- Cardiac rhythm monitoring

Abstract

Background

Prolonged cardiac monitoring (PCM) increases atrial fibrillation detection after stroke (AFDAS) but access is limited. We aimed to assess the utility of midregional pro-atrial natriuretic peptide (MR-proANP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) to identify people who are unlikely to have AFDAS and improve healthcare resource allocation for PCM..

Methods

We analysed people from the BIOSIGNAL (Biomarker Signature of Stroke Aetiology) study with ischaemic stroke, no known AF and ≥ 3 days cardiac monitoring. External validation was in the PRECISE (Preventing Recurrent Cardioembolic Stroke: Right Approach, Right Patient) study of 28-days cardiac monitoring after stroke.

The main outcome is no AFDAS. We assessed the discriminatory value of MR-proANP and NT-proBNP combined with clinical variables to identify people with no AFDAS. We determined the net reduction in people who would undergo PCM using the models with 15% AFDAS threshold probability.

Results

We included 621 people from BIOSIGNAL. The clinical model included age, National Institutes of Health Stroke Scale score, lipid-lowering therapy, creatinine and smoking status. The AUROC was 0.68 (95% CI 0.62-0.74) with clinical variables, which improved with \log_{10} MR-proANP (0.72, 0.66-0.78; $p=0.001$) or \log_{10} NT-proBNP (0.71, 0.65-0.77; $p=0.009$). Performance was similar for \log_{10} MR-proANP versus \log_{10} NT-proBNP ($p=0.28$).

In 239 people from PRECISE, the AUROC for clinical variables was 0.68 (0.59-0.76), which improved with \log_{10} NT-proBNP (0.73, 0.65-0.82; $p<0.001$) or \log_{10} MR-proANP (0.79, 0.72-0.86; $p<0.001$). Performance was better with \log_{10} MR-proANP versus \log_{10} NT-proBNP ($p=0.03$).

The models could reduce the number who would undergo PCM by 30% (clinical+ \log_{10} MR-proANP), 27% (clinical+ \log_{10} NT-proBNP) or 20% (clinical).

Conclusions

MR-proANP and NT-proBNP help classify people who are unlikely to have AFDAS and could reduce the number who need PCM by 30%.

Introduction

Atrial fibrillation (AF) accounts for 25% of ischaemic strokes.¹ One third of strokes are recurrent and anticoagulant drugs reduce the risk of recurrent strokes in people with AF.^{2,3} People are screened for AF detection after stroke (AFDAS) or transient ischaemic attack (TIA) with a cardiac monitor.

Typically, this has two stages: 1) an initial period of cardiac monitoring in all people after stroke; and 2) longer-term monitoring in people with unknown stroke aetiology. For the first stage, standard practice is an electrocardiogram (ECG) and a 24-72 hour Holter monitor that detects AF in ~4% of people.^{4,5}

Prolonged cardiac monitoring (PCM) identifies more cases of AFDAS.⁶⁻⁹ An external loop recorder for 30 days detects AF in 16% of people with ischaemic stroke of unknown aetiology.⁶ An implantable loop recorder (ILR) for one year can identify AF in up to 24% of such people.⁷

National/international guidelines recommend PCM to search for AFDAS, especially in people with ischaemic stroke or TIA of unknown aetiology.^{10,11} However, PCM is costly and is not widely available.¹² Further, while the yield of AFDAS is higher with PCM, most people tested do not have AF.^{6,7}

This could be addressed by better patient selection. A solution could be to identify people who are unlikely to have AFDAS and who do not need PCM. Prognostic scores exist for AFDAS, although these focus on people with embolic stroke of undetermined source (ESUS) who have undergone a period of monitoring or identifying people who are most likely to have AFDAS.¹³⁻¹⁷ An alternative approach is to identify people who are unlikely to have AFDAS and “rule out” rather than “rule in”.¹⁸ This would allow PCM to be focused on people who are more likely to have AFDAS and benefit from anticoagulation to prevent second AF-related strokes, while minimising potentially unnecessary tests for people who are unlikely to have AFDAS.

The natriuretic peptides midregional pro-atrial natriuretic peptide (MR-proANP) and N-terminal pro-B-type natriuretic peptide (NT-proBNP) could help stratify probability of AFDAS.¹⁹⁻²¹

Study aim

We aimed to assess the utility of MR-proANP and NT-proBNP to identify people who are unlikely to have AFDAS and improve healthcare resource allocation for PCM.

Methods

Study Design and Patient Population

We analysed people in the Biomarker Signature of Stroke Aetiology Study (BIOSIGNAL) study (NCT02274727) who were not known to have AF and who had ≥ 3 days cardiac monitoring (Supplemental Figure 1). The BIOSIGNAL study was a multi-centre, prospective cohort study that evaluated blood biomarkers associated with underlying stroke aetiology in people after ischaemic stroke.²⁰ People with ischaemic stroke were recruited from nine European stroke centres between October 2014 and October 2017.

Study Assessments and Intervention

Brain imaging, assessment of demographic variables and biochemical profile was performed on admission.

Biomarker measurement

Blood samples were collected within 24 hours of symptom onset and separated by centrifugation at 3,000g and 4°C for 20 minutes. Plasma samples were aliquoted and frozen at -80°C. MR-proANP concentrations (pmol/L) were measured using automated B.R.A.H.M.S MR-proANP immunoassay technology on a KRYPTOR instrument (B.R.A.H.M.S GmbH).²² Plasma was analysed for NT-proBNP concentrations (ng/l) using a Cobas 8000 analyser (Roche Diagnostics, Basel, Switzerland).

Cardiac rhythm monitoring

Participants had an ECG and 24 hours cardiac monitoring on admission. People with no AFDAS in the first 24 hours received further monitoring according to standard operating procedures of enrolling centres, ideally for ≥ 48 hours.⁴ In people who still did not have evidence of AFDAS, further monitoring was recommended, preferably with a 7-day ECG monitor or implantable cardiac device.

Follow-up was at 3 months and 12 months during an outpatient visit or telephone interview with a stroke physician.

Outcome measures

The main outcome is no AFDAS. AF was defined as ≥ 30 seconds of AF/atrial flutter, based on international guidelines that define clinical AF as an episode ≥ 30 seconds⁴ and is recommended as an indication for anticoagulation.²³ Central adjudication of outcomes was conducted by certified vascular neurologists and trained neurovascular fellows. In cases of disagreement, consensus was reached after discussion. To minimize bias, all outcome evaluators were blinded to biomarker levels.

Statistical analyses

Demographics

Discrete variables are expressed as counts (%) and continuous variables as median (IQR). Baseline demographics and risk factors were compared using t-tests or a non-parametric equivalent.

Logarithmic transformation (\log_{10}) was used to normalize skewed distributions.

Analyses

Univariable and multivariable logistic regression analyses were performed to evaluate associations with demographic variables and no AFDAS. Area under receiver-operating-characteristic (AUROC) curves were constructed incorporating clinical variables associated with AFDAS in univariable analysis (age, NIHSS score, creatinine, smoking and lipid-lowering medication) and \log_{10} MR-proANP or \log_{10} NT-proBNP using the pROC package and 95% confidence intervals were derived using bootstrap sampling.²⁴ We compared AUROCs for models with clinical variables versus clinical variables and \log_{10} MR-proANP or \log_{10} NT-proBNP using the Likelihood-Ratio Test for nested models. We compared AUROCs for models with clinical variables and \log_{10} MR-proANP versus \log_{10} NT-proBNP using De Long's test and continuous Net Reclassification Index (NRI).²⁵ All statistical analyses were performed using R version 4.3.

Sensitivity Analyses

Sensitivity analyses were conducted in subgroups, including: people older than the median age; female gender; NIHSS score > median; and cardiac disease, defined as prior myocardial infarction (MI) or heart failure. Sensitivity analyses were also conducted in people from the BIOSIGNAL study with i) any duration of cardiac monitoring; and ii) <3 days cardiac monitoring.

External Validation

External validation of the models with clinical variables $\pm \log_{10}$ MR-proANP or \log_{10} NT-proBNP was performed in people recruited to the ongoing Preventing Recurrent Cardioembolic Stroke: Right Approach, Right Patient (PRECISE) study.²⁶ The PRECISE study is a prospective cohort study of 28 days cardiac monitoring in people with ischaemic stroke or TIA who are not known to have AF. Participants are recruited from two Scottish stroke centres since 2021. Venous blood is collected within 5 days of hospital admission and separated by centrifugation prior to storage at -80°C. MR-proANP concentrations are measured using the B.R.A.H.M.S KRYPTOR instrument (B.R.A.H.M.S GmbH) and NT-proBNP concentrations are measured using a Cobas e411 analyser (Roche Diagnostics, Basel, Switzerland).

Participants receive 28 days cardiac monitoring with a Novacor R-test or ECG patch. The Novacor R-test has been used for all participants included in the current analysis. The primary outcome is AF ≥ 30 seconds and all AF cases are verified by two Stroke Physicians and two Cardiologists.

Decision Curve Analysis

We performed a decision curve analysis combining data from the BIOSIGNAL and PRECISE cohorts. We assessed the utility of the models to identify people who are unlikely to have AFDAS and reduce the number of people who would undergo PCM.^{27,28} We determined the net reduction in people who would undergo PCM with an AFDAS threshold probability of 15%, which was selected based on AF detection rates in the EMBRACE study⁶ and a meta-analysis of studies evaluating PCM after ischaemic stroke or TIA.⁸

Ethics and regulatory approval

The BIOSIGNAL study was approved by the local Ethics Committees of participating centres (main centre: Cantonal Ethics Commission of Zurich, BASEC-Nr. PB_2016-00672) and conducted according to the Declaration of Helsinki. All participants, or their welfare guardians, provided written informed consent. The PRECISE study is approved by the West of Scotland Research Ethics Committee 3 and all participants provide written, informed consent.

Results

Baseline characteristics

We included 621 people from the BIOSIGNAL study: 243 (39.1%) were female, the median (IQR) age was 69 (57-78) years and 77 people (12%) were found to have AFDAS (Table 1). The median (IQR) duration of ECG monitoring was 9 (7-11) days and median (IQR) NIHSS score was 4 (2-8). MR-proANP concentrations were available for 603 participants (97.1%) and NT-proBNP levels were available for 616 participants (99.2%).

People with no AFDAS were younger (median (IQR) age 68 (57-77) versus 75 (69-81) years, $p<0.001$) and had lower MR-proANP (99.3 (68.9-157.6) versus 173.4 (109.9-232.9) pmol/L, $p<0.001$), NT-proBNP (185.0 (75.5-464.0) versus 463.0 (190.0-1259.0) ng/l, $p<0.001$) and creatinine (80 (68-95) versus 83 (77-95) $\mu\text{mol/L}$, $p=0.03$) (Table 1). People with no AFDAS were more likely to have a history of smoking (27.6% versus 16.9%, $p=0.045$) and were less likely to be prescribed lipid lowering medication at baseline (26.1% versus 39.0%, $p=0.02$).

Univariable analysis

Variables associated with no AFDAS in univariable analysis were lower \log_{10} MR-proANP (OR 20.00, 95% CI 7.14-50.00, $p<0.001$), lower \log_{10} NT-proBNP (OR 2.78, 95% CI 1.89-4.17, $p<0.001$), younger age (OR 1.05, 95% CI 1.03-1.08, $p<0.001$), lower NIHSS score (OR 1.04, 95% CI 1.00-1.09, $p=0.03$), no lipid-lowering therapy (OR 1.82, 95% CI 1.10-2.94, $p=0.02$), lower creatinine (OR 1.01, 95% CI 1.00-1.02, $p=0.02$) and smoking history (OR 1.88, 95% CI 1.01-3.52, $p=0.048$) (Table 2).

Multivariable analysis

In multivariable analysis with \log_{10} MR-proANP and clinical variables associated with no AFDAS in univariable analysis, the only variable that remained associated with no AFDAS was lower \log_{10} MR-proANP (OR 8.33, 95% CI 2.50-25.00, $p<0.01$) (Table 3).

In multivariable analysis with \log_{10} NT-proBNP and clinical variables associated with no AFDAS in univariable analysis, the only variables that remained associated with no AFDAS were lower \log_{10} NT-proBNP (OR 1.85, 95% CI 1.15-2.94, $p=0.01$) and younger age (OR 1.03, 95% CI 1.01-1.06, $p=0.01$) (Table 4).

AUROC analyses

The model for predicting no AFDAS with clinical variables demonstrated AUROC 0.68 (95% CI 0.62-0.74; Table 5). Performance improved when \log_{10} MR-proANP or \log_{10} NT-proBNP was added: 0.72 (95% CI 0.66-0.78) for \log_{10} MR-proANP ($p=0.001$); and 0.71 (95% CI 0.65-0.77) for \log_{10} NT-proBNP ($p=0.009$). MR-proANP and NT-proBNP performed similarly in direct comparison of models with \log_{10} MR-proANP versus \log_{10} NT-proBNP ($p=0.28$).

Among people without AFDAS, by measuring MR-proANP a net of 55% were correctly moved towards lower probability of AFDAS, while 45% were falsely moved towards higher probability of AFDAS. The corresponding NRI was 0.30 (95% CI 0.07-0.54). Similar findings were observed for measuring NT-proBNP: a net of 55% were correctly moved towards lower probability of AFDAS, while 45% were falsely moved towards higher probability of AFDAS and the corresponding NRI was 0.39 (95% CI 0.15-0.62).

The Impact of Baseline Demographics and Cardiac Monitoring Duration on Prediction

Performance

There was no significant difference in model performance across age, gender, NIHSS score or prior cardiac disease (Supplemental Table 1). AUROCs were numerically higher in people with no prior cardiac disease for models with both natriuretic peptides. Performance of the model with clinical variables was similar in people with any duration or <3 days cardiac monitoring. AUROCs were

greater for the models with \log_{10} MR-proANP or \log_{10} NT-proBNP among people with any duration or <3 days monitoring, compared to people with ≥ 3 days monitoring (Supplemental Table 2).

External validation

External validation was performed in 239 people recruited to the PRECISE study: 94 (39.3%) were female, the median (IQR) age was 66 (59-75) years and the median (IQR) NIHSS score was 1 (0-3). The median (IQR) duration of cardiac monitoring was 28 (14-30) days and 41 people (17.2%) had AFDAS. MR-proANP and NT-proBNP concentrations were available for all 239 participants.

Compared to the BIOSIGNAL cohort, people in the PRECISE cohort were younger (median (IQR) age 66 (59-75) versus 69 (58-78) years, $p=0.04$) and had lower MR-proANP (53.7 (34.6-82.9) versus 106.7 (71.8-174.1) pmol/L, $p<0.001$) and NT-proBNP (97.5 (42.7-206.8) versus 209.0 (81.0-530.5) ng/L, $p<0.001$).

When applied to the PRECISE cohort, the AUROC was higher for the model with \log_{10} MR-proANP and similar for models with clinical variables or \log_{10} NT-proBNP (Table 5). The AUROC was 0.68 (95% CI 0.59-0.76) for clinical variables and improved with \log_{10} MR-proANP (0.79 (0.72-0.86), $p<0.001$) or \log_{10} NT-proBNP (0.73 (0.65-0.82), $p<0.001$). In the PRECISE cohort, the model with clinical variables and \log_{10} MR-proANP performed better than \log_{10} NT-proBNP ($p=0.03$).

Among people without AFDAS, by measuring MR-proANP a net of 68% were correctly moved towards lower probability of AFDAS, while 32% were falsely moved towards higher probability of AFDAS. The corresponding NRI was 0.87 (95% CI 0.57-1.16). Similar findings were observed for NT-proBNP: a net of 67% were correctly moved towards lower probability of AFDAS, while 33% were falsely moved towards higher probability of AFDAS and the corresponding NRI was 0.51 (95% CI 0.19-0.84).

Clinical Utility to Reduce the Number of People who Need Prolonged Cardiac Monitoring

Applying an AFDAS threshold probability of 15%, the estimated net reduction in people who would undergo PCM is 30% for the model with \log_{10} MR-proANP, 27% for the model with \log_{10} NT-proBNP, and 20% for the model with clinical variables alone (Figure 1, Supplemental Table 3).

Discussion

Our findings, with external validation, demonstrate that MR-proANP and NT-proBNP can help identify people who are unlikely to have AFDAS and reduce the number of people who would undergo PCM by approximately 30%. Indeed, both natriuretic peptides improve performance compared to clinical variables alone. Measuring MR-proANP or NT-proBNP to guide patient selection could help focus PCM on people who are more likely to have AFDAS and benefit, while minimising testing for people who are unlikely to have AFDAS. In healthcare systems where PCM resources are limited, it is likely that such an approach would increase the proportion of people who are found to have AFDAS and who would receive anticoagulation to prevent recurrent strokes.

Our analysis is unique as we 1) focus on identifying people who are unlikely to have AFDAS (“rule out”); 2) evaluate the role of natriuretic peptide blood biomarkers; 3) include unselected people after stroke; and 4) externally validate our findings. Previous scores to stratify probability of AFDAS focus on people with ESUS who have already undergone a period of cardiac monitoring, identifying higher risk people (“rule in”) and do not include blood biomarkers.^{16-18,29}

Our findings support that MR-proANP and NT-proBNP have strong potential to identify people who are unlikely to have AFDAS. Indeed, MR-proANP improved performance compared to clinical variables, and the model with MR-proANP had numerically greater AUROC and odds ratio than models with NT-proBNP or clinical variables alone. In multivariable analysis with MR-proANP, lower MR-proANP was the only variable associated with no AFDAS. In contrast, younger age and lower NT-proBNP were associated with no AFDAS in multivariable analysis with NT-proBNP.

The model with NT-proBNP was superior to clinical variables and NT-proBNP may also help identify people who are unlikely to have AFDAS. Previous studies support that NT-proBNP may help stratify probability of AFDAS. Indeed, sub-analysis of the Find-AF_{RANDOMISED} Trial demonstrates that a BNP threshold of 100 ng/L to select people for prolonged (3× 10-day) Holter ECG monitoring after stroke can reduce the number needed to screen from 18 to 3.²¹ NT-proBNP analysis is inexpensive, routinely used to screen for heart failure and may be more readily available in hospital laboratories or by using

point-of-care tests than MR-proANP.³⁰ Overall, both MR-proANP and NT-proBNP can help classify people who are unlikely to have AFDAS. The biomarker which performs best and would be most readily implemented in healthcare systems should be further evaluated.

Data from the general population support our findings.^{31,32} NT-proBNP and MR-proANP are independently associated with incident AF and improve performance of a model with clinical variables.³¹ Analysis of data from the LOOP trial demonstrates that people with elevated NT-proBNP benefit most from AF screening.³² Indeed, using an ILR to screen for AF in people aged ≥ 70 years prevented incident stroke or systemic embolism in people with NT-proBNP concentrations above the median, but not among people with lower NT-proBNP levels.³²

AUROC for models with MR-proANP or NT-proBNP were numerically higher in people without prior cardiac disease. This could be due to low prevalence of cardiac disease in the cohort. However, natriuretic peptides are elevated in people with cardiac disease which could influence performance in these subgroups. It is important to evaluate performance of MR-proANP and NT-proBNP in people with cardiac disease in future studies.

We determined the net reduction in people who would undergo PCM using a risk stratified approach to testing. The model with MR-proANP could reduce the number of people who would need PCM by 30%, compared to 27% for NT-proBNP and 20% for clinical variables alone. The estimates are based on 15% AFDAS threshold probability for PCM, which was selected using rates of AFDAS in the EMBRACE study and a meta-analysis of PCM after ischaemic stroke or TIA.^{6,8} Applying different AFDAS threshold probabilities would alter the net reduction in people who need PCM. However, models with MR-proANP or NT-proBNP would still reduce the number of people who need PCM by between 21% to 36% with AFDAS threshold probabilities of 10% to 20%, which would improve healthcare resource allocation for PCM.

Strengths and Limitations

A major strength is the prospective, multi-centre nature of the BIOSIGNAL study, which includes people with a range of stroke subtypes rather than only including people with ESUS. This increases

generalisability of our findings and is important given the STROKE-AF RCT demonstrates high rates of AFDAS in people with stroke attributed to small or large-artery disease.³³ All patients had ≥ 3 days monitoring and the median duration is 9 days, which is important for AFDAS case ascertainment.

External validation was performed in the PRECISE study, which has a median duration of 28 days cardiac monitoring. PRECISE is a contemporaneous, prospective cohort study with robust AFDAS case ascertainment, which is important for external validation. We evaluated and compared the utility of MR-proANP and NT-proBNP alongside clinical variables to identify people who are unlikely to have AFDAS, which we believe is a novel approach. Moreover, we determined the net benefit of using the models to identify people who are unlikely to have AFDAS and guide cardiac monitoring approaches.

Our work also has several limitations. While the sample size is reasonable, it may have been insufficient to detect a statistically significant difference in performance of the model with MR-proANP compared to NT-proBNP. While the median duration of monitoring in the BIOSIGNAL cohort is 9 days, we cannot exclude some misclassification from missed cases of AFDAS. Finally, we did not assess ECG, echocardiogram or cerebral imaging parameters as these were not routinely available for the cohorts. We also wished to avoid developing approaches to guide cardiac monitoring that involve additional tests such as echocardiograms which are not routinely performed for all people after stroke.^{10,34}

Conclusions

MR-proANP and NT-proBNP can help classify people who are unlikely to have AFDAS. Measuring MR-proANP or NT-proBNP could reduce the number of people who need PCM after stroke and improve healthcare resource allocation.

Acknowledgments

We acknowledge and thank all people who participated in the studies, and all members of the research teams at study sites.

Sources of Funding

The BIOSIGNAL study was supported by the Swiss National Science Foundation (grant 142422), the Swiss Heart Foundation, the USZ-Foundation and the Baasch Medicus Foundation. The kits for the measurement of MR-proANP in the BIOSIGNAL study were provided by B.R.A.H.M.S. Gmbh, which produces the assay. However, B.R.A.H.M.S. was not involved in the study design or analyses.

The PRECISE study is supported by the Heart Research UK (Scotland) Grant (RG2700/21/24), the Royal College of Physicians and Surgeons of Glasgow Ritchie Trust Research Award, the Mason Medical Research Trust and the University of Glasgow. Measurement of NT-proBNP levels was supported by funding from a Pfizer Quality Improvement Grant (67452629).

Table 2

Variables Associated with No AF Detection in Univariable Analysis

Variable	OR	95% CI	P-value
Lower log ₁₀ MR-proANP	20.00	7.14 – 50.00	<0.001
Lower log ₁₀ NT-proBNP	2.78	1.89 – 4.17	<0.001
Younger Age	1.05	1.03 – 1.08	<0.001
Lower NIHSS score	1.04	1.00 – 1.09	0.03
No Lipid Lowering Therapy	1.82	1.10 – 2.94	0.02
Lower Serum Creatinine	1.01	1.00 – 1.02	0.02
Smoking History	1.88	1.01 – 3.52	0.048

Odds ratios for MR-proANP and NT-proBNP are per unit log biomarker

Table 3. Variables Associated with No AFDAS in Multivariable Analysis with log₁₀MR-proANP

Variable	OR	95% CI	P-value
Lower log ₁₀ MR-proANP	8.33	2.50 – 25.00	<0.01
Younger Age	1.02	1.00 – 1.05	0.10
Lower NIHSS score	1.02	0.97 – 1.06	0.48
No Lipid Lowering Therapy	0.99	0.57 – 1.72	0.97
Lower Serum Creatinine	1.00	1.00 – 1.01	0.45
Smoking History	1.18	0.60 – 2.30	0.63

Odds ratios for MR-proANP and NT-proBNP are per unit log biomarker

Table 4. Variables Associated with No AFDAS in Multivariable Analysis with log₁₀NT-proBNP

Variable	OR	95% CI	P-value
Lower log ₁₀ NT-proBNP	1.85	1.15 – 2.94	0.01
Younger Age	1.03	1.01 – 1.06	0.01
Lower NIHSS score	1.03	0.99 – 1.08	0.16
No Lipid Lowering Therapy	1.10	0.65 – 1.89	0.72
Lower Serum Creatinine	1.00	1.00 – 1.01	0.37
Smoking History	1.31	0.68 – 2.53	0.43

Odds ratios for MR-proANP and NT-proBNP are per unit log biomarker

Table 5. Performance of the Models with Clinical Variables ± MR-proANP or NT-proBNP in the BIOSIGNAL and PRECISE Cohorts

Model	BIOSIGNAL Cohort				PRECISE Cohort			
	AUROC (95% CI)	p-value (vs clinical)	p-value (MR-proANP vs NT-proBNP)	NRI (95% CI) (Adding MR- proANP or NT- proBNP)	AUROC (95% CI)	p-value (vs clinical)	p-value (MR-proANP vs NT-proBNP)	NRI (95% CI) (Adding MR- proANP or NT- proBNP)
Clinical Alone	0.68 (0.62-0.74)				0.68 (0.59-0.76)			
Clinical and log₁₀MR-proANP	0.72 (0.66-0.78)	0.001		0.30 (0.07-0.54)	0.79 (0.72-0.86)	<0.001		0.87 (0.57-1.16)
Clinical and log₁₀NT- proBNP	0.71 (0.65-0.77)	0.009	0.28	0.39 (0.15-0.62)	0.73 (0.65-0.82)	<0.001	0.03	0.51 (0.19-0.84)

Supplemental Table 1. Sensitivity Analyses Comparing Model Performance Across Subgroups

Subgroup	N (%)	AUROC Clinical Variables (95% CI)	AUROC Clinical Variables + log₁₀MR- proANP (95% CI)	p-value (Clinical Variables + log₁₀MR- proANP by Subgroup)	AUROC Clinical Variables + log₁₀NT-proBNP (95% CI)	p-value (Clinical Variables + log₁₀NT-proBNP by Subgroup)	p-value (Clinical Variables + log₁₀MR-proANP vs Clinical Variables + log₁₀NT-proBNP)
Age > Median	311 (50.1)	0.57 (0.48-0.67)	0.64 (0.56-0.72)	0.40	0.62 (0.53-0.70)	0.27	0.25
Age ≤ Median	310 (49.9)	0.67 (0.54-0.80)	0.72 (0.60-0.84)		0.69 (0.55-0.83)		0.27
Female	243 (39.1)	0.67 (0.58-0.76)	0.72 (0.63-0.80)	0.86	0.70 (0.62-0.79)	1.00	0.42
Male	378 (60.9)	0.68 (0.60-0.77)	0.72 (0.63-0.80)		0.71 (0.63-0.80)		0.40
NIHSS > Median	279 (45)	0.70 (0.62-0.79)	0.74 (0.65-0.82)	0.68	0.72 (0.64-0.80)	0.59	0.34
NIHSS ≤ Median	341 (55)	0.65 (0.56-0.74)	0.70 (0.62-0.79)		0.70 (0.61-0.78)		0.63
Cardiac Disease	63 (10.2)	0.60 (0.38-0.82)	0.59 (0.39-0.80)	0.18	0.59 (0.39-0.80)	0.24	0.89
No Cardiac Disease	557 (89.8)	0.70 (0.63-0.76)	0.74 (0.68-0.81)		0.72 (0.66-0.79)		0.11

Supplemental Table 2. Performance of the Models Across Durations of Cardiac Monitoring in the BIOSIGNAL Cohort

	All Durations of Cardiac Monitoring	<3 Days of Cardiac Monitoring
Model	AUROC (95% CI)	AUROC (95% CI)
Clinical Alone	0.71 (0.68-0.74)	0.70 (0.66-0.74)
Clinical and log₁₀MR-proANP	0.80 (0.77-0.82)	0.82 (0.78-0.85)
Clinical and log₁₀NT-proBNP	0.78 (0.76-0.81)	0.80 (0.77-0.83)

Supplemental Table 3. Decision Curve Analysis for Reduction in the Number of People who Need Prolonged Cardiac Monitoring

Net Reduction in Number of People who Need Prolonged Cardiac Monitoring (%)			
AF Detection Threshold	Clinical Variables +	Clinical Variables +	Clinical Variables Alone
Probability	log₁₀MR-proANP	log₁₀NT-proBNP	
0	0	0	0
0.025	2.7%	1.9%	1.7%
0.05	7.9%	2.7%	1.0%
0.075	13.7%	10.1%	6.5%
0.1	21.8%	20.7%	18.2%
0.125	25.7%	25.6%	20.6%
0.15	29.5%	26.7%	20.4%
0.175	32.1%	31.4%	25.7%
0.2	36.1%	34.3%	31.4%

Supplemental Figure 1. Overview of selection of people from the BIOSIGNAL study cohort for analysis
