32 **ABSTRACT**

33 **Introduction:** Health risk assessment (HRA) strategies are cornerstone for health systems transformation
34 toward value-based patient-centred care. However, steps for HRA adoption are undefined. This report
35 analyses the process of transference of the Adjusted Morbidity Groups (AMG) algorithm from the Catalan
36 Good Practice to the Marche region (IT) and to Viljandi Hospital (EE), within the JADECARE initiative
37 (2020-2023).

38 **Description:** The implementation research approach involved a twelve-month pre-implementation period
39 to assess feasibility and define the local action plans, followed by a sixteen-month implementation phase.
40 During the two periods, a well-defined combination of experience-based co-design and quality
41 improvement methodologies were applied.

42 **Discussion:** The evolution of the Catalan HRA strategy (2010-2023) illustrates its potential for health
43 systems transformation, as well as its transferability. The main barriers and facilitators for HRA adoption
44 were identified. The report proposes a set of key steps to facilitate site customized deployment of HRA
45 contributing to define a roadmap to foster large-scale adoption across Europe.

46 **Conclusions:** Successful adoption of the AMG algorithm was achieved in the two sites confirming
47 transferability. Marche identified the key requirements for a population-based HRA strategy, whereas
48 Viljandi Hospital proved its potential for clinical use paving the way toward value-based healthcare
49 strategies.

50

51 **Key words:** Health Risk Assessment, Adjusted Morbidity Groups, Integrated Care, Predictive modelling.

52 BACKGROUND & OBJECTIVES

53 Health risk assessment (HRA) is a comprehensive approach that entails identifying, evaluating, and
54 prioritising potential health risks and vulnerabilities for individuals and populations and identifying
55 possible measures to reduce or mitigate their effects.

56 Deploying appropriate HRA strategies is a cornerstone for population risk stratification and constructing
57 the corresponding population risk pyramid. It has become essential for informing health policy decisions,
58 allocating resources, benchmarking, implementing preventive strategies and selecting appropriate
59 healthcare services(1–3). Likewise, in the clinical arena, HRA is a building block for generating predictive
60 models to support clinical decision-making(4,5). Indeed, population-based, and clinically-oriented HRA
61 approaches are complementary elements needed to efficiently adopt integrated patient-centred care
62 strategies. Deploying and adopting well-planned HRA strategies constitute an obligatory step toward the
63 maturity of precision medicine(6).

64 Moreover, the momentum propitiated by the continuous progress in digital technologies for data capture
65 and management, artificial intelligence and the advances in medical sciences are shaping novel and
66 stimulating scenarios for health promotion and care and positioning predictive medicine at the
67 forefront(7–9). Despite the promising potential of HRA, there is a noticeable gap between its benefits and
68 its current application, attributed to several limitations, including the utilisation of suboptimal risk
69 assessment tools, the insufficient engagement of health professionals, the application of ineffective or
70 inexistent deployment strategies, and unresolved ethical and regulatory issues(10,11).

71 The Joint Action on implementation of digitally enabled integrated person-centred care (JADECARE)(12),
72 an ongoing initiative launched to face the challenges of the transformation of health in the European
73 Union, has included HRA as a strategic block to transfer from four original Good Practices (oGPs) to other
74 twenty-one European regions participating as Next Adopters (NAs).

75 The central aims of JADECARE are to reinforce the capacity of health authorities for successfully
76 addressing all the crucial aspects of health system transformation, in particular, the transition to digitally
77 enabled, integrated, person-centred care, and to support the best practice transfer from the oGPs to the
78 corresponding NAs. The current integrated case reports:

- 79 1) The evolution of the HRA strategy in one of the JADECARE oGPs (i.e., Catalonia, ES) from 2011-2020.
- 80 2) The description of the implementation process followed to transfer a population-based risk
81 assessment tool from Catalonia to two NAs: Marche region (IT) and Estonia (EE).
- 82 3) The lessons learnt in the form of recommendations to foster the adoption of enhanced health risk
83 assessment across the EU.

84 The report aims to identify key barriers and facilitators for effective adoption across Europe of
85 population-based health risk assessment at the regional/country levels and formulate proposals
86 facilitating the articulation between population-based and clinically-oriented HRA.

87

88 **DESCRIPTION OF THE CARE PRACTICE**

89 **HRA IN CATALONIA: 2011-2020**

90 The 2011-2015 Catalan Health Plan(13) fostered key achievements in digital health transformation, the
91 progressive implementation of person-centred integrated care services and the adoption of an initial
92 population-based HRA strategy. This transitory HRA strategy was based on the commercial solution
93 “Clinical Risk Groups” (CRG)(14) from vendor 3M™ and oriented toward modelling healthcare costs for
94 resource allocation and benchmarking.

95 This initial HRA strategy laid the groundwork for a population-based risk stratification program with a
96 case-finding approach focused on preventing adverse health events, managing high-risk chronic patients,
97 and early detecting end-of-life patients(15,16). This HRA approach acknowledged the close relationship
98 between frailty and multimorbidity while recognizing their distinct nature as independent risk factors.
99 Additionally, it introduced specific scales for the evaluation of each factor individually. The clinical
100 complexity level was assigned based on multimorbidity scoring, transitively using CRGs, and the clinical
101 judgment of primary care physicians. Complex patients were classified into two groups: complex chronic
102 patients (CCP), approximately 4% of the population, and advanced chronic patients (ACP), representing
103 approximately 1% of the population with limited life expectancy. Specific community-based management
104 plans, aiming at integrating health and social care, were defined for these two categories of patients(15).
105 An overall description of the care model for people with frailty and multimorbidity in Catalonia, tested
106 during the 2011-2015 Health Plan, has been recently reported in (17).

107 The need for refining the assessment of the multimorbidity burden triggered the creation of the Adjusted
108 Morbidity Groups (AMG)(18,19), a new morbidity grouper that reflects patients’ disease burden in terms
109 of the number and complexity of concomitant disorders through a disease-specific weighting deduced
110 from statistical analysis based on mortality and the utilisation of healthcare resources. The AMG tool was
111 jointly launched in 2015 by the Spanish Health Ministry and the Catalan public health commissioner
112 (CatSalut). A significant achievement was the development of a dashboard to monitor the population's
113 multimorbidity burden and the use of healthcare known as Modules for Monitoring Quality Indicators
114 (“Moduls pel Seguiment d’Indicadors de Qualitat”, MSIQ)(20), which generates and displays customised
115 key performance indicators (KPIs) with aggregated data to inform health policy decisions, benchmarking,

116 and governance. On the clinical side, the AMG scoring of the patient is currently displayed in the
 117 workstation of the primary care physicians and the shared clinical history(21) as a support tool in the
 118 clinical setting.

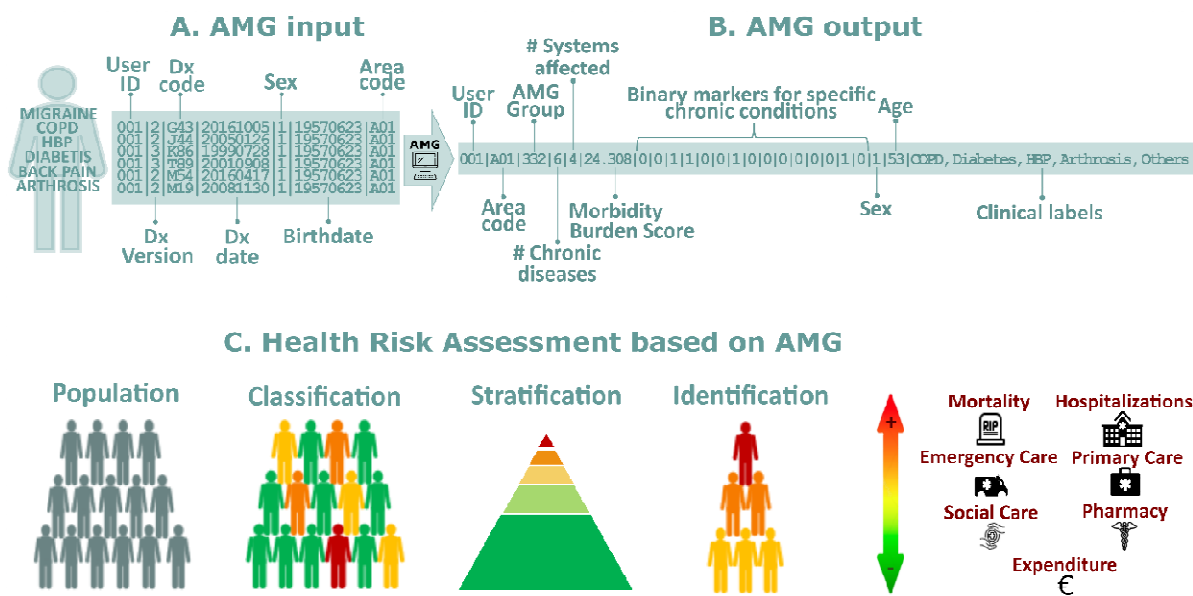

119 During the 2016-2020 Catalan Health Plan(22), the utilisation of AMG for HRA purposes was validated in
 120 different regions of Spain, covering a population of approximately 38 million citizens and showing good
 121 transferability in all cases(23). This period witnessed three significant advancements in Catalonia's HRA
 122 strategy:

123 1) The execution of several studies testing the contribution of the AMG in different HRA settings, such as
 124 the identified risk factors during the SARS-CoV-2 pandemic(24,25), the refinement of tools for resources
 125 allocation(26–29), the analysis of the effect of the multimorbidity burden in patients with chronic
 126 obstructive pulmonary disease (COPD)(30), and assessing the use of AMG in complex clinical predictive
 127 models for short-term clinical outcomes predictions after hospital discharge(4,5).

128 2) The creation of the Catalan Health Information System Master Plan published in 2019(31) established
 129 the basis for the transformation to a new digital-health paradigm based on a knowledge-driven platform
 130 and adopting the Open-EHR standard as a reference.

131 3) The development and internal validation of the Queralt indices(32,33) to characterise the complexity
 132 of hospitalisation episodes, combining information on the principal discharge diagnosis, pre-existing
 133 comorbidities, in-hospital complications and all the procedures performed during hospitalisation.

134 **Figure 1** depicts the information required from NAs to use the AMG, the outputs obtained, and the key
 135 uses of AMG.

136

137 **Figure 1- Panel A - AMG input:** Required input variables to compute AMG; **Panel B – AMG output:** Output variables of the AMG
138 algorithm. *Binary markers (presence/absence) of 15 chronic conditions (from left to right): diabetes mellitus, heart failure,
139 chronic obstructive pulmonary disease, high blood pressure, depression, HIV/AIDS, chronic ischemic heart disease, stroke, chronic
140 kidney disease, cirrhosis, osteoporosis, arthrosis, arthritis, dementia, chronic pain; **Panel C– Health Risk Assessment based on**
141 **AMG:** The AMG scoring allows for three key actions: **Classification:** The population is categorised into specific groups based on
142 their morbidity statuses, such as healthy, pregnancy and labour, acute disease, chronic disease in 1-4 systems, or active neoplasia,
143 which are also divided into five degrees of severity. **Stratification:** Each individual can be assigned a complexity score that reflects
144 the care needs that people may have based on their health problems. **Identification:** Individuals with specific major chronic health
145 problems can be identified, which helps track people with more complex care needs.

146

147 **PRE-IMPLEMENTATION (October 2020 – September 2021)**

148 Within JADECARE, the AMG was transferred to the Marche region and Estonia. The Marche region has a
149 regionally based healthcare system, providing universal coverage to 1,480,839 citizens of which 25.4% are
150 65 years and older. Life expectancy is of 81 years for men and 85.2 for women. In comparison, Estonia has
151 compulsory solidarity-based health insurance, financed by the health insurance budget through the
152 Estonian Health Insurance Fund, covering 1,322,765 citizens, 29.0% aged 65 years and older. Life
153 expectancy at birth is 72.8 years for men and 81.4 for women.

154 In Estonia, the initial implementation site for the AMG transfer was chosen was Viljandi County with
155 approximately 30 general practitioners and one general hospital providing specialist care for around
156 50,000 inhabitants.

157 **Table 1** describes the context and the trigger that motivated the adoption of the AMG in the Marche
158 region and Estonia, alongside the local aims of each NA and the main challenges identified by the oGP
159 leaders. Specific Local Action Plans were designed to fulfil the needs of each NA, as reported in detail in
160 the **Supplementary Material**. The pre-implementation phase concluded once the implementation
161 feasibility study was successful in each site.

162 **Table 1 - Summary of the pre-implementation process, including the context and trigger, the aims, the**
 163 **baseline situation, and the challenges faced in the Marche region and Estonia.**

| | Marche region | Estonia |
|----------------------------|---|--|
| Context and trigger | <p>1) The high burden of non-communicable diseases (NCDs) and the need for more efficient management of affected patients.</p> <p>2) The need for support decision-making in healthcare services and policies and analyse the utilisation of healthcare resources in alignment with national regulations defining population stratification as a prerequisite for healthcare planning (e.g. National Plan for Chronicity, 2016; National Decree on standards and organisation of community services, 2022).</p> | <p>1) Digital infrastructure to support integrated care was piloted in Estonia with minimal impact and long-term traction, and there was not yet region-wide coverage. Likewise, social and healthcare service coordination is in an early phase.</p> <p>2) The different and non-aligned payment schemes for hospital and ambulatory care impact incentivising the transformation from case-based care to a population health-oriented care model with social services integration to care.</p> <p>3) Risk stratification and case-finding tools were needed to facilitate high-risk patient identification for regional care-management and service integration.</p> |
| Aims | <p>1) To test and adopt the AMG population stratification algorithm, suitably adapted to the regional context and the available health data.</p> <p>2) To display a regional dashboard for health policy purposes, benchmarking, and decision-making processes.</p> | <p>1) To develop an integrated clinical program to prevent hospitalisations and target elders with concomitant chronic diseases and social health determinants.</p> <p>2) To adopt the AMG for service selection.</p> <p>3) To leverage the acquired expertise and progress towards innovative value-based reimbursement models, aiming to establish Viljandi Hospital as an accountable care organization.</p> <p>4) To escalate the adoption of AMG for population stratification at country-level.</p> |
| Baseline situation | <p>The Regional Healthcare Administrative Databases (HADs), used at regional and national levels to monitor healthcare system expenditures and performance, gather information on healthcare services provided to citizens (e.g., hospitalisations, emergency-urgency, homecare, exemption codes, etc.). Common standard models and coding systems, such as DRGs(34) and ICD-9-CM(35), are used across all regions. However, each HAD has its unique structure, unit level, content, and rules for data input. Data linkage across HADs is facilitated using a unique anonymised patient ID code.</p> | <p>The Estonian Health Insurance Fund claims database was used for model data input. In Estonian universal healthcare and single payer model this database entails almost all medical care claims in the country. The database follows a single standard with ICD-10-CM(36) coding, DRGs. Data linkage and access was granted though ethics committee approval and is not easily available as standard. Data was analysed in anonymised format using unique patient ID codes. All AMG analyses were performed by the regional medical authorities under the ethics committee approved application with support from the oGP.</p> |
| Challenges | <p>1) To fulfil the initial feasibility test.</p> <p>2) To overcome potential technical problems in dynamically assembling the dataset required to feed the AMG algorithm using heterogeneous data sources.</p> <p>3) The site showed an explicit limitation in the use of HRA tools due to the GDPR-related legislation at the Italian level regarding the secondary use of health data.</p> | <p>1) To fulfil the feasibility test.</p> <p>2) To ensure firm commitments of the Estonian government (Ministry of Social Affairs), as well as getting traction and commitment by the Estonian Health Insurance Fund to the project.</p> <p>3) To overcome potential technical problems in dynamically assembling the dataset required to feed computational modelling for health risk stratification.</p> |

164

165 Results of the feasibility analysis

166 To assess the transferability of the AMG tool, independent feasibility tests were conducted in each of the
167 adopting regions. To perform the AMG feasibility analysis in the Marche region, fully anonymized
168 information on disease diagnostics from 2015 to 2019 was extracted from three independent databases:
169 the hospital admissions, the emergency department, and the exemption codes for chronic and rare
170 diseases databases. Integrating all the medical information resulted in 5,939,199 diagnostic codes
171 associated with 1,367,181 citizens. In Estonia, the AMG feasibility study was conducted with 25,930
172 diagnostic codes related to 4,765 citizens treated in Viljandi Hospital in 2018.

173 The feasibility analysis evaluated the comprehensiveness of the clinical information accessed and the
174 discrimination capacity of the AMG algorithm to identify high-risk individuals allocated in seven morbidity
175 groups: healthy, pregnancy, acute disease, 1 or 2-3 or ≥ 4 chronic diseases, and active neoplasia.

176 When evaluating the feasibility study, it is imperative to consider the databases' dual approach and
177 purpose. The Marche database is a population health database(37), built for informing health policies,
178 benchmarking, and supporting decision-making processes. On the other hand, the Viljandi database
179 follows a population medicine approach(37), assembling patient registries to screen candidates for a
180 clinical program geared towards preventing hospitalisations for elderly patients with concomitant chronic
181 conditions.

182 The feasibility tests were deemed successful if the following conditions were met:

183 1)The algorithm effectively discriminated the patients with different risk profiles within specific age and
184 gender groups, especially in older individuals more susceptible to multimorbidity.

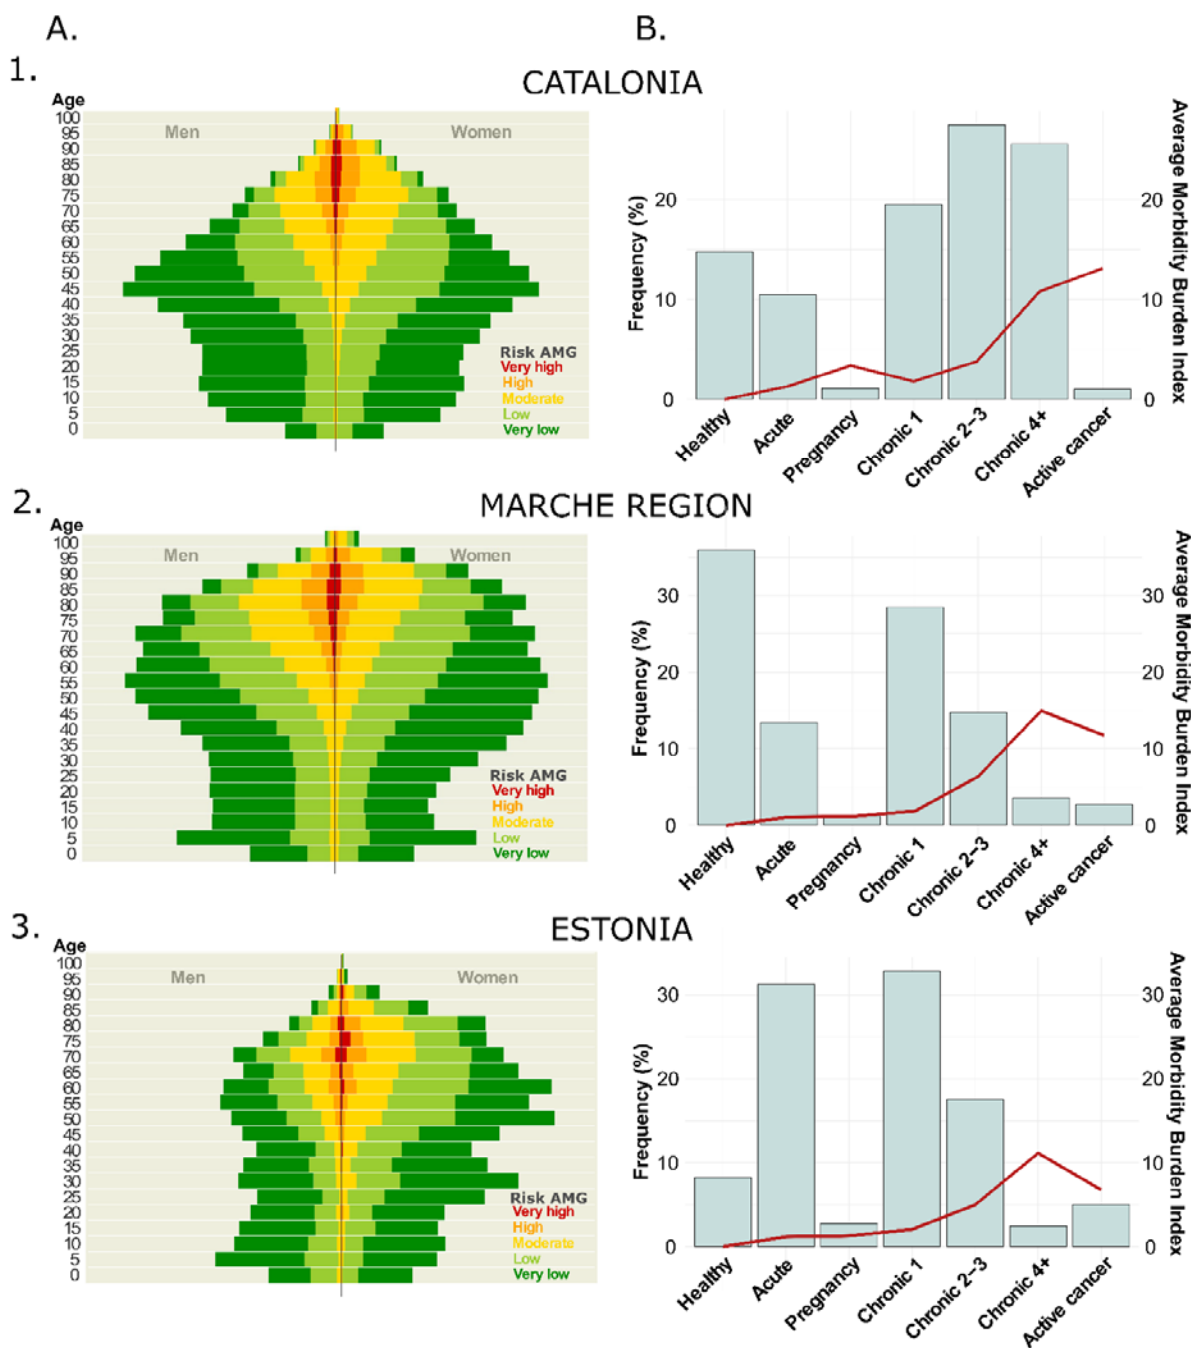

185 2)The algorithm distinguished between the seven AMG disease groups. It's worth noting that the relative
186 frequencies of these groups may differ depending on the database's nature.

187 3)The results showed a positive correlation between the clinical complexity of the AMG disease groups
188 and the disease burden evaluated using the AMG Morbidity Burden Index.

189 The feasibility analysis results are shown in **Figure 2**. In **Panel A**, the distribution of the five subgroups of
190 complexity is depicted according to age and gender. As expected, the demographic characteristics of the
191 population treated in Viljandi utilised in this feasibility study differ from the Viljandi county's population.
192 Overall, the AMG algorithm proficiently distinguished patients with varying risk profiles in specific age and
193 gender categories. **Panel B** shows the distribution of the seven AMG morbidity groups' complexity level,
194 represented by the average Morbidity Burden Score. In the Marche region and Estonia, roughly 50% of
195 the population suffers at least one chronic disease and 20% developed multimorbidity, while 5% has an

196 active neoplasm. Notably, the analysis of the population treated in Viljandi Hospital revealed a higher
197 fraction of citizens with acute morbid conditions due to the hospital nature of the database. When
198 comparing the relative distribution of AMG disease groups between the adopting regions and Catalonia,
199 notable disparities emerge in terms of the prevalence of patients with multimorbidity. These variations
200 can be attributed to the availability of primary care registries, which is a condition exclusively fulfilled in
201 the Catalan context. This underscores the critical importance of integrating health data from diverse
202 levels. The complexity of the disease groups and the AMG Morbidity Burden Score showed a strong
203 positive correlation, being slightly higher in the Marche region due to the exhaustivity of the diagnostic
204 records at different healthcare levels and the increased length of the study period.

205 Based on the assessment made by the oGP specialists and the findings presented, it was determined that
206 the databases generated by both adopters, the Marche region and Estonia, were mature and ready to
207 expedite the implementation of the AMG.

208

209 **Figure 2- Results of the feasibility analysis:** in Catalonia (1) and the adoption regions, Marche Region (2) and Estonia (3). **Panel A**
 210 **- AMG risk distribution:** itemised by age and gender; **Panel B – AMG disease groups:** distribution of the seven AMG morbidity
 211 groups (bars): healthy, pregnancy, acute disease, 1 or 2-3 or ≥ 4 chronic diseases, and active neoplasia, and their average
 212 Morbidity Burden Score (line).

213 **IMPLEMENTATION (October 2021-January 2023)**

214 On October 2021, the Local Action Plans (LAPs) in Marche and Estonia were already available, and the
 215 corresponding NA Working Groups were prepared to undertake two Plan-Do-Study-Act (PDSA) cycles(38).

216 The details of the PDSA cycles are reported in the **Supplementary Material**. A major midterm milestone
217 of the implementation phase was the HRA Thematic Workshop, held in Viljandi Hospital on 14-15 June
218 2022. The workshop delimited the bases for deploying population-based HRA strategies focused on
219 AMG and the Queralt indices. A recording of the session can be found in the **Supplementary Material**.

220 **Marche**

221 **Implementation achievements** - 1) dynamic regional dataset preparation merging information from
222 different existing data sources, 2) data cleaning and automatization of the generation of the regional
223 dataset, 3) elaboration and analysis of the risk assessment pyramid at regional level demonstrating
224 association between GMA scoring and local use of resources, 4) preparation of the logistics for local
225 sustainability of the setting; and 5) design of the regional dashboard to facilitate regional health
226 governance. The technicalities of the implementation and the assessment of the implementation process
227 will be reported in a forthcoming paper.

228 **Sustainability Action Plan** - 1) to complete the integration of the tool into the regional IT infrastructure,
229 adding further healthcare databases and defining supportive actions to improve the quality and
230 completeness of healthcare data. 2) to implement the dashboard in computational, technical, and
231 graphical terms, adding maps aimed to visualize healthcare services adjusted to social-health care
232 planning regulations and integrating it in the regional IT infrastructure. 3) to promote the use of the HRA
233 tools by regional and clinical managers and share our experience for the discussions on the secondary use
234 of health data.

235 **Estonia**

236 **Implementation achievements** – 1) Generating a protocol, already approved by the local Ethics
237 committee for a pragmatic randomized control trial (n= 1000), to test effectiveness and value generation
238 of an integrated care intervention to prevent hospitalizations targeting community-based patients with
239 high-risk of admissions and enhancing transitional care post-discharge to reduce early readmissions (PAIK
240 2022-2025). 2) AMG will be used as inclusion criteria and to modulate the characteristics of the
241 intervention and the Queralt indices will be employed to characterize hospitalization episodes
242 contributing to personalize transitional care after discharge.

243 **Sustainability Action Plan** - 1) to successfully execute the PAIK 2022-2025 project using AMG and Queralt
244 indices as risk assessment tools.2) to generate sound proposals for innovative reimbursement
245 modalities.3) to achieve country-wide scalability of risk prediction approaches based on AMG and
246 Queralt.4) to initiate a debate on the scalability of integrated care services involving innovative
247 reimbursement modalities in Estonia.

248 **PERSPECTIVES BEYOND IMPLEMENTATION**

249 The section describes the status of the HRA in Catalonia and briefly reports the overarching analysis of the
250 process of transference to the two NAs, leading to recommendations for the generalisation of the case
251 practice at the European level.

252 **Evolution of the Catalan oGP during JADECARE**

253 The 2020 Catalan Health Information System Master Plan has sparked ongoing technological innovations
254 that offer significant opportunities in predictive modelling aiming at supporting clinical decision-making
255 for healthcare professionals and provide patients with decision support tools to empower self-
256 management(39–41) . Also, specific initiatives have been launched to enhance transitional care and
257 reduce early readmissions after hospital discharge(4,5). Moreover, efforts are devoted to the practicalities
258 of adoption of such predictive modelling tools in real-world settings, involving: 1) training and continuous
259 evaluation of clinical decision support systems embedded into integrated care services, 2) pragmatic use
260 of implementation science tools to foster engagement of health professionals, and 3) ethical and
261 regulatory aspects including refinement of the regional PADRIS program(42) for secondary use of health
262 data.

263 In Catalonia, research, and innovation in HRA are currently focused on two target areas. Firstly, to address
264 unmet needs associated with enhanced predictive modelling considering four potential sources of
265 variables: 1) clinical information, 2) registry data with a population health approach, 3) patients' self-
266 reported information (PROMs and PREMs) and self-monitoring data, and 4) biomedical research data, as
267 defined in (1). A key learning from the different studies done using the AMG algorithm since 2015 is that
268 multimorbidity has a central explanatory role in health risk assessment, more than classical variables like
269 age, which prompts the inclusion of the AMG scoring as a fix covariate in multisource predictive
270 modelling.

271 A second field of research interest is the potential evolutions of AMG incorporating information on
272 patients' disease trajectories(43,44). Although these novel computational developments are still far from
273 being applicable in clinical settings, they present exciting prospects or precision medicine in patients with
274 NCDs.

275 **Overarching analysis**

276 The case practice identifies the process of transference and adoption of the AMG algorithm and a site-
277 tailored dashboard using aggregated data as the two key components necessary for establishing
278 fundamental HRA functionalities.

279 While Marche adopted a population-health approach considering the use of healthcare resources from
280 the entire geographical area, Viljandi Hospital in Estonia implemented a more limited regional population-
281 medicine orientation with a single hospital as a local integrator and lead in a regional health improvement
282 initiative. As depicted in **Figure 2**, the differences in terms of sources and composition of input data had
283 significant impacts on the distribution of AMG scoring among Catalonia (**Figure 2 - Panel 1**, population-
284 health data from all healthcare tiers), Marche (**Figure 2 - Panel 2**, population-health data with poor
285 representation of primary care) and Viljandi Hospital (**Figure 2 - Panel 3**, population-medicine approach
286 based on hospital information). Accordingly, population-health databases, as those used in Marche
287 region, must comprise information on disease diagnostics from all individuals within the region, gathered
288 from various tiers of the healthcare system (e.g. primary care, community, hospital, etc.). It is expected to
289 find a significant fraction of the healthy population and cases with transitory health problems, both
290 concentrated in the youngest fraction of the population. The remaining population is expected to suffer at
291 least chronicity and many of them to develop multimorbidity; among them is expected to find a small
292 fraction of complex chronic patients.

293 On the other hand, if the analysis is conducted following a population medicine approach, as done in
294 Viljandi, the sample should be representative of the population treated at the hospital during the period
295 assessed, both in terms of demographic parameters and the clinical profiles of the patients. In light of
296 this, a highly biased population is expected to be older than the hospital's catching area average. Also, a
297 substantial increase in the frequency of patients experiencing mainly acute and chronic conditions is
298 anticipated.

299 Consequently, the composition of the input datasets plays a crucial role in modulating both purposes and
300 suitability of adopting HRA strategies. In the current case practice, Marche's approach was adequate to
301 cover health policy aspects, resources allocation, benchmarking, and governance at the regional level,
302 even though limitations due to GDPR constraints at the Italian level should be acknowledged. In contrast,
303 the HRA orientation adopted by Viljandi Hospital was beneficial in the design process of the PAIK2
304 protocol (2023-2025), aiming at generating evidence of the effectiveness of an integrated care
305 intervention to prevent hospitalisations in high-risk patients and transitional care. It is of note that the
306 process of developing the case practice in the two sites has generated knowledge and skills that will be
307 needed to elaborate future site-customised comprehensive HRA strategies, as described in the case of
308 Catalonia.

309 In summary, the essential maturity requirements for sustainable HRA strategies are: 1) to achieve solid
310 political commitment at the regional/country level fostering necessary interactions, top-down and
311 bottom-up, among key stakeholders; 2) to have an essential digital maturity at the site level to

312 satisfactorily pass the feasibility analysis; 3) to overcome potential limitations due to local application of
313 GDPR; 4) to use highly applicable implementation science tools fostering engagement of all stakeholders,
314 health policy managers and health professionals, during the process elaboration and deployment of the
315 local HRA strategy; and 5) to develop/adopt a regulatory framework for secondary use of health data,
316 needed for business intelligence and the elaboration of computational modelling for clinical
317 applications. **Table 2** depicts the steps identified during the transference process to define a roadmap for
318 adopting site-customised HRA strategies.

319 Moreover, using the HRA tools described in the case practice as open-source software and articulating
320 public-private collaborations supporting productive interactions and networking among sites are essential
321 to speed up transferability and large-scale adoption of HRA strategies at the European level.

322 **Table 2 – Checklist of key steps for site adoption of Health Risk Assessment (HRA)**

| Key steps | Description |
|--|---|
| 1.Scope definition | Identify the purpose, focus/use and ambition of the HRA initiative |
| 2.Source population | Population-health or Population-medicine. For each option, identify specificities of the source population |
| 3.Planned updates | Periodicity of source data update (i.e. yearly basis) |
| 4.Model (Morbidity grouper) | Morbidity grouper selected: AMG, CRG, ACG, others |
| 5.Input variables (Fig. 1) | Minimum variables of the morbidity grouper plus additional variables selected for inclusion in the HRA modelling. |
| 6.Data source(s) <i>(data sources and ownership have technical/managerial implications)</i> | <ol style="list-style-type: none"> 1. Input data are extracted from one owned data source 2. Input data are extracted from different owned data sources 3. Input data are extracted from one data set source not owned 4. Input data are extracted from several data sets not owned |
| 7. Predictive modelling | Identify statistical methods, Machine Learning, Deep Learning, etc... |
| 8. Output variables (Fig 1) | Variables generated by the predictive modelling approach |
| 9. Feasibility assessment | Includes characterization of site maturity and preliminary testing of the HRA tools to ensure minimum quality before implementation |
| 10. Technological logistics | The complexity of the digital setting is closely related to the characteristics of the data sources and ambition of the HRA strategy. It requires assessment of sustainability over time in terms of technological and human resources. |
| 11. Initial assessment of the core predictive modelling | Quality assessment to be carried out immediately after deployment to define further steps leading to a sustainable HRA program |
| 12. Quality assurance program | Continuous quality assurance checking of the HRA program after sustainable adoption |
| 13.Dashboard preparation | Initial identification of key performance indicators (KPIs) to be monitored after adoption, as well as subsequent enrichment of the dashboard with novel KPIs as required. |
| 14. Stakeholders' engagement | Highly applicable implementation research tools in place to foster engagement of users. The professional profiles will depend on the focus of HRA: policy makers, managers, clinical professionals, etc... |
| 15. Additional functionalities & Roadmap for further developments | Successful HRA adoption leads to initiatives to expand use and ambition requiring development of additional functionalities (predictive modelling) and definition of a roadmap for further developments either in the health policy area, management, clinical applications and/or research-innovation. |

324 DISCUSSION

325 The current report is filling an existing gap in information on building up an HRA strategy at the
326 regional/country level, as described for Catalonia, and its potential for transferability to other sites.
327 Moreover, the Marche and Viljandi Hospital process generated a helpful checklist for generalising such
328 transference to other sites across Europe.

329 The case practice has also recognised the convenience of further collaboration among regions beyond
330 JADECARE to keep progressing toward mature HRA strategies contributing to paving the way for precision
331 medicine. Moreover, the use of the current and future available algorithms (i.e. AMG, Queralt, etc.), and
332 dashboards, as open-source software, as well as the provision of consultancy services supporting future
333 next adopters, were identified as core elements to foster the adoption of efficient HRA strategies across
334 Europe. To this end, the elaboration of a survey to be administered to all JADECARE's sites is strongly
335 encouraged. The main aim is characterising the status and needs of all NAs regarding HRA. The
336 information from the survey gathered before the project end can contribute to refining a large-scale
337 implementation protocol to be customised at the site level beyond the project lifetime.

338

339 LESSONS LEARNED

340 The analysis of the HRA strategies in Catalonia (2010-2023), as well as the process of transference and
341 adoption of the AMG in Marche (IT) and Viljandi Hospital (EE) within JADECARE, 2020-2023, generated the
342 following key learnings aiming at fostering large-scale adoption of HRA across Europe:

343 *1. Adopting comprehensive HRA strategies, including multimorbidity weight (AMG scoring) as a*
344 *central component, constitutes a key element fostering health systems transformation toward value-*
345 *based healthcare with a patient-centred approach.*

346 *2. Population-based and clinically-oriented HRA must be considered complementary and highly synergistic.*
347 However, ethical and regulatory aspects for secondary use of health data must be appropriately assessed
348 and locally implemented.

349 *3. Transferability of AMG across sites with diverse source data models is feasible, provided that*
350 *the key input variables are available, the source population is well-characterized, and adequate data*
351 *management with quality assurance over time is in place.*

352 *4. The current analysis identified the relevant steps to be considered for a generic protocol aiming*
353 *at the implementation of HRA at a regional level.*

354 5. Short-term elaboration of a map describing both maturity levels and needs for HRA adoption in
355 the twenty-one JADECARE sites could provide the necessary information to define a roadmap leading to
356 large-scale implementation of HRA across Europe.

357 **CONCLUSIONS**

358
359 The current study describes the evolution and the potential of the HRA strategy adopted in Catalonia
360 since 2010. It also illustrates the transferability of the AMG algorithm in two different scenarios.
361 Moreover, the case practice identified relevant barriers/facilitators modulating the adoption of HRA at
362 regional level and elaborated a set of key steps to be considered for site deployment of HRA. Last, but not
363 least, the report proposes initial steps to define a roadmap aiming at fostering large-scale implementation
364 of HRA across Europe.

365

366 **ETHICAL APPROVAL**

367

368 This research exclusively employed fully anonymized retrospective health records sourced from
369 administrative databases. Consequently, in compliance with prevailing legislation in the regions where the
370 analyses were conducted, neither informed consent nor ethical committee approval was required. All the
371 analytical procedures were undertaken under the auspices of the JADECARE project.

372

373 **ACKNOWLEDGEMENTS**

374

375

376 This research was funded by JADECARE project- HP-JA-2019 - Grant Agreement nº 951442 a European
377 Union's Health Program 2014-2020.
