21 **Abstract**

22 **Objective:** As an idiopathic hypertensive disorder of pregnancy, pre-eclampsia (PE)
23 remains a major cause of maternal and neonatal morbidity and mortality, with no
24 effective strategy for causal treatment.

25 **Methods:** This study was performed by downloading the Gene Expression Omnibus
26 (GEO) database (<http://www.ncbi.nlm.nih.gov/geo/>) based on the GSE173193 dataset,
27 including single-cell sequencing data from placental samples of two PE patients and
28 two normal controls. Placental cell subpopulations and their transcriptional
29 heterogeneity were compared between PE and healthy pregnancies, and the
30 mechanisms of PE cell dynamics in the hypoxic microenvironment were confirmed
31 by in vitro experiments.

32 **Results:** In this study, we constructed a large-scale single-cell transcriptome
33 ecological landscape of 26,416 cells from healthy pregnant and PE patients placenta
34 and further identified a PE-specific CSNK2B-positive subpopulation of chorionic
35 villous trophoblast (EVT) cells. Specifically, this study revealed that the EVT
36 subpopulation PTBP1 was inactivated by lactonization in the hypoxic
37 microenvironment, resulting in low expression of the N⁶-methyladenosine (m⁶A)
38 reading protein IGF2BP2. On the basis of this, low expression of IGF2BP2 inhibits
39 mitochondrial autophagy, causes the accumulation of damaged mitochondria,
40 exacerbates lactic acid accumulation while inducing EVT apoptosis on the one hand.
41 In particular, hypoxia may initially promote oxidative stress through the production of
42 mitochondrial reactive oxygen species. on the other hand, it inhibits EVT adherent
43 spot signaling, decreases EVT invasive ability, leads to impaired placental spiral
44 vessel recast, and promotes PE disease process. In addition, there are interactions
45 between abnormal metabolic signaling of PE-specific EVT subpopulations and
46 microenvironmental immune cells, which activate metabolic inflammation.

47 **Conclusion:** The present study not only provides a new cell biological and genetic
48 basis for elucidating the pathogenesis of PE, but also contributes to the design of an
49 allopathic treatment strategy for PE.

50 **Keywords:** single-cell transcriptomics, preeclampsia, chorionic trophoblast, hypoxia,
51 oxidative stress, mitochondrial autophagy

52 **Introduction**

53 Pre-eclampsia (PE) is a hypertensive disorder specific to pregnancy and a major
54 cause of maternal and neonatal morbidity and mortality (4%-5%), manifesting as
55 new-onset hypertension and proteinuria or end-organ damage after 20 weeks of
56 gestation (1-3). Globally, PE affects about 2-8% of pregnancies, killing about 76,000
57 pregnant women and 500,000 fetuses each year, and even causing up to 20% of
58 preterm birth events (4-6). However, as of today, PE remains incurable, with blood
59 pressure control being the main clinical intervention and placental delivery remaining
60 the only definitive treatment (7).

61 To date, the pathogenesis of PE is not fully understood, but abnormal placental
62 development plays an important role in the disease (8). During the early stages of
63 conception, trophoblast cells differentiate into cytotrophoblast cells (CTB) and
64 syncytial trophoblast cells (ST), followed by the formation of extravillous trophoblast
65 (EVT) from CTB. The EVT is able to invade the endometrium and remodel the uterine
66 spiral arteries to allow successful embryo implantation and development (9). In
67 addition, this process involves many cells at the maternal-fetal interface, including
68 some immune microenvironmental cells in addition to the trophoblast system
69 described above (10), which fully reflects the heterogeneous nature of placental cells.

70 Numerous studies have confirmed that hypoxia is closely associated with the
71 development of PE. decreased placental blood perfusion in the uterus of PE patients,

72 and the expression of hypoxia-related genes showed a striking correlation with the
73 placenta of PE patients, with consistent results in both in vivo and in vitro models of
74 placental hypoxia (11). The finding that rodent and primate models of uteroplacental
75 ischemia and hypoxia (12, 13) and a rat model of uteroplacental ischemia or
76 hypoperfusion (12) showed the same clinical signs as PE further confirms the
77 relevance of hypoxia to PE. Previous studies have demonstrated that early gestational
78 trophoblast cells produce large amounts of lactate through aerobic glycolysis at the
79 maternal-fetal interface and that moderate levels of lactonization can regulate redox
80 homeostasis and cell adhesion in the recipient endometrium to promote pregnancy.
81 however, abnormally elevated lactate due to a persistent hypoxic environment may be
82 detrimental to embryonic implantation (14, 15). As the oxygen receptor of cells,
83 hypoxia-inducible factor-1 (HIF-1) plays a major regulatory role in the hypoxic
84 environmental response, and HIF-1 activation in hypoxic environments can lead to
85 reprogramming of energy and nutrient metabolism (16). In contrast, in patients with
86 PE, HIF-1 activation causes CTB invasion dysfunction and incomplete helical artery
87 remodeling in the placenta, leading to excessive lactate accumulation (17, 18). All of
88 the above studies imply that lactate may play a crucial role in the microenvironment
89 of PE patients. Although the work of Yollyseth Medina et al. confirmed that CTB
90 hypoxia in PE patients activates anaerobic glycolysis leading to a functional defect in
91 lactate transport proteins, which in turn leads to excessive lactate accumulation and
92 promotes excessive protein lactation (19-21). However, the effect of hypoxia-induced
93 protein hyperlactation on PE has never been explored.

94 Furthermore, mitochondria are the major source of intracellular ROS in hypoxic
95 cells (22). Therefore, mitochondria play an important role in cell fate determination
96 under hypoxia, which is accompanied by increased production of reactive oxygen
97 species (ROS), causing oxidative stress (23), while excess ROS plays a role in cell
98 death key role (24).

99 A number of studies have examined extensive changes in the human placental
100 transcriptome (25, 26). Liu et al. performed single-cell RNA sequencing from human
101 placenta and identified novel subtypes of trophoblasts, Hofbauer cells, and
102 mesenchymal stromal cells (27, 28). Tsang et al. identified different cell subtypes in
103 human placenta by analyzing more over 24,000 cells, identified different cell subtypes
104 in the human placenta and reconstructed trophoblast differentiation trajectories (29).
105 In addition to this, proteomic assays have rapidly matured, and analysis of proteomics
106 can further yield complementary information combined with transcriptomic data to
107 enhance biomarker discovery (30). However, the changes that occur in various cell
108 types in placental tissues in the presence of hypoxia and the specific molecular
109 mechanisms are not known. Therefore, in this study, we analyzed single-cell
110 sequencing data to comprehensively characterize the molecular and cellular
111 physiopathological abnormal ecology of PE in the hypoxic microenvironment, while
112 combining single-cell transcriptome data with immunofluorescence, and proteomics
113 data to enable the elucidation of PE cellular dynamics mechanisms under complex
114 pathological conditions.

115 **Materials and Methods**

116 **Data sources**

117 The placenta is a highly heterogeneous organ that is closely associated with
118 adverse pregnancies. Previous bulk sequencing of whole tissues could not reveal the
119 characteristics of individual cells and cell-to-cell interactions. Here, we downloaded
120 the GSE173193 dataset based on the GPL24676 platform from the Gene Expression
121 Omnibus (GEO) database (<http://www.ncbi.nlm.nih.gov/geo/>), including single-cell
122 sequencing data from placental samples of two PE patients and two normal controls.
123 Sequencing data of placenta samples from the gestational diabetes mellitus group
124 (GDM) and the advanced age group (GL) were excluded from this study.

125 In addition, this study collected a total of 15 PE patients and 15 placental tissues
126 from a control donor. This study was approved by the Ethics Committee of The
127 Affiliated Yantai Yuhuangding Hospital of Qingdao University and written consent
128 was obtained from all patients or their legal guardians participating in the study.

129 **Cell lines and culture conditions**

130 HTR-8/SVneo (human immortalized EVT cell line) was purchased and cultured
131 in DMEM/F12 medium (GIBCO, USA), 10% inactivated fetal bovine serum (GIBCO)
132 and 1 % penicillin-streptomycin (GIBCO) at 37 °C and 5 % CO₂ until the logarithmic
133 growth phase of cells. Cells were inoculated onto six-well culture plates at a rate of 1
134 × 10⁵ cells/well and incubated in an incubator at 37 °C and 5 % CO₂. For various
135 experiments under hypoxic conditions, cells were cultured at 37 °C in a humid
136 chamber containing 2 % O₂ and 5 % CO₂ (Thermo, 3131, Waltham, Ma, USA).

137 **Tissue immunofluorescence**

138 PE patients and controls placenta (maternal side) tissue was embedded and
139 sectioned (6 μm thickness), then routinely dewaxed in xylene alcohol, repaired with
140 citric acid and then washed three times with distilled water for 3 min each. the
141 sections were closed with 1% Bovine serum albumin (BSA) for 30 min at room
142 temperature. the primary antibody was diluted with 1% BSA and incubated overnight
143 at 4 degrees. the next day, the sections were washed three times with phosphate buffer
144 solution (PBS) for 3 min each. then the sections were diluted with 1% BSA The
145 fluorescent secondary antibody was incubated for 1 h in a 37°C incubator with closed
146 light, and then the sections were washed three times with PBS for 3 min each time
147 under closed conditions. then the sections were blocked by adding glycerol-diluted
148 hoechst33342 (10 μg/ml) and photographed by laser confocal (Nikon, A1R+). For
149 fluorescent direct-labeled primary antibodies, fluorescently labeled primary antibodies
150 diluted with 1% BSA were added between washing away the secondary antibodies
151 and adding nucleation reagents, and then the sections were washed three times with
152 PBS for 3 min each time. in the case of non-fluorescently labeled secondary

153 antibodies with L-Lactyllysine, 488-labeled goat anti-rabbit secondary antibodies
154 were added after incubating the primary antibodies for another 30 min.

155 **IGF2BP2 mRNA in situ hybridization and immunofluorescence co-staining**

156 Cy3-tagged IGF2BP2 homo probe sequence:
157 CTTGCCACCT+TTGCCAATCACCCG. RNA in situ hybridization was performed
158 according to the kit instructions, and the main steps were: firstly, paraffin sections
159 were routinely dewaxed, then proteinase K was briefly digested for 5 min in a 37°C
160 incubator, closed and denatured, then the probe was diluted and mixed with biotin
161 according to the kit instructions (i.e. Biotin-probe + SA-Cy3), and then added
162 dropwise to the sections for hybridization, and after the hybridization reaction, the
163 sections were washed with washing solution The sections were washed 15 min × 3
164 times after the hybridization reaction, and finally the nuclei were stained with
165 4',6-diamidino-2-phenylindole (DAPI). For co-staining with other proteins, after
166 probe hybridization and before nucleation, the corresponding fluorescently labeled
167 secondary antibody was added, and since the corresponding protein would be reduced
168 after proteinase K digestion, the antibody concentration was increased and incubated
169 for 30 min at 37°C in the incubator, followed by nucleation.

170 **Flow cytometry**

171 The tissue was digested with trypsin into single cells, the medium was
172 neutralized and digested and centrifuged to remove the trypsin, the cells were
173 resuspended with PBS (1×10^6 cells/ml), then fluorophore-labeled flow antibody was
174 added and a blank cell without antibody was set up simultaneously, incubated for 30
175 min at room temperature in closed incubation on ice, and then the cells were sorted on
176 a flow cytometer (BD, BD Aria II).

177 PE patients and control CTB, EVT, HTR-8 cells treated with hypoxia and their
178 controls were loaded into 6-well plates at a density of 1×10^4 cells/ml (three
179 experiments were repeated) and incubated overnight at 37°C at 5% CO₂ as usual. Add
180 5 μl of Annexin V (BD, Shanghai) and incubate for 15 min at room temperature,
181 protected from light. Add PI (BD, Shanghai), take a slide to form a small chamber,
182 take the above stained cell suspension from each centrifuge tube and add it to the
183 small chamber, cover the slide and observe the apoptosis by flow cytometry.

184 **Protein mass spectrometry analysis**

185 The proteins were removed from PE patients after immunoprecipitation from
186 -80 °C and lysed by ultrasound. Protein concentration was determined using BCA kit
187 (Beyotime, Shanghai, China). Equal amounts of each sample protein were taken for
188 enzymatic digestion, and the volume was adjusted to the same level with the lysis
189 solution, then DL-Dithiothreitol (DTT, Sigma-Aldrich, Germany) was added to a final
190 concentration of 5 mM, and reduced at 56 °C for 30 min. Tetraethylammonium
191 bromide (TEAB, Sigma-Aldrich, Germany) was added to dilute the urea to a

192 concentration below 2 M. Trypsin was added at a ratio of 1:50 (protease:protein, m/m)
193 and digested overnight. The peptides were solubilized with liquid chromatography
194 mobile phase A and separated using an EASY-nLC 1200 UHP system. Mobile phase
195 A was an aqueous solution containing 0.1% formic acid and 2% acetonitrile; mobile
196 phase B was an aqueous solution containing 0.1% formic acid and 90% acetonitrile.
197 The liquid phase gradient settings were: 0-62 min, 4%-23% B; 62-82 min, 23%-35%
198 B; 82-86 min, 35%-80% B; 86-90 min, 80% B, and the flow rate was maintained at
199 500 nL/min. The peptides were separated by the UHPLC system and then injected
200 into the NSI ion source for ionization and then into the Q Exactive™ HF-X mass
201 spectrometer for analysis. HF-X mass spectrometry was used for analysis. The ion
202 source voltage was set at 2.1 kV and the peptide parent ions and their secondary
203 fragments were detected and analyzed using a high-resolution Orbitrap. The primary
204 mass spectrometry scan range was set to 400 - 1500 m/z, and the scan resolution was
205 set to 120,000; the secondary scan resolution was set to 15,000. The secondary mass
206 spectrometry was performed. In order to improve the effective utilization of the mass
207 spectrum, the automatic gain control (AGC) was set to 5E4, the signal threshold was
208 set to 2.5E5 ions/s, the maximum injection time was set to 40 ms, and the dynamic
209 exclusion time of the tandem mass spectrometry scan was set to 30 s seconds to avoid
210 repeated scanning of the parent ions.

211 **Cell clustering and differentially expressed genes (DEGs)**

212 The Seurat package (31) was used for cell clustering of scRNA-seq data and to
213 visualize clusters using the UMAP package (32). To define clusters, clusters
214 characterized by similar marker genes were combined into one cell type, and
215 subsequently marker genes for known cell types were used to define the partitioned
216 cell clusters. In addition, the DEGs in each cell type of control donor and PE patient
217 placental tissue were identified by the "FindAllMarkers" function of the Seurat
218 package. Differences associated with adjusted P values, adjusted $P < 0.05$, were
219 considered significant.

220 **Gene Regulatory Network (GRN)**

221 The Single Cell Regulatory Network Inference and Clustering (SCENIC)
222 algorithm has been developed to evaluate regulatory network analysis associated with
223 transcription factors (TFs) and to discover regulators (i.e., TFs and their target genes)
224 in individual cells. To reconstruct gene regulatory networks from scRNAseq data in
225 control donors and PE patients, we performed SCENIC analysis, which uses
226 co-expression modules between TFs and candidate target genes, as well as a database
227 of DNA binding patterns of TFs to infer important gene regulation of transcription
228 factors (33, 34). Regulon modules based on regulon crosstalk (correlation between
229 regulons and regulators) were determined by the connection specificity index (CSI),
230 which ranks the importance of regulons and mitigates the effect of non-specific
231 interactions, and visualized based on the R package ComplexHeatmap (35).

232 **Pseudo-Time Analysis**

233 In this study, single-cell trajectory analysis of cell subtypes was performed as
234 needed. The R package Monocle 3 was applied to sort cells along the trajectory in
235 pseudo-time (<https://cole-trapnell-lab.github.io/monocle3>) (36). After clustering the
236 cells using the above method, the dimensionality was reduced and the results were
237 visualized using the UMAP method. Subsequently, cells were sorted according to
238 their progression through the developmental program. Monocle measured this
239 progression in pseudo-time.

240 **Functional enrichment analysis**

241 Gene ontology (GO) enrichment of cell clusters and Kyoto Encyclopedia of
242 Genes and Genomes (KEGG) pathway analysis were used to determine the biological
243 significance of each cell type. GO and KEGG pathway analysis was performed using
244 the clusterProfiler package for marker genes for each cell subpopulation (37). In
245 addition, Gene Set Enrichment Analysis (GSEA) was performed on DEGs (38) using
246 `c2.cp.kegg.v7.0.symbols.gmt` from the MsigDB database (39) as a background set.
247 GSEA was performed using the clusterProfiler package to perform and $P < 0.05$ was
248 considered significant.

249 **Analysis of intercellular communication**

250 To further explore the interactions between different cell subpopulations, cellular
251 communication analysis was performed using the R language iTALK package.
252 iTALK identifies genes that are highly or differentially expressed in cell clusters and
253 matches and pairs these genes through a receptor-ligand database to find important
254 cellular intercellular communication events. Receptor-ligand interactions were
255 determined using the STRING database of protein-protein interactions (40).

256 **Molecular docking**

257 The three-dimensional structural (41) of the lactate molecule was downloaded
258 from PubChem (<https://pubchem.ncbi.nlm.nih.gov/>), a public repository for biological
259 activity data of small molecules and RNAi reagents. And the three-dimensional
260 structure of PTBP1 protein was downloaded from the Protein Data Bank
261 (<https://www.rcsb.org>) (42), and the binding sites and energy predictions of the lactate
262 molecule and PTBP1 protein were evaluated by Autodock (43). In addition, Hex 8.0.0
263 (44) was used to predict the binding sites and binding potential of PTBP1 protein to
264 IGF2BP2 RNA molecules before and after lactylation. Pymol (45) was applied to
265 visualize the docking model. Docking energy less than 0 indicates that the two have
266 binding potential, and the lower the energy the higher the binding potential.

267 **Data Analysis and Statistics**

268 In this study, all analyses were performed based on the Bioinformcloud platform
269 (<http://www.bioinformcloud.org.cn>).

270 **Results**

271 **Global single-cell landscape of the PE patients placenta**

272 The analytical flow of this study is shown in **Figure 1A**. Based on single-cell
273 sequencing, we constructed a global single-cell landscape of PE patients placenta
274 involving 46 cell clusters of 26,416 cells. These cell clusters were identified into 12
275 cell types based on known markers, including Hofbauer, cytotrophoblasts (CTB),
276 neutrophils, extravillous trophoblasts (EVT), blood cells (BC), maternal uterine
277 dendritic cells (DC), syncytiotrophoblasts (STB), eosinophils, B cells, T cells,
278 placental endothelial cells (En), and ecdysteroid cells (Dec) (**Figure 1B**). Each cell
279 type showed specific expression of cell type markers (**Figure 1C**). Specifically,
280 multiplex immunofluorescence experiments revealed that EVTs from PE patients
281 placenta had less vascular endothelial growth factor receptor 1 (FLT1) relative to
282 controls placenta (**Figure 1D**), whereas EVTs from the PE group had higher levels of
283 lactic acidification modifications (**Figure 1E**). Overall, we constructed a global
284 single-cell atlas of PE and control placenta with precise cell type annotation, depicted
285 cellular ecological differences between PEs and controls placenta, and experimentally
286 validated the levels of abnormal angiogenesis and lactic acidification modifications in
287 EVTs.

288 **CTB cells in PE patients significantly inhibit cell cycle activation of apoptotic** 289 **signaling**

290 During human pregnancy, placenta-derived CTB can differentiate into EVT
291 subpopulations involved in placental angiogenesis, which in turn play a key role in
292 normal fetal growth and development. Therefore, dysfunction of these subpopulations
293 may be an initiating risk factor mediating the development of PE. To this end, CTB
294 cells were extracted for subpopulation identification to explore the possible
295 mechanisms involved in these subpopulations in PE. A total of 14 subpopulations
296 were obtained through the identification of CTB subpopulations (**Figure 2A**). Further
297 comparison of cell abundance revealed that the proportion of cellular CTB_CA8
298 subpopulation was significantly increased and the proportion of CTB_SGMS2
299 subpopulation was significantly decreased in PE, and these two subpopulations were
300 identified as specific CTB subpopulations (**Figure 2B**), and the expression of CA8
301 and SGMS2 was subsequently mapped in the single cell profiles of CTB
302 subpopulations (**Figure 2C**). To further explore the mechanism of CTB subpopulation
303 involvement in PE, we extracted marker genes of CTB_CA8 subpopulation and
304 CTB_SGMS2 subpopulation for enrichment analysis. The results showed that the
305 HIF-1 signaling pathway, apoptosis and TNF signaling pathway were significantly
306 enriched in the CTB_CA8 subpopulation, while the cell cycle was significantly
307 enriched in the CTB_SGMS2 subpopulation (**Figure 2D**). The KEGG pathway map
308 further revealed that the cell cycle activity of CTB_CA8 cell subpopulation was
309 reduced, while HIF-1 signaling pathway, apoptosis and necroptosis pathway were
310 significantly activated (**Figure 2E**). Apoptosis and necroptosis were found to be more
311 pronounced in PE by flow cytometry experiments (**Figure 2F**). Subsequent proposed
312 chronological analysis revealed the developmental trajectory of CTB subpopulations,

313 and both specific CTB subpopulations were in an early developmental position
314 (**Figure 2G**). GRN revealed that CTB subpopulation marker genes were divided into
315 4 modules (**Figure 2H**), which were mainly regulated by TFs such as HEY2, HOXB6
316 and ELF4 (**Figure 2I**). In conclusion, we identified significant cell cycle suppression
317 and activation of apoptotic signaling by CTB cells in PE, and inferred the origin and
318 trajectory of CTB cell pathogenesis and evolution, and constructed a GRN of CTB
319 cells in the development and progression of PE.

320 **PE patients-specific EVT_CSNK2B cell subpopulation and control** 321 **EVT_FUCA1_FLNB cell subpopulation**

322 Pregnancy is a complex and delicate process, and after blastocyst implantation in
323 early gestation, placental EVT cells further invade, migrate and differentiate towards
324 the metaplastic and myometrial vasculature of the uterus, initiating and completing
325 vascular remodeling, which is a critical part of establishing maternal-fetal circulation.
326 Therefore, we also extracted EVT cells for subpopulation identification and captured
327 a total of 6 EVT subpopulations (**Figure 3A**). By comparing the cell abundance, it
328 was found that the proportion of EVT_CSNK2B subpopulation was significantly
329 increased in PE compared with the control, while the proportion of
330 EVT_FUCA1_FLNB subpopulation was significantly decreased (**Figure 3B**).
331 Enrichment analysis revealed that markers of EVT_CSNK2B subpopulation were
332 significantly involved in pathways such as necroptosis, iron death, and HIF-1
333 signaling pathway, while markers of EVT_FUCA1_FLNB subpopulation were
334 significantly involved in pathways such as adhesive junctions, adherent spots, and
335 tight junctions (**Figure 3C**). Subsequently, the expression of CSNK2B and FUCA1
336 was mapped in the single-cell profiles of EVT subpopulations, while
337 immunofluorescence showed low FLNB expression and high CSNK2B expression in
338 EVT cells with PE (**Figure 3D**), which was consistent with the results of the raw
339 signal analysis (**Figure 3B**). The GRN of EVT cell subpopulations suggested that the
340 markers of EVT cells were divided into 5 modules in total (**Figure 3F**) and regulated
341 by MAFG, SRF, KLF7, and ETV4 TFs (**Figure 3G**). In conclusion, we identified
342 subpopulations of EVT cells in PE and the pathways they participate in, inferred the
343 origin and trajectory of the evolution of EVT cell pathology, and constructed a GRN
344 of EVT cells in the development and progression of PE.

345 **Inhibition of IGF2BP2 expression causes defective mitochondrial autophagy and** 346 **adherent patch signaling in EVT of PE patients**

347 As a specific subpopulation of EVT, the EVT_CSNK2B subpopulation may play
348 an important role in the development of PE. Therefore, to further explore the potential
349 mechanisms involved in the development of PE, we performed GSEA on the
350 EVT_CSNK2B subpopulation. The results showed that mitochondrial autophagy,
351 adherent spots and associated metabolic signals were inhibited in the EVT_CSNK2B
352 subpopulation (**Figure 4A**). We then constructed a comprehensive regulatory network
353 of upstream regulators (IGF2BP2, PLXNB2, TCF7L2, MBNL2, MYC, RBFOX2,

354 MLLT1, NEAT1) on mitochondrial autophagy, adherent spots and associated
355 metabolic signaling in the EVT_CSNK2B cell subpopulation (**Figure 4B**).
356 Intriguingly, IGF2BP2 is an N6-methyladenosine (m⁶A)-associated gene that
357 enhances mRNA stability and promotes translation as an m⁶A reader protein.
358 Therefore, we mapped its expression in single-cell profiles of EVT subpopulations
359 and found that IGF2BP2 was widely expressed in the dominant subpopulation of
360 control pregnant women, EVT_FUCA1_FLNB, yet significantly reduced in the
361 PE-specific EVT_CSNK2B cell subpopulation (**Figure 4C**). Furthermore, multiplex
362 immunofluorescence experiments confirmed that IGF2BP2 was lowly expressed in
363 EVT cells from placenta in the PE patients compared to controls (**Figure 4D, E**).
364 Briefly, inhibition of IGF2BP2 expression in PE causes defective mitochondrial
365 autophagy and adherent spot signaling in EVT.

366 **Hypoxia promotes PTBP1 lactonization leading to PTBP1 inactivation inhibiting** 367 **RNA processing and synthesis of IGF2BP2 mediating the disease process of PE**

368 However, it is puzzling what causes the suppression of RNA expression of
369 IGF2BP2 in PE. To this end, we identified the core molecule regulating IGF2BP2
370 expression PTBP1. Notably, there was no significant difference in the protein
371 abundance of PTBP1 in EVT cells from PE patients in multiplex immunofluorescence
372 assays (**Figure 5A**), and there was no binding of PTBP1 protein and IGF2BP2 probe
373 in EVT cells from PE patients with hyperlactation, but there was binding in controls,
374 suggesting that PTBP1 protein in placental EVT from PE patients had a weaker
375 ability to bind RNA molecules of IGF2BP2 (**Figure 5B**). Furthermore, the binding
376 potential of PTBP1 and lactic acid small molecules was identified by molecular
377 docking (**Figure 5C**), indicating that PTBP1 protein is capable of lactonization and
378 that the structure of lactonized PTBP1 protein is disrupted. In addition, the
379 post-lactated PTBP1 protein had a much lower RNA binding potential to IGF2BP2
380 (**Figure 5D**).

381 The effect of suppression of RNA expression of IGF2BP2 on PE has not been
382 clarified. Therefore, we explored in depth the mechanisms involved in IGF2BP2
383 inhibition. First, we found that the mitochondrial autophagic pathway in
384 EVT_CSNK2B cell subpopulation was significantly activated (**Figure 5E**). Flow
385 cytometry showed that mitochondrial autophagy was inhibited after placental EVT
386 cells were treated with hypoxia (**Figure 5F**), and not only that, the cells showed early
387 apoptosis and necrotizing apoptosis in EVT cells of PE and hypoxic HTR-8 cell line
388 (**Figure 5G**).

389 Since significant activation of adherent spot signals is a major manifestation of
390 cell migration and invasion, we also explored the activation of invasion-related
391 signals such as adherent spots in EVT subpopulations after IGF2BP2 inhibition. We
392 found that adherent patch signaling was significantly suppressed in the
393 EVT_CSNK2B cell subpopulation (**Figure 5H**), and in addition, multiple
394 immunofluorescence experiments confirmed that the expression of the key molecule

395 of adherent patch signaling (CAPN2) was suppressed in EVT cells from PE patients
396 **(Figure 5I)**.

397 In summary, our results show that lactylation of PTBP1 in EVT cells under
398 hypoxic microenvironment leads to its inactivation, inhibits RNA processing
399 synthesis of IGF2BP2, promotes damage depletion of mitochondria and inhibits
400 mitochondrial autophagy, causing accumulation of damaged mitochondria, inducing
401 apoptosis and necrotic apoptosis of EVT cells while blocking lactate metabolism and
402 intensifying lactate accumulation, forming a feedback It also inhibits the EVT
403 adhesion spot signaling pathway and weakens the invasive ability of EVT, leading to
404 insufficient reconstruction of placental spiral vasodilation and forming a feedback
405 vicious external loop. The continued activation of the malignant internal and external
406 dual circulation system in the hypoxic microenvironment drives the disease process of
407 PE **(Figure 5J)**.

408 **Microenvironmental immune cell ecology of the placenta in PE**

409 During different periods of pregnancy, the immune microenvironment at the
410 maternal-fetal interface exhibits a dynamic balance, which facilitates the
411 establishment and maintenance of pregnancy as well as fetal growth and development.
412 To this end, we extracted immune cells from PE patients placenta for subpopulation
413 identification to explore the microenvironmental immune cell ecology of PE patients
414 placenta. A total of 11 subpopulations were captured by subpopulation identification
415 of the indicated Hofbauer cells **(Figure 6A)**, and the distinctive markers of these
416 subpopulations are shown **(Figure 6C)**. Among them, the Hofbauer_ALPL_NBN
417 subpopulation was significantly reduced in proportion in PE, while the
418 Hofbauer_BTG3 subpopulation was significantly increased **(Figure 6B)**. For
419 Neutrophils, a total of 5 subgroups were captured, of which the Neutrophils_S100A12
420 subgroup had a significantly higher proportion in PE, while the markers of these
421 subgroups are shown **(Figure 6D-F)**. For DCs, a total of 5 subpopulations were
422 captured **(Figure 6G)**, and the proportion of
423 DC_NEU1_IGF1_CBLB_PDE2A_BCL2L1 subpopulation was significantly elevated
424 in PE **(Figure 6H-I)**. For T cells, a total of 7 subpopulations were captured **(Figure**
425 **6J)**, with the proportion of T_CHPT1 subpopulation and T_LRRN3 subpopulation
426 significantly elevated in PE **(Figure 6K-L)**. Overall, by exploring the differences in
427 the composition of these immune cell subpopulations in controls and PE patients
428 placenta, we preliminarily characterized the immune cell ecology of the
429 microenvironment in PE.

430 **Abnormal metabolic signaling of PE patients-specific EVT subpopulations** 431 **interacts with microenvironmental immune cells to activate metabolic** 432 **inflammation**

433 Previous studies have shown that each week of pregnancy involves a plethora of
434 physiological changes and metabolic adaptations, and that even small deviations from
435 normal norms may have adverse consequences at different stages of pregnancy.

436 Therefore, we explored the interaction of abnormal metabolic signaling in EVT
437 subpopulations with microenvironmental immune cells. Based on KEGG pathway
438 maps, we found that the EVT_CSNK2B cell subpopulation significantly promoted
439 glutathione (anti-inflammatory metabolite) metabolism, inhibited sphingolipid
440 (pro-inflammatory metabolite) metabolism, and suppressed the biosynthesis of
441 various glycans (anti-inflammatory metabolites) (**Figure 7A**). The prevalence of
442 interactions between the EVT_CSNK2B subpopulation of PE and immune cell
443 subpopulations was revealed by cell communication analysis (**Figure 7B**), and the
444 genes for these interactions were further demonstrated (**Figure 7C**). GSEA showed
445 that immune cell clusters of PE, including Hofbauer cells, Neutrophils cells, DCs, and
446 T cells, generally significantly activated immune inflammation-related pathways
447 (**Figure 7D-G**). Taken together, these results suggest an interaction between abnormal
448 metabolic signaling of PE patients-specific EVT subpopulations and
449 microenvironmental immune cells, which activates metabolic inflammation.

450 **Discussion**

451 This study provides a comprehensive and in-depth dissection of cellular
452 dynamics in the placenta of PE patients from single-cell sequencing data, thus
453 enabling the elucidation of the abnormal molecular and cytopathological ecology of
454 protein hyperlactation-mediated PE in the hypoxic microenvironment under complex
455 pathological conditions.

456 In the global single-cell ecosystem of PE, we found an increased proportion of
457 carbonic anhydrase 8 (CA8)-positive CTBs (CTB_CA8) in almost all patients,
458 accompanied by reduced cell cycle activity and significant activation of the HIF-1
459 pathway and apoptotic cell death pathways. CTB cells in the placenta of PE patients
460 undergo excessive cell death, including apoptosis, and if left unchecked, these
461 processes lead to apoptosis sweeping throughout the syncytium eventually stimulating
462 extensive death at this fundamental interface of maternal-fetal exchange (46, 47).
463 Thus, maintaining homeostasis of the trophoblastic hypoxic microenvironment is
464 essential to slow or inhibit PE progression. In addition, studies have captured an
465 abnormally increased subpopulation of CSNK2B-positive EVT in the placenta of PE
466 patients. Based on comprehensive regulatory network analysis of this subpopulation,
467 m⁶A reading protein insulin-like growth factor 2 mRNA binding protein 2 (IGF2BP2)
468 was identified as a key regulator involved in mitochondrial autophagy and adherent
469 plaque signaling pathways. IGF2BP2 is one member of the IGF2BP family that has
470 previously been regarded as oncofetal, as its members were originally discovered in
471 developing embryos (48). IGF2BP2 is an important gene associated with type 2
472 diabetes (49). Another IGF2BP family member, IGF2BP3, was found to stimulate
473 trophoblast cell invasion and migration. In addition, in recent studies, IGF2BP2 was
474 confirmed which trophoblast cells invade and migrate. However, no study has yet
475 investigated the invasion and migration of IGF2BP2 at the single cell level in PE (50,
476 51). It is well known that post-transcriptional modifications of messenger RNAs
477 (mRNAs), among which m⁶A is the most abundant internal RNA modification,

478 regulate genes expression by influencing mRNA splicing, stability, translocation and
479 translation (52). Moreover, m⁶A modification exerts its biological functions by
480 “readers”: YTH (YT521-B homology) domain proteins including YTHDC1-2 and the
481 YTH-family proteins YTHDF1–3 as well as insulin-like growth factor 2 mRNA
482 binding proteins IGF2BP1-3 (53). Among these m⁶A readers, IGF2BP2 binds RNA
483 via its six characteristic RNA-binding domains, containing two RNA recognition
484 motifs (RRM1 and RRM2) and four K Homology (KH) domains (KH1-KH4) (54).

485 In addition, we identified a core regulator, polypyrimidine bundle-binding
486 protein 1 (PTBP1), in a study of lactonization in a CSNK2B-positive EVT
487 subpopulation. Previous studies have demonstrated that PTBP1 is a known regulator
488 of post-transcriptional gene expression with representative roles in controlling mRNA
489 splicing, translation, stability and localization, and more strikingly, recent studies
490 have identified its involvement in glycolytic processes. PTBP1 is a key determinant of
491 pyruvate kinase isoform 2 in PKM embryos and is used to promote aerobic glycolysis
492 (55-58). PTBP1 is closely related to the initial formation of the embryo, and PTBP1
493 serves as a factor essential for early embryonic development, especially because it is
494 necessary for rapid cell division and is essential for embryonic stem cell proliferation
495 (59). However, its potential role and specific molecular mechanisms have not been
496 reported in PE. Our study concluded that the mechanism of IGF2BP2 low expression
497 contributes to the poor internal and external circulation of PE. First, PTBP1
498 lactonization mediates its inactivation and drives IGF2BP2 low expression, which in
499 turn inhibits mitochondrial autophagy and leads to the continuous accumulation of
500 damaged mitochondria, blocking cellular lactate metabolism for energy while
501 promoting EVT apoptosis and further accumulation of lactate, resulting in a feedback
502 poor internal circulation. Second, PTBP1 lactation-mediated IGF2BP2 low expression
503 also significantly inhibits the adherent plaque signaling pathway, which significantly
504 reduces the invasive capacity of EVT and becomes a persistent obstacle to spiral
505 artery reconstruction, further exacerbating the placental ischemic and hypoxic
506 microenvironment and creating a feedback adverse external circulation. A recent
507 study by Vangrieken P found signs of increased oxidative stress and mitochondrial
508 dysfunction in the placenta of PE, suggesting that mitochondria could be a potential
509 novel therapeutic target in PE (60). In previous studies, mitochondrial autophagy was
510 considered as a cellular defense that removes excess mitochondrial fragments in PE
511 (61). However, in the present study, mitochondrial autophagy was found to be
512 inhibited in EVT cells of PE patients. The HIF-1 signaling pathway was significantly
513 activated, suggesting that hypoxia induces oxidative stress in PE. Furthermore,
514 migration/invasion of EVT cells is tightly regulated by some adhesion molecules,
515 mainly in an autocrine or paracrine manner at the fetal-maternal interface in human
516 pregnancy (62). In the present study, the expression of genes related to adhesive patch
517 signaling was found to be significantly downregulated in PE, suggesting that m⁶A
518 methylated IGF2BP2 reading defects inhibit adhesive patch signaling and reduce the
519 invasive capacity of EVT cells.

520 Analysis of PE patients placental microenvironmental immune cells in
521 combination with EVT showed that the microenvironmental immune cell function in
522 PE is mainly focused on immune response, suggesting that placental immune function
523 is altered in PE patients. On the one hand, EVT requires remodeling of the uterine
524 spiral arteries, as well as invasion of the metaplastic tissue of the uterus and anchoring
525 of the placenta to the uterine wall. During these processes, different types of
526 microenvironmental immune cells are encountered (63). In order to adapt to each
527 other, a rational immune regulation is necessary.

528 In summary, our study establishes a large-scale single-cell transcriptome
529 ecological landscape of normal and PE patients placenta and demonstrates changes in
530 cellular dynamics in PE patients placenta, elucidating the abnormal ecological balance
531 of molecular and cellular physiopathology mediated by protein hyperlactation in PE
532 in the hypoxic microenvironment. This opens an avenue to resolve cellular dynamics
533 and aberrations in the complex biological system of PE and to establish a molecular
534 diagnosis of PE. However, the current study still has some limitations. Firstly, our
535 results should be validated in a large-scale study due to the insufficient sample size.
536 Second, the interactions between these abnormal cells in PE deserve further
537 investigation.

538 **Data Availability Statement**

539 The datasets analyzed during the current study are available in the GEO database
540 (<https://www.ncbi.nlm.nih.gov/geo/>).

541 **Conflict of interests**

542 The authors report no conflicts of interest related to this work.

543 **Funding**

544 This research was supported by the Natural Science Foundation of Shandong
545 Province (ZR2021MH223).

546 **Acknowledgments**

733 **Figure legend**

734 **Figure 1. Global single-cell landscape of PE patients placenta.** A. Study flow of
 735 this work. A global single-cell landscape of PE patients placenta was constructed
 736 based on single-cell technology, capturing a total of 26,416 cells from 46 cell clusters.
 737 B. Single-cell atlas mapping cell types, including fetal macrophages (Hofbauer),
 738 cytotrophoblasts (CTB), Neutrophils, extravillous trophoblasts (EVT), blood cells
 739 (BC), maternal uterine dendritic cells (DC), syncytiotrophoblasts (STB), Eosinophils,
 740 B cells, T cells, placental endothelial cells (En), and ecdysteroid cells (Dec). C.
 741 Bubble plots showing cellular markers guiding cell annotation. D. Multiplex
 742 immunofluorescence plots showing PEs and controls extravillous trophoblast (EVT)
 743 and endothelial landscapes. Highlights are erythrocytes, compared to more
 744 vascular/hematocrit in the controls and less in the PEs. E. Multiplex
 745 immunofluorescence map demonstrating the level of lactonization modification of
 746 EVT in the PEs and controls.

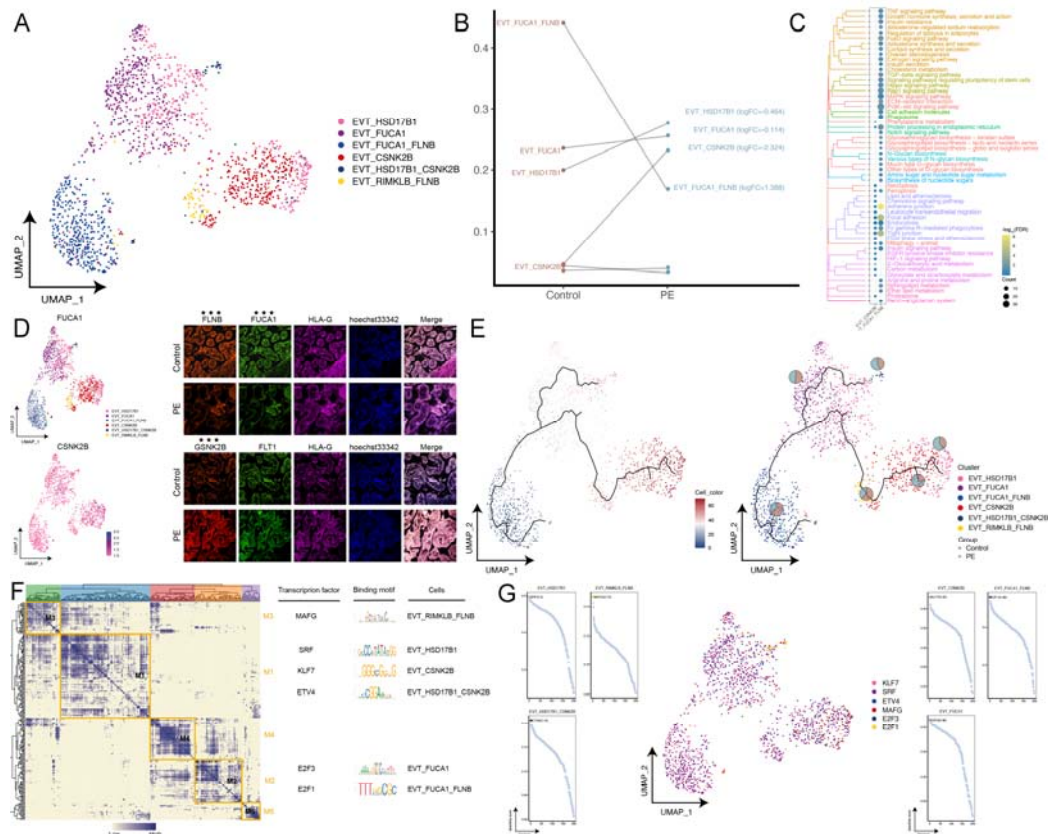

748 **Figure 2. Identification of CTB subpopulations in PE patients and exploration of**
 749 **the mechanisms involved.** A. Single-cell atlas demonstrating CTB subpopulations. B.
 750 Changes in the ecological composition of CTB in Controls-PEs. C. Markers of PE
 751 patients-specific CTB. D. Biological pathways significantly involved in CTB_CA8
 752 and CTB_SGMS2 cell subpopulations. E. Activation or inhibition of cell cycle, HIF-1
 753 signaling pathway, apoptosis and necroptosis pathways in CTB_CA8 cell
 754 subpopulations. F. Flow cytometry experiments to verify apoptosis and necroptosis in
 755 CTB from PE patients and controls. G. Pseudotime analysis of CTB subpopulations in
 756 PE patients. H. GRN of CTB cell subpopulations in PE patients. I. CTB
 757 subpopulation-specific transcription factors in PE patients.

770

771 **Figure 4. Inhibition of IGF2BP2 expression causes defective mitochondrial**
 772 **autophagy and adherent patch signaling in EVT of PE patients.** A.
 773 EVT_CSNK2B cell subpopulation significantly inhibits mitochondrial autophagy,
 774 adherent spots and associated metabolic signaling. B. Network diagram demonstrating
 775 the regulation of mitochondrial autophagy, adherent spots and related metabolic
 776 signaling by upstream regulators in EVT_CSNK2B cell subpopulation. C. Single cell
 777 profiles demonstrating the expression of IGF2BP2. D-E. Multiplex
 778 immunofluorescence assays to verify the RNA and protein abundance of IGF2BP2 in
 779 EVT cells from PE patients and controls.

780

781

782 **Figure 5. Hypoxia promotes PTBP1 lactylation leading to PTBP1 inactivation**
783 **inhibiting the processing of RNA synthesis of IGF2BP2 mediating the disease**
784 **process of PE patients.** A. Multiplex immunofluorescence assay to verify the protein
785 abundance of PTBP1 in EVT from PE patients and controls. B. Multiplex
786 immunofluorescence assay to verify the ability of PTBP1 protein to bind RNA
787 molecules of IGF2BP2 in PE patients (hyperlactylated) and control (hypolactylated)
788 EVT. C. Molecular docking predicts the binding site and potential of PTBP1
789 lactylation modification. D. Molecular docking predicts the binding sites and potential
790 of PTBP1 protein to IGF2BP2 RNA molecules before and after lactylation. E.
791 Activation or inhibition of mitochondrial autophagy in EVT_CSNK2B and
792 EVT_FUCA1_FLNB cell subpopulations. F. Flow cytometry validation of
793 mitochondrial autophagy in EVT from PE patients and controls. G. Flow cytometry
794 validation of apoptosis and necrotizing apoptosis in PE patients, control EVT and
795 HTR-8 cell lines before and after hypoxia treatment. H. Activation or inhibition of
796 adherent spot signaling in EVT_CSNK2B and EVT_FUCA1_FLNB cell
797 subpopulations. I. Multiplex immunofluorescence assay to verify the activation or
798 inhibition of adherent spot signaling in EVT from PE patients and controls. J. Under
799 normal conditions, PTBP1 protein promotes the processing and synthesis of IGF2BP2,
800 which in turn promotes the mitochondrial autophagy and adherent patch pathway and
801 inhibits the apoptotic and necroptotic pathways in EVT. However, lactylation of
802 PTBP1 protein in EVT under hypoxic microenvironment leads to its inactivation,
803 which in turn blocks the processing and synthesis of IGF2BP2 RNA, and the
804 suppressed expression of IGF2BP2 drives the disease process of PE through two
805 pathways. Pathway 1: Promotes damage depletion of mitochondria and inhibits
806 mitochondrial autophagy, causing accumulation of damaged mitochondria, inducing
807 apoptosis and necroptosis of EVT while blocking lactate metabolism and exacerbating
808 lactate accumulation, forming a feedback vicious inner circle; Pathway 2: Inhibits the
809 adhesive patch signaling pathway of EVT, weakening the invasive ability of EVT and
810 leading to insufficient reconstruction of placental spiral vasodilation, forming a
811 feedback vicious external circulation.

812

813

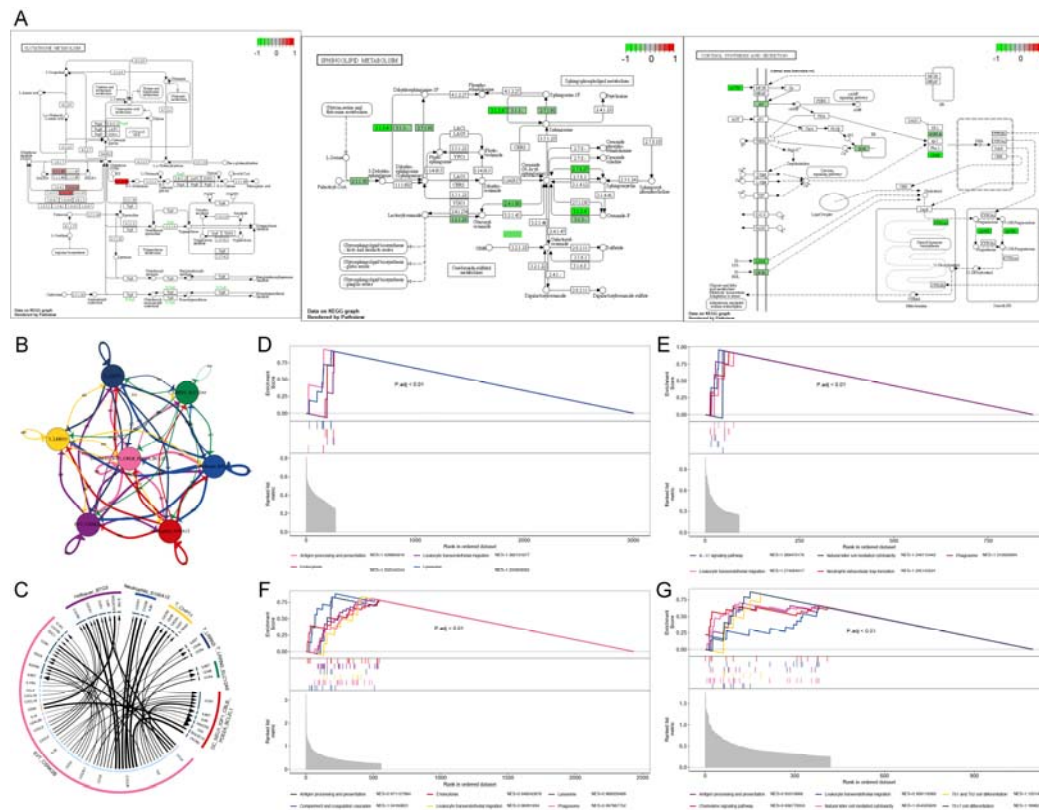

814 **Figure 6. Exploration of the microenvironmental immune cell ecology of the**
 815 **placenta of PE patients.** A. Single-cell atlas demonstrating Hofbauer cell
 816 subpopulations. B. Variation in the ecological composition of Hofbauer cells in
 817 PEs-Controls. C. Violin diagram demonstrating markers of PE-specific Hofbauer cell
 818 subpopulations. D. Single-cell plots demonstrating Neutrophils cell subpopulations. E.
 819 Changes in the ecological composition of Neutrophils cells in PEs-Controls. F. Violin
 820 diagram showing markers of PE-specific Neutrophils cell subpopulations. G.
 821 Single-cell plots demonstrating DC cell subpopulations. H. Dotted line diagram
 822 demonstrating changes in the ecological composition of DC cells in PEs-Controls. I.
 823 Violin diagram showing markers of PE-specific DC cell subpopulations. J. Single-cell
 824 mapping demonstrating T cell subpopulations. K. Variation in the ecological
 825 composition of T cells in PEs-Controls. L. Violin diagram demonstrating markers of
 826 PE-specific T cell subpopulations.

827

828

829 **Figure 7. Interaction of abnormal metabolic signaling of PE patients-specific**
 830 **EVT subpopulations with microenvironmental immune cells is explored. A.**
 831 **EVT_CSNK2B cell subpopulation significantly promotes glutathione**
 832 **(anti-inflammatory metabolite) metabolism, inhibits sphingolipid (pro-inflammatory**
 833 **metabolite) metabolism, and suppresses biosynthesis of various glycans**
 834 **(anti-inflammatory metabolites). B and C. Overview of communication events**
 835 **between PE patients-specific EVT_CSNK2B subpopulations and immune cell**
 836 **subpopulations. D. Immunoinflammatory pathways significantly activated by PE**
 837 **patient-specific Hofbauer cells. E. Immunoinflammatory pathways significantly**
 838 **activated by PE patients-specific Neutrophils cells. F. Immunoinflammatory pathway**
 839 **significantly activated by PE patients-specific DC cells. G. Immunoinflammatory**
 840 **pathways significantly activated by PE patients-specific T cells.**
