## Materials and Methods

#### Participants

The Public Health Impact of Metal Exposure (PHIME) study is a longitudinal cohort study of adolescents and young adults living in northern Italy. Details of the study have been described elsewhere<sup>19,20</sup>. Inclusion criteri young adults living in northern Italy. Details of the study have been described elsewhere<sup>49,20</sup>. Inclusion criteria<br>were: birth in the areas of interest; family residence in Brescia for at least two generations; residence were interest; family residence in the areas of interest; family and the patic, metabolic, endocrine or psychiatric disorder; having clinically diagnosed motor deficits or cognitive impairment and having visual deficits th statute disorder; having clinically diagnosed motor deficits or cognitive impairment and having visual<br>deficits that are not adequately corrected. Detailed description of this recruitment process and study design<br>can be fo deficits that are not adequately corrected. Detailed description of this recruitment process and study des<br>can be found in previous publications<sup>20,21</sup>. Between 2016-2021, a convenience-based sample of 207 PHIN<br>participan can be found in previous publications<sup>20,21</sup>. Between 2016-2021, a convenience-based sample of 207 PHIME<br>participants (53% female, ages 13-25 years) participated in a sub-study including multi-modal MRI scans and<br>measures participants (53% female, ages 13-25 years) participated in a sub-study including multi-modal MRI scans and<br>measures of memory and motor functions (Cambridge Neuropsychological Test Automated Battery<br>(CANTAB))<sup>22</sup>. All pa participants (53% female) and motor functions (Cambridge Neuropsychological Test Automated Battery (CANTAB)<sup>22</sup>. All participants satisfied the eligibility criteria for MRI scanning (i.e., no metal implants or shrapnel, cl (CANTAB))<sup>22</sup>. All participants satisfied the eligibility criteria for MRI scanning (i.e., no metal implants or shrapnel, claustrophobia, prior history of traumatic brain injury, and body mass index (BMI)  $\leq$  40). 202 p shrappel, participants completed the MRI and CANTAB tests. These data serve as the baseline in our study.<br>PHIME COVID-19 substudy<br>

#### PHIME COVID-19 substudy

Beginning in March 2021, we invited all 207 participants to an in-person follow-up study (PHIME COVID-19) involving repeated identical MRI protocol and cognitive assessment as administered at baseline (PHIME stu<br>40 (19%) agreed to participate. Of these 40 participants, 16 reported having been infected with SARS-CoV-2<br>(COVID + 40 (19%) agreed to participate. Of these 40 participants, 16 reported having been infected with SARS-CoV-2 (COVID +) based on positive real-time reverse transcription polymerase chain reaction (RT-PCR) for SARS-CoV-2 RNA (COVID +) based on positive real-time reverse transcription polymerase chain reaction (RT-PCR) for SARS-CoV<br>RNA detection that was performed on a nasopharyngeal swab sample at the time of diagnosis. Based on<br>literature su (COVID + in the set of diagnosis. Based on literature suggesting SARS-CoV-2 antibodies titers decrease after 12 months<sup>23,24</sup>, only participants with a positive RT-PCR test within 12 months of follow-up data acquisition we Iterature suggesting SARS-CoV-2 antibodies titers decrease after 12 months<sup>23,24</sup>, only participants with a positive RT-PCR test within 12 months of follow-up data acquisition were considered COVID + (Figure 1).<br>these cri positive RT-PCR test within 12 months of follow-up data acquisition were considered COVID + (Figure 1). Using<br>these criteria, we identified 13 COVID+ and 27 COVID- subjects. Notably, four participants (1 COVID- and 3<br>COVID was performed only on COVID+ participants (available on 13 participants over 16 infected with SARS-CoV-2; COVID+ subjects that were positive but outside the 12 months threshold used to define COVID-19 status)<br>reported mild COVID-19 symptoms and were treated as COVID- (see Table 1). Additional serological screen<br>was performed The multiplet of the 12 subjects that were treated as COVID- (see Table 1). Additional serological scree<br>was performed only on COVID+ participants (available on 13 participants over 16 infected with SARS-COV-<br>Figure 1), re was performed only on COVID+ participants (available on 13 participants over 16 infected with SARS-CoV-2;<br>Figure 1), retrospectively. Serum samples were tested using Euroimmun (Anti-SARS-CoV-2-NCP ELISA (IgG),<br>Order No. E Figure 1), retrospectively. Serum samples were tested using Euroimmun (Anti-SARS-CoV-2-NCP ELISA (IgG), Order No. El 2606-9601-2 G) assay with 80% sensitivity and 99.8%<sup>25</sup>. Results reported in Figure 1 are based or<br>atio o Order No. El 2606-9601-2 G) assay with 80% sensitivity and 99.8%<sup>25</sup>. Results reported in Figure 1 are based or<br>atio of specimen absorbance reported to the cut-off value defined by the manufacturer. None of the COVII<br>posi ratio of specimen absorbance reported to the cut-off value defined by the manufacturer. ratio of permitted to specialized or suffered from pneumonia.<br>The manufacturer positive participants were hospitalized or suffered from pneumonia.<br>Written informed consent was obtained from parents and young adults, partic positive participants were hospitalized or suffered from particle informed and<br>Written informed consent was obtained from parents and young adu<br>written assent. Study procedures were approved by the Institutional<br>California written assent. Study procedures were approved by the Institutional Review Board of the University of<br>California, Santa Cruz and the ethical committees of the University of Brescia, and the Icahn School of Me<br>at Mount Sina California, Santa Cruz and the ethical committees of the University of Brescia, and the Icahn School of N<br>at Mount Sinai.<br>The University of Brescia, and the Icahn School of N California, Santa Cruz and the ethical committees of the University of Bresch, and the Icahn Distribution of Medicine<br>at Mount Sinai.

Figure 1 - COVID+ group definition. PHIME COVID-19 participants were included in the COVID+ group based on: 1) a positive RT-PCR for SARS-CoV-2 RNA detection and, 2) time of diagnosis within 12 months of data acquisition. The relation between the ratio of anti-SARS-CoV-2-NCP (IgG) detected using an ELISA assay and the time between a positive RT-PCR and data acquisition is reported in the figure for each single positive PHIME COVID-19 participant (blue dot). Three COVID+ participants are not included in the figure since the ELISA test is not available. Black dotted line represents the 12 month cut-off used as threshold for participant inclusion in the COVID+ group.

#### Neuropsychological assessment

Trained neuropsychologists administered the standard Cambridge Neuropsychological Test Automated Battery (CANTAB)<sup>22</sup> to assess domains of cognitive, memory and motor functioning. To test our hypothesis on the<br>. impact of COVID-19 on the brain and working memory functions, we used the CANTAB Spatial Working Memory (SWM) test. This test provides a comprehensive evaluation of an individual's ability to retain and manipulate spatial information in working memory. The SWM task detects frontal lobe activity and executive dysfunctions. The participants are shown different colored squares (boxes) on a screen and asked to identify yellow tokens within a box. Participants are instructed to search for tokens by opening boxes (touching each box on the screen) and advised to not return to the same box that already contained a token. These tokens are then used to automatically fill an empty column located on the right side of the screen. The complexity of the<br>task gradually increases as the number of boxes to be searched reaches a maximum of twelve. To discourage task gradually increases as the number of boxes to be searched reaches a maximum of twelve. To discourage the use of stereotypical search strategies, the color and position of the boxes are changed between trials. Several outcome measures are provided by SWM test, including error rates, instances of selecting empty boxes, revisiting boxes that already contain a token, as well as measures of strategy implementation and latency. Here, we focused on the "between error", number of times that a participant selected a box that already contained a token, and "strategy", number of times that a participant selected a new and different box looking for a new token. Both variables are available for 39 participants who completed the CANTAB.

#### MRI and fMRI data acquisition

Magnetic resonance imaging (MRI) and functional MRI (fMRI) data acquisition was performed on a high-Neuroimaging Division of ASST Spedali Civili Hospital of Brescia. For each participant, a high-resolution<br>weighted structural scan was acquired using a MPRAGE sequence (TR =2400 ms, TE= 2.06 ms, TI=230<br>acquisition matrix= weighted structural scan was acquired using a MPRAGE sequence (TR =2400 ms, TE= 2.06 ms, TI=230 ms, acquisition matrix=256x256 and 224 sagittal slices with final voxel size=0.9 mm<sup>3</sup>). Fifty contiguous oblique-axi section acquisition matrix=256x256 and 224 sagittal slices with final voxel size=0.9 mm<sup>3</sup>). Fifty contiguous oblique sections were used to cover the whole brain where the first four images were discarded to allow the magnetizatio acquisition matrix=256x256 and 224 sagittal slices with final voxel size=0.9 mm<sup>3</sup>). Fifty contiguous oblique-axial<br>sections were used to cover the whole brain where the first four images were discarded to allow the<br>magnet Sections were used to cover the whole brain where the mst four images were ulstanded to allow the magnetization to reach equilibrium. For each subject, a single 10-minute continuous functional seque<br>a T2\*weighted echo-planar imaging (EPI) sequence (TR=1000 ms, TE=27 ms, 70 axial slices, 2.1 mm th<br>matrix size 108x108, c magnetization to reach equinous and T2\*weighted echo-planar imaging (EPI) sequence (TR=1000 ms, TE=27 ms, 70 axial slices, 2.1 mm thickness, matrix size 108x108, covering the brain from vertex to cerebellum) was acquired. a T2\* Weighted echo-planar imaging (EPI) sequence (TREF100) was acquired. During resting-state scans, lights of the MRI room were off and participants were instructed to stay awake, relax and daydream (not think<br>about anyt matrix size 108x108, covering the brain from vertex to cover instructed to stay awake, relax and daydream (not thin<br>about anything) with their eyes open. They were presented with an image of a night skyline figure projecte about anything) with their eyes open. MRI and fMRI data analyses

#### MRI and fMRI data analyses

Image pre-processing, eigenvector calculations, and statistical analyses were performed using FreeSurfer Image pre-pre-processing, eigenvector calculations, and the processing of the performance of limaging<br>Individuals (V7.1.1; https://surfer.nmr.mgh.harvard.edu/), SPM12 (Wellcome Department of limaging<br>Neuroscience, London, Neuroscience, London, UK), Brain Connectivity toolbox <sup>26,27</sup> and customized scripts, implemented in<br>2016b (The Mathworks Inc., Natick, Massachusetts) and R (v3.4).<br>MRI processing and analysis Neuroscience, London, UK), Brain Connectivity toolbox <sup>20,27</sup> and customized scripts, implemented in MatLab<br>2016b (The Mathworks Inc., Natick, Massachusetts) and R (v3.4).<br>*MRI processing and analysis* 2016b (The Mathworks Inc., Natick, Massachusetts) and R (v3.4).<br>MRI processing and analysis<br>T1-weighted scans were preprocessed using FreeSurfer to perform cortical and subcortical reconstruction and

#### MRI processing and analysis

segmentation<sup>28-31</sup>. The standard cross-sectional pipeline available in Freesurfer v. 7.1.1 including intensity normalization, automated topology corrections, and automatic segmentation of cortical and subcortical brain areas was applied to each subject. Total intracranial volume (TIV) was also extracted  $31$ .

#### fMRI Image preprocessing

For each subject, the structural MRI was co-registered and normalized against the Montreal Neurological Institute (MNI) template and segmented to obtain white matter (WM), gray matter (GM) and cerebrospinal<br>fluid (CSF) probability maps in the MNI space. FMRI data were spatially realigned, co-registered to the MNI-152<br>EPI te Institute (CSF) probability maps in the MNI space. FMRI data were spatially realigned, co-registered to the MNI-1<br>EPI template and subsequently normalized utilizing the segmentation option for EPI images in SPM12. All<br>norm EPI template and subsequently normalized utilizing the segmentation option for EPI images in SPM12. All<br>normalized data were denoised using ICA-AROMA<sup>32</sup>. Additionally, spatial smoothing was applied (8 millimeters)<br>to the EPI template and subsequently normalized and subsequently in Spatial smoothing was applied (8 millimeters)<br>to the fMRI data. As a further quality check of fMRI data, large head motion in any direction or rotation (> 3mm<br>or or 3°) was used as exclusion criteria in our study - no participants were excluded in this study. No global signal<br>regression was applied.<br>Based on the Harvard-Oxford<sup>33</sup> atlas, 111 regions of interest (ROI; 48 left and 48

or 3°) regression was applied.<br>Based on the Harvard-Oxford<sup>33</sup> atlas, 111 regions of interest (ROI; 48 left and 48 right cortical areas; 7 left and<br>right subcortical regions and 1 brainstem) were defined. In the Harvard-Ox regression was applied.<br>Based on the Harvard-O<br>right subcortical regions right subcortical regions and 1 brainstem) were defined. In the Harvard-Oxford atlas, brain areas were defined right subcortical regions and 1 brainstem) were defined. In the Harvard-Oxford atlas, brain areas were defined

using T1-weighted images of 21 healthy male and 16 healthy female subjects (ages 18-50). The T1-weighted images were segmented and affine-registered to MNI152 space using FLIRT (FSL), and the transforms were then applied t applied to the individual brain areas' labels. Finally, these were combined across subjects to form population<br>probability maps for each ROI<sup>33</sup>. For each ROI, a time-series was extracted by averaging across voxels per ti probability maps for each ROI<sup>33</sup>. For each ROI, a time-series was extracted by averaging across voxels per time<br>point. To facilitate statistical inference, data were "pre-whitened" by removing the estimated autocorrelati point. To facilitate statistical inference, data were "pre-whitened" by removing the estimated autocorrelation structure in a two-step generalized linear model (GLM) procedure<sup>34,35</sup>. In the first step, the raw data were structure in a two-step generalized linear model (GLM) procedure<sup>34,33</sup>. In the first step, the raw data were filtered against 6 motion parameters (3 translations and 3 rotations). Using the resulting residuals, the autoco filtered against structures present in the data were estimated using an Auto-Regressive model of orde<br>(AR(1)) and then removed from the raw data. Next, the realignment parameters, white matter (WM) are<br>cerebrospinal fluid  $(AR(1))$  and then removed from the raw data. Next, the realignment parameters, white matter (WM) and cerebrospinal fluid (CSF) signals were removed as confounders on the whitened data.

#### Local and global functional connectivity analysis

Eigenvector centrality mapping (ECM) is a measure to spatially characterize connectivity in functional brain imaging by attributing network properties to voxels<sup>26,36–38</sup>. The ECM method builds on the concept of eigenvector centrality, which characterizes functional networks active over time and attributes a voxel-wise centralit imaging by attributing network properties to voxels<sup>26,36</sup><sup>38</sup>. The ECM method builds on the concept of eigenvector centrality, which characterizes functional networks active over time and attributes a voxe<br>centrality valu eigenvector centrality, which characterizes functional network. In our study, fast ECM (fECM)<sup>39</sup> toolbox was used to estimate voxel-<br>wise eigenvector centralities (EC) from the time course data extracted based on the Harv neighbor ROI within a functional network. In our study, fast ECM (fECM)<sup>39</sup> toolbox was used to estimate voxel-<br>wise eigenvector centralities (EC) from the time course data extracted based on the Harvard-Oxford ROIs<br>defini We definition per subject. ECM is estimated from the adjacency matrix, which contains the pairwise correlation<br>between the ROIs. To obtain a real-valued EC value, we added +1 to the values in the adjacency matrix. Se<br>EC va between the ROIs. To obtain a real-valued EC value, we added +1 to the values in the adjacency matrix. Seve<br>EC values can be attributed to an individual node by the ECM method<sup>39</sup>, but only the eigenvector with the<br>highest EC values can be attributed to an individual node by the ECM method<sup>39</sup>, but only the eigenvector with the highest eigenvalue (EV) will be used for further analyzes for each node. The highest EV values were averaged acros highest eigenvalue (EV) will be used for further analyzes for each node. The highest EV values were averaged<br>across subjects at group level.<br><u>Functional connectivity (FC)</u> was computed for each participant applying the pai

Stadent t-test were used to examine differences in brain structural metrics and the post-Covid-1919-1919-1919-<br>between groups. between groups.

#### Permutation statistics

We quantify possible functional hubs by comparing the  $EC_{delta}$  (i.e., the difference in EC values pre- and post-COVID-19) values across groups using a family-wise error corrected (FWE) permutation test. Permuted labels based on group definitions (COVID + and COVID -) were repeated 1000 times per subject. Only ROIs with EC values that differ significantly were considered functional hubs. For both local and global functional connectivity analysis (EC and FC metrics), the FWE correction was applied for the number of group level comparisons and for the total number of ROIs analyzed. Linear regressions were applied to adjust for sex, years between pre- and post-COVID scans, and pre-COVID age. Only p-values adjusted and FWE corrected are reported.

#### Mediation analysis

To test the mediating role of brain metrics between COVID-19 and spatial working memory accounting for the longitudinal design of the study, a two-waves mediation analysis was applied (Figure 1, panel B)40,41. This extension of the traditional mediation analysis (Figure 1, panel A) accounts for longitudinal mediated effects of data<sup>40</sup>. A linear regression model was applied to test the effect of COVID-19 on the logit-transformed mediator<br>. (each brain area) measured at the second visit and adjusted for the baseline measurement. A negative binomial<br>and a linear regression were considered for the full models where the between errors and the strategy scores and a linear regression were considered for the full models where the between errors and the strategy scores (representing the SWM metrics) were considered as outcomes, respectively. Only brain areas identified as hubs in the permutation analysis and with significant association with COVID-19 were included in this analysis. Models were adjusted for sex, years between pre- and post-COVID scans and pre-COVID age. The statistical<br>significance level was set to 5% and all tests were two-sided. Statistical analyses were performed using R  $s$ ignificance level was set to 5% and all tests were two-sided. Statistical analyses were performed using R (Version 4.3.1), the mediation analysis was conducted using the mediation<sup>+2</sup> R package (Version 4.5.0).

Figure 2 - Schematic depicting mediation models used. A. Classical mediation and regression models. The objective of the media ation analysis was to determine if the indirect effect (path a\*b) was different from zero, suggesting that the mediating variable (i.e., brain

metrics) altered the strength of the relationship between X and Y (i.e., COVID-19 status and spatial working memory metrics). Three linear regression equations were used to assess the mediation in the traditional cross sectional experimental design: Y regressed on X,<br>M regressed on X, and Y regressed on both X and M . The letters a, b, c, and c' refer respective model, with e representing the error term. B. Given the longitudinal design of our study, we extended the traditional respective model, with e representing the error term. B. Given the longitudinal design of our study, we extended the traditional mediation analysis presented in panel A using a pre- and post-test control group design. Diagram includes: the pre-test covariance between mediator (M<sub>pre</sub>) and dependent variable (Y<sub>pre</sub>), σ<sub>MpreYpre</sub>; the effect of the mediator measured pre-COVID (M<sub>pre</sub>) on the mediator measured post-COVID (M<sub>post</sub>) (stability of mediator s<sub>MpreMpost</sub>); effect of the outcome measured pre-COVID (Y<sub>pre</sub>) on the outcome measured post-COVID (Y<sub>post</sub>) (stability of outcome s<sub>YpreYpost</sub>); the effect of M<sub>pre</sub> on Y<sub>post</sub> (cross-lagged relation, b<sub>MpreYpost</sub>); the effect of X on  $M_{post}$ , a<sub>MpostX</sub>; the effect of X on Y<sub>post</sub>, c'<sub>YpostX</sub>; and the effect of  $M_{post}$  on Y<sub>post</sub>, b<sub>MpostYpost</sub>.

Table 1 - Sociodemographic and clinical characteristics of PHIME-COVID participants who were selected for the current study (N=40).

Note: Mean, standard deviation (sd), range (minimum and maximum values), and percentage (%) are reported. P-values were derived using Student's t-tests and Wilcoxon rank sum test for continuous variables (if the variables of OND) -<br>Bireline-d'exemployee was not included was not to be also and the variable was not included was normally distributed or not, respectively) and tests for categorical variables to assess the differences between COVID+ and COVID-.

\*COVID-PHIME participants reported mild-COVID symptoms. These participants reported symptoms outside of the 12 months threshold used to define COVID positivity.

Structural and functional differences between COVID+ and COVID-

EC values in permutation tests (COVID+ vs. COVID-) revealed five functional hubs where ECdelta values differed significantly between COVID+ and COVID- groups including: right intracalcarine cortex, right lingual gyrus, left hippocampus, left amygdala, and left frontal orbital cortex (Table 2, Figure 3A and 3B).

Figure 3 - Functional hubs differ in EC<sub>delta</sub> between COVID+ and COVID- participants. Panel A reports the identified ROI for which EC<sub>delta</sub> (differences in eigenvector centrality (EC) between pre- and post-COVID) differed significantly between PHIME<br>participants with and without COVID-19 (i.e., functional hubs). Panel B reports the average EC<sub></sub> participants with and without COVID-19 (i.e., functional hubs). Panel B reports the average ECdelta values for each functional hub identified. Blue bars indicate EC values of COVID+ participants, while orange bars indicate COVID- participants.

Table 2 - Statistical differences in ECdelta values between COVID+ and COVID- participants.

J Table 2 reports the full name of the brain regions interest (ROIs), ROI's hemisphere, ROI's abbreviation and p-values of the identified ROIs for which EC<sub>delta</sub> differed significantly between PHIME participants with and without COVID-19 (i.e., functional hubs). Only p-values FWE corrected, adjusted for sex, years between scans and age at the first visit (pre-COVID) are reported.

For brain areas identified as functional hubs, structural differences between groups were investigated using volumetric values adjusted for TIV (Table 3, Figure 4). Only the left hippocampal volume was reduced in COVID+ compared to healthy participants (p=0.034, Table 4).

We also compared whole brain connectivity between COVID+ and healthy participants by plotting the averaged<br>FC scores across all ROIs pre- and post-COVID and the difference in functional connectivity metric between pre-FC scores across all ROIs pre- and post-COVID and the difference in functional connectivity metric between preand post-COVID (Figure S1, supplementary material). No significant differences were found (FCdelta p= 0.786).

 $\overline{\phantom{a}}$ Figure 4 - Volumetric difference in the hippocampus between COVID+ and COVID- participants. The left hippocampal Volumetricdelta (difference in volumetric metrics between pre- and post-COVID) statistically differs between PHIME participants with and without COVID-19. The blue box indicates volumetric values of COVID+ participants, while the orange box indicates volumetric values of COVID- participants. Black lines indicate the median value.

 Table 3 - Statistical differences in Volumetricdelta between COVID+ and COVID- participants.

Table 3 reports the statistical differences in Volumetric<sub>delta</sub> (difference in volumetric metrics between pre- and post-COVID) Table 3 reports the statistical differences in Volumetricdelta (difference in volumetric metrics between pre- and post-COVID) between PHIME participants with and without COVID-19. Only brain areas that are previously identified as functional hubs (i.e., brain areas for which EC<sub>delta</sub> differed significantly between PHIME participants with and without COVID-19) are included in this analysis. The table reports the full name of the brain regions interest (ROIs), ROI's hemisphere and p-values. Only p-values adjusted for sex, years between scans, age at the first visit (pre-COVID) and total intracranial volume are reported.

#### Mediation analysis

l, We observed significant associations between COVID-19 status and brain metrics in only one of the five functional hubs; the left amygdala (p-values for interaction= 0.032). Mediation analyses were performed to quantify possible indirect effects of the brain on the association between COVID-19 and spatial working memory in the functional hubs significantly associated with COVID-19. Results indicate that the left amygdala mediated the association between COVID-19 and SWM "between errors" (p-values for indirect effect= 0.028). No significant associations were found for SWM "strategy" SWM.

Table 4 – Two-waves mediation analysis of the effect of COVID-19 on the cognitive scores (between errors and strategy metric obtained from SWM test) considering the brain area selected as functional hub (EC values) as mediators.

Two-waves mediation analysis performed to assess the direct, indirect and total effects of COVID-19 on SWM. EC brain values at baseline (pre-COVID), sex, years between pre- and post-COVID scans, pre-COVID age and SWM at baseline were<br>used as covariates in the models. Only brain areas identified as hubs in permutation analyzes were entere used as covariates in the models. Only brain areas identified as hubs in permutation analyzes were entered as outcomes in this analysis. Then mediation analyses were performed using a pre-post test design. The moderating effects of brain metrics (eigenvector centrality value of a single brain area defined using the Harvard-Oxford atlas between COVID-19 and cognitive domains, in this case SWM.

## Discussion

### Supplementary Materials

Figure S1 - Whole brain functional connectivity matrices, based on the Harvard-Oxford atlas. For each timepoint, first all individual functional connectivity (FC) matrices were calculated by applying Fisher's r-to-z transformation, which were then averaged across participants. Panels a, b, c and d show the mean inter-ROI correlation matrices for pre-COVID (baseline), post-COVID and estimated FC<sub>delta</sub>(i.e., the difference in FC values pre- and post-COVID-19), respectively.

Table S1 - COVID symptoms reported by COVID+ participants.

Note: Number of subjects and percentage (%) are reported for COVID+ participants.
