5)
Road	23 (20.9)
Station	15 (13.6)
Office	6 (5.5)
Clinic	6 (5.5)
Hotel	2 (1.8)
Shop	4 (3.6)

- 400 Table 1: Patient demographics
- 401 Abbreviations: CPR: cardiopulmonary resuscitation, ED: emergency department, TMDU:
- 402 Tokyo Medical and Dental University

403 Figure legends

404 Figure 1: Neurological outcomes of patients with shockable rhythm out-of-hospital cardiac 405 arrest in relation to geographical factors. The red circle denotes the location of tertiary 406 medical centers, while the red triangle denotes the location of Tokyo Medical and Dental 407 University. The area within the dotted line marks the region where neurological outcomes 408 were poor despite its proximity to Tokyo Medical and Dental University. 409 Abbreviations: CPC: Glasgow–Pittsburgh Cerebral Performance Category. 410 411 Figure 2: The on-scene response time (the time from the vehicle's arrival at the scene to the 412 departure from the scene) in relation to geographical factors (A). The transfer time (the 413 duration from departure from the scene to arrival at the emergency department) in relation to 414 geographical factors (B). 415 416 Figure 3: The relation between the on-scene response time (the duration from the EMS) 417 team's arrival at the scene to departure) and neurological outcomes (A) and the relation

between transport time (the duration from departure from the scene to arrival at the

419 emergency department) and neurological outcomes (B).

Abbreviations: CPC: Glasgow–Pittsburgh Cerebral Performance Category; EMS: emergency
medical services
