28 Abstract

29 Mobile health (mHealth) methods have grown in popularity in preventative medicine due to their 30 convenience, cost, and ability to acquire actionable data. At the same time, the burden of many 31 diseases has grown due to their prevalence and high rates of morbidity and mortality. To 32 combat this burden, mHealth can be customized to improve adherence to recommended 33 regimens and decrease doctor or hospital visits for patients and their families. Heart failure (HF) 34 is a disease with an especially high burden for which mHealth can be used to promote 35 adherence to advised care plans with the goal of decreasing exacerbations and their associated 36 urgent and emergency care visits. Our study compared adherence to different mHealth 37 monitoring regimens that used activity trackers, scales, and a mobile app with gamification 38 features and a financial incentive. In a prospective analysis of 111 HF patients monitored for 39 180 days, we found that a regimen including a mobile app with a gamified financial incentive led 40 to significantly higher adherence to activity tracker (95% vs. 72.2%, p=0.0101) and weight 41 (87.5% vs. 69.4%, p=0.0016) monitoring compared to a regimen that included the monitoring 42 devices alone. Our findings indicate that mobile apps with added engagement features can be 43 useful tools to reduce temporal adherence decline and may thus increase the impact of mHealth 44 driven interventions.

45

46 Introduction

Heart failure (HF) is a severe health condition associated with high morbidity, mortality, and
health resource use (Al Olama et al., 2015). In the United States, 6.2 million adults have HF,
and roughly \$31 billion is spent annually on HF-related costs (Virani et al., 2020). Approximately
400,000 death certificates in 2018 cited HF and it is predicted that by 2030, cases will surge by
25% (Nelson, 2021; Benjamin et al. 2019; Virani et al., 2020). The relatively high prevalence of
this chronic disease and associated morbidity and mortality impose a substantial economic

burden on healthcare expenditures. An alarming cost increase is projected, with a total of up to
\$69.7 billion by 2030, a 127% growth since 2012 (Virani et al., 2020).

55

56 The primary contributor to HF spending is hospitalization, accounting for 75-80% of total costs 57 (Heidenreich et al., 2013). With approximately one million annual hospitalizations, HF is a 58 leading cause of hospital admissions in people over 65 (Mcdermott et al., 2005). Readmissions 59 among HF patients are, in particular, a significant concern. Approximately 1 in 4 patients are 60 readmitted within 30 days of discharge, and 1 in 2 patients are readmitted within six months of 61 discharge (Nelson et al., 2021). Clinical guidelines suggest that adherence to self-care 62 recommendations such as regular medication intake, weight monitoring, and physical activity is 63 vital to a favorable prognosis (Lainscak et al., 2011; Ponikowski et al., 2016; Riegel et al., 2009). 64 Nearly half of all HF readmissions are preventable with enhanced adherence to such self-care 65 behavior after discharge (Michalsen et al., 1998; Tsuyuki et al., 2001; Windham et al.). There is 66 a clear need to identify effective adherence-enhancing tools and methods to promote positive 67 HF health outcomes.

68

69 Mobile health (mHealth), using mobile interventions to support health, may be a preferable and 70 less intensive method to deliver medical care (Hale et al., 2015; Kumar et al., 2013; Steinhubl et 71 al., 2015). By including the use of mHealth technologies in the home monitoring of HF, patients 72 may be more inclined to play an active role in lifestyle modifications that are intended to improve 73 their health outcomes and prevent rehospitalization (Feldman et al., 2018). The use of mobile 74 applications can supplement these mHealth interventions by providing patients with an avenue 75 to monitor their progress and receive adherence notifications. Such apps are designed to serve 76 as a helpful reminder for patients to complete their daily self-care tasks, potentially increasing 77 the effectiveness of telemedicine interventions, including those involving mHealth technologies 78 (Jaarsma et al., 2000).

79

80 The use of mHealth has been expanding to include more diverse patient populations (Fiordelli et 81 al., 2013). Attributable to their remote nature and resulting accessibility, mHealth technologies 82 have extended into smartphone applications, imaging services, and other technological 83 functions. These developments can enhance support for patients by enabling them to complete 84 health and symptom monitoring surveys, providing education on risk factors, and allowing 85 patients to monitor and track health metrics continuously and in real time. Present-day home 86 monitoring interventions employ wireless sensors, telephone services, websites, and home 87 visits from nurses (Suh et al., 2011; Wakefield et al., 2009; Zan et al., 2015a). Several studies 88 using mHealth in HF patients have suffered from small sample size and poor patient adherece 89 to monitoring (Chaudhry et al., 2013; Gensini et al., 2017; Ong et al., 2016; Ware et al., 2019; 90 Zan et al., 2015b). For instance, one trial found that only 55.4% of patients randomized to 91 telemonitoring used the given technology-based intervention at least half of the time at month 92 one, and 51.7% at month six (Gensini et al., 2017). The reported low adherence levels and 93 inconclusive results associated with such studies are in part attributable to the high monitoring 94 burden of home interventions. In investigating strategies to overcome these barriers, the 95 combined use of gamification and financial incentives has yet to be extensively employed in 96 mHealth adherence studies (Tran et al., 2022).

97

98 This study evaluated differences in adherence levels to three distinct mHealth home monitoring 99 regimens in HF patients involving a combination of devices, a mobile app, and financial 100 incentives with the hypothesis that including a mobile app would boost adherence to study 101 devices. Device and app usage data from participants in each regimen were compared using 102 statistical analyses to identify any differences. Our results provide new insights into tailoring 103 mHealth interventions to drive adherence.

105 Study Design/Methods

106 Study Population

107 This prospective study included patients with heart failure at the University of California, Los 108 Angeles (UCLA) medical center. The study was approved by the UCLA Institutional Review 109 Board (IRB). Patients with an HF diagnosis were identified using our institution's electronic 110 health record (EHR). English-speaking adults aged 50-80 who had a diagnosis of HF and 111 owned a smartphone were eligible to participate in the study. Exclusion criteria included 112 participants who were receiving hemodialysis, had received an organ transplant or were on an 113 organ transplant waiting list, or did not have the cognitive or physical ability to participate.

114 Subject Recruitment

115 Figure 1 overviews our study population and recruitment procedures. Individuals who met the 116 eligibility criteria were contacted by email and text to gauge interest in the study. Over the 117 phone, research personnel contacted interested individuals to provide them with additional 118 information and conducted the verbal consent process with those interested in participating. To 119 ensure an interested individual was capable of using their smartphone, they first participated in 120 a daily survey delivered via text messages for one week. The survey consisted of three 121 questions: 1) how much did symptoms of heart failure limit your life yesterday? 2) were you able 122 to take your medication as prescribed yesterday? and 3) did you follow your recommended diet 123 yesterday? Participants who completed at least five of the seven surveys were invited to 124 participate in the full study for 180 days.

125 Study Groups

To investigate the impact of different mHealth regimens on adherence, three groups used various combinations of an activity tracker, a scale, a mobile app, and a financial incentive. The groups are defined as follows: devices only (Group D), devices and mobile app (Group D+A),

129 and devices and mobile app with a financial incentive (Group D+A+F). Group D received only 130 the devices (i.e., the activity tracker and scale). Group D+A received the devices as well as a 131 smartphone application developed by the study team. Group D+A+F received the devices, the 132 study smartphone application, and a financial incentive based on the participant's adherence, 133 which maxed out at \$150 and was paid at the completion of the monitoring period. Over the 134 phone, all participants were taught how to use the devices, and those in Groups D+A and 135 D+A+F were also taught how to access the smartphone application and navigate all features 136 within the application. Groups were also measured using standard surveys (described below).

137 Study Devices and Mobile App

138 <u>Fitbit Charge 4 (FC4) and Fitbit Charge 5 (FC5)</u>

139 The Fitbit Charge 4 (FC4) and Fitbit Charge 5 (FC5) were used in all groups to provide daily 140 feedback on a variety of parameters, such as physical activity. The FC4 (Fitbit Inc.) is a 141 commercially available wrist worn device with a 3-axial accelerometer, an altimeter, and an 142 optical heart rate tracker. Similarly, the FC5 (Fitbit Inc.) consists of a 3-axial accelerometer, 143 vibration motor, multipurpose electrical sensors, and an optical heart-rate tracker. Using these 144 components, the FC4 and FC5 track, record, and deliver real-time information on step count, 145 heart rate, sleep, and active minutes. Patients were directed to wear the Fitbit device on their 146 wrists at all times, except when charging the device. Patients were also instructed on how to 147 use the Fitbit smartphone application. The device's battery life lasts between three and five 148 days, with a charging time of approximately one hour.

149 BodyTrace Scale

Participants were provided with a BodyTrace scale (BodyTrace Inc., New York, New York) for daily weighing. The BodyTrace scale includes a cellular modem with a factory-installed SIM card. The scale arrives ready for use with four AA batteries and requires no user configuration.

Weight data is uploaded to a cloud-based database via the cellular modem. From this database,researchers can directly download the data.

155 myHeartCare Mobile Application

156 For this study, the research team developed *myHeartCare*, a cross-platform (iOS or Android) 157 mobile app capable of linking to the Fitbit tracker and BodyTrace scale. Groups D+A and 158 D+A+F, the mobile app users, downloaded this app and were instructed on navigating its 159 features. The app is divided into four sections: 1) adherence statistics, 2) surveys, 3) rewards, 160 and 4) social. A daily "To-Do" list on the statistics page prompts patients to sync their Fitbit to 161 their smartphone, weigh themselves, and complete a daily survey via the app, which used the 162 same three guestions as described above regarding diet, medication, and HF symptoms. At 9 163 AM each day participants received a push notification asking them to sync their Fitbit and take 164 their daily survey. On the statistics page, participants can also track their weight over time and 165 identify fluctuations by visualizing the recorded data from the BodyTrace scale as a time plot. 166 The survey page enables participants to access their daily surveys and the rewards page allows 167 them to monitor their study progress. For adhering to their daily tasks (syncing Fitbit, weight, 168 survey), participants in Group D+A were able to earn and track points. Those in Group D+A+F 169 were also able to accumulate and track points with the addition that points were tied to financial 170 earnings, which were displayed to the user and delivered via a cash gift card at the end of the 171 180-day study period. Additionally, the social page allowed users to invite friends and family to 172 view their adherence history and send encouraging messages.

173 Baseline Survey

Those who consented to participate in the study were administered a baseline survey consisting of questions relating to demographic information and two institutional review board-approved questionnaires—the Minnesota Living with Heart Failure Questionnaire (MLHFQ) (Bilbao et al.,

177 2016) and Patient-Reported Outcomes Measurement Information System (PROMIS) Global 178 Health (Cella et al., n.d.). These questionnaires were used to measure the HF patients' health-179 related quality of life through patient-reported outcomes using a 5-point Likert scale. Following 180 this survey, patients were officially consented into the study and randomized to one of the three 181 study groups.

182 Follow-Up Survey

183 After 180 days of monitoring, participants were contacted over the phone and administered a 184 follow-up survey. The survey consisted of the same two questionnaires administered in the 185 baseline survey-the MLHFQ and PROMIS Global Health. In addition to these questionnaires, 186 participants were asked to rate their experiences with the Fitbit and the BodyTrace scale. The 187 survey assessed factors of these devices, such as helpfulness, ease of incorporation into daily 188 life, and whether each device helped the participant adhere to their care plan. Participants were 189 then offered an option for an additional 180 days of Fitbit and BodyTrace scale data collection, 190 which did not require completion of the daily survey.

191

- 192 Figure 1. Enrollment flow diagram detailing the steps between recruiting patients with an initial message to eventually
- 193 surveying responses at the conclusion of their study period.

194

196 Data Collection and Analysis

197 The study team configured a server to connect to vendor APIs that were used to pull participant 198 data and update the myHeartCare app in real-time when a task had been completed for 199 subjects in the D+A and D+A+F groups. The server also received the responses to the daily 200 questionaire for the D+A and D+A+F groups. Three metrics were used to define adherence: if a 201 subject 1) synced their Fitbit, 2) checked their weight, and 3) completed the daily survey. 202 Adherence for each task is computed as the fraction of days the task was completed (e.g. Fitbit 203 synced) divided by the total number of days in the time period of analysis (e.g., 30 days). The 204 three groups were compared across the three measurements of adherence using Kruskal-Wallis 205 tests and Mann-Whitney U tests to make pairwise comparisons.

206 Results

207 111 participants completed the 180 study between July 2021 and April 2023. The demographics 208 of the participants who completed the study are shown in Table 1. Our results demonstrate that 209 participants within groups D+A and D+A+F had a higher adherence rate over time for the three 210 measured tasks compared to Group D. Moreover, there was a greater decline in Group D's 211 adherence rates as their participation in the study progressed relative to the groups which 212 utilized the mobile app. Figure 2 displays the average adherence of each group to the three 213 measured tasks for each day of participation in the study and Figure 3 shows box plots of 214 subject adherence over 30 day and 180 day periods.

215 <u>Fitbit Syncing</u>

Regarding Fitbit syncing, those in group D+A+F had an adherence rate of 97.5% after the first 30 days in the study and an adherence rate of 95% at the end of the 180-day period. Those in group D+A had an adherence rate of 100% after the first 30 days and 91.4% at the end of the study for syncing their Fitbit. Group D participants had an adherence rate of 97.2% after the first

30 days and an adherence rate of 72.2% at the end of the study for syncing their Fitbit. A significant difference in adherence (p < 0.05) was found between Group D and Group D+A+F during the first 30 (p=0.0097), 60 (p=.0028), 90 (p=.0051), 120 (p=.0081), 150 (p=0.0061), and 180 (p=0.0101) days of the study.

224 Self-Weighing

225 For self-weighing, Group D+A+F had an adherence rate of 92.5% after the first 30 days and 226 87.5% at the end of the study. Group D+A had an adherence rate of 94.3% after the first 30 227 days and ended with the same adherence rate for weighing themselves at the 180-day time 228 point. For Group D, the adherence rate was 94.4% after 30 days and 69.4% at the 180-day 229 period of the study ending. Statistical analysis revealed a significant difference between Group 230 D and Group D+A+F during the first 30 (p=0.0005), 60 (p=0.0001), 90 (p=0.0001), 120 (0.0006), 231 150 (p=0.0010), and 180 (p=0.0016) days of the study. There was a significant difference 232 between Group D+A and Group D+A+F only for the first 60 (p=0.031) days of the study. A 233 significant difference was found between Group D and Group D+A for the first 60 (p=0.0166), 90 234 (p=0.0119), 120 (p=0.0106), 150 (p=0.0138), and 180 (p=0.0201) days of the study.

235 Survey Taking

Participants in Group D did not have the option of taking the daily survey as they did not have the mobile app. Group D+A+F had an adherence rate of 95% at 30 days and 87.5% at 180 days. Group D+A had adherence rates of 88.6% after the first 30 days and 82.9% at the end of the study. Statistical analysis indicated only a significant difference between Group D+A and Group D+A+F for the first 30 (p=0.0391) and 60 (p=0.0347) days of the study.

Adherence across arms

246

Figure 2. Plots of adherence rates for the three primary tasks completed by study participants, classified by intervention group. Group D is classified with a solid pink line, Group D+A is classified with a dotted blue line, and Group D+A+F is classified with a dotted green line.

250

252

Figure 3. Box plots of device adherence and mobile app survey completion (D+A and D+A+F groups only) for the different groups at 30 and 180 days. Unit of analysis is a subject's fraction of days the task was completed divided by the time period. Two subjects did not have cellular service at their home, which prevented the weight scale from syncing and thus resulted in 0% adherence for the duration of the study.

257 Conclusions

Research investigating the value of remote monitoring in HF patients has generally found adherence to be a critical barrier to effective implementation. Another study of HF patients used a wireless transmission pod, a scale, and a blood pressure and heart rate monitor to capture

261 data remotely (Ong et al., 2016). At 180 days, the investigators found 68% adherence to 262 telephone coaching, but only 51.7% adherence to telemonitoring. A previous study conducted 263 by our team employed Fitbits in the remote monitoring of ischemic heart disease patients and 264 observed an adherence rate to daily syncing of 72% at the 90-day time point (Speier et al., 265 2018). This result is similar to Group D's adherence rate in the current study. In contrast, the 266 adherence rates at 90 days for Groups D+A and D+A+F were 82.86% and 90%, respectively. 267 Notably, the inclusion of a financial incentive (Group D+A+F) drove adherence significantly 268 higher than the baseline group with no app (Group D), and even Group D+A had significantly 269 higher adherence than Group D for weight monitoring. These findings support the use of mobile 270 apps to boost adherence to telemonitoring.

271 Despite higher adherence relative to previous work, we still observed adherence decay over 272 time. Future modifications to our study protocol could incorporate an incentive at regular time 273 intervals to sustain long-term adherence, such as device upgrades and more frequent financial 274 reward distributions rather than waiting until the end of the study. Additionally, real-time 275 responses could be solicited via the app to participants who begin falling in adherence, 276 providing new insights and possibly ways to improve engagement.

277 Finally, given that the app, tracker, and scale send data in real time, there is an opportunity for 278 scalable monitoring of populations using machine learning approaches that could search for 279 patients at risk of exacerbation. These algorithms would require larger datasets with which to 280 train, as well as targets defined from clinical review or patient follow-up (e.g., urgent care visits). 281 The inclusion of additional data points, such as demographics and co-morbidities, would likely 282 improve algorithm performance. Similarly, methods for tracking symptoms, diet, and medication 283 adherence more quantitatively and precisely would be important indicators for adverse future 284 events.
