37 38	Abstract Objectives: Leptospira, the spirochaete causing leptospirosis, can be classified into >250
39	antigenically distinct serovars. Although knowledge of the animal host species and
40	geographic distribution of <i>Leptospira</i> serovars is critical to understand the human and
41	animal epidemiology of leptospirosis, currently data are fragmented. We aimed to
42	systematically review the literature on animal host species and geographic distribution of
43	Leptospira serovars to examine associations between serovars with animal host species and
44	regions, and to identify geographic regions in need of study.
45	Methods: Nine library databases were searched from inception through 9 March 2023 using
46	keywords including Leptospira, animal, and a list of serovars. We sought reports of
47	detection of Leptospira, from any animal, characterized by cross agglutinin absorption test,
48	monoclonal antibody typing, serum factor analysis, or pulsed-field gel electrophoresis to
49	identify the serovar.
50	Results: We included 409 reports, published from 1927 through 2022, yielding data on 154
51	<i>Leptospira</i> serovars. The reports included data from 66 (26.5%) of 249 countries. Detections
52	were from 144 animal host species including 135 (93.8%) from the class Mammalia, 5 (3.5%)
53	from Amphibia, 3 (2.1%) from Reptilia, and 1 (0.7%) from Arachnida. Across the animal host
54	species, Leptospira serovars that were detected in the largest number of animal species
55	included Grippotyphosa (n=39), Icterohaemorrhagiae (n=29), Pomona (n=28), Australis
56	(n=25), and Ballum (n=25). Of serovars, 76 were detected in a single animal host species. We
57	created an online database to identify animal host species for each serovar by country.
58	Conclusions: We found that many countries have few or no Leptospira serovars detected
59	from animal host species and that many serovars were detected from a single animal
60	species. Our study highlights the importance of efforts to identify animal host species of
61	leptospirosis, especially in places with a high incidence of human leptospirosis. We provide
62	an updated resource for leptospirosis researchers.
63	Key words: Leptospira; serovar; animals; systematic review; epidemiology

- 85 of the manuscript.

86 Introduction

87 Leptospirosis is a widespread zoonotic disease caused by bacteria from the genus 88 Leptospira, which can infect and cause disease in both animals and humans.(1) Leptospira 89 can be antigenically subdivided into >250 serovars that can be grouped into 30 90 serogroups.(2, 3) The antigenic classification into serovars is distinct from genomic 91 classification systems of species or sequence type with imperfect overlap.(4) 92 93 Although Leptospira detections have been described in a large range of animal host species 94 including mammals, reptiles, and amphibians, (5, 6) *Leptospira* spp. serovars (hereafter 95 shortened as serovars) are thought to vary in their degree of adaptation to animal species. 96 In some animal hosts, certain serovars may cause disease and establish chronic infection in 97 which Leptospira persist in the renal and reproductive tracts and produce prolonged genito-98 urinary shedding. Some host-adapted serovars have their reservoir in specific animal host 99 species, for instance serovar Icterohaemorrhagiae in Rattus species, and serovar Hardjo in 100 Bos taurus (cattle).(6, 7)

101

102 Human Leptospira infection occurs through either direct contact with an infected animal or 103 contact with soil or water contaminated by the urine of an infected animal.(8) *Leptospira* 104 infection is responsible for >1 million human illnesses and 59,000 human deaths annually.(9) 105 High incidence of leptospirosis is observed in tropical regions, urban slum environments, or 106 following flooding. Because *Leptospira* are rarely isolated in culture and uncommonly 107 detected using molecular methods from human samples, serology retains a critical role in 108 the diagnosis of human leptospirosis. Serology can identify infecting Leptospira to the 109 serogroup level which could aid to identify possible animal species as source of the human 110 infection. Knowledge of local serogroups also informs the serovar composition of 111 microscopic agglutination testing (MAT) antigen panels for locations.(10) 112 113 Knowledge of infecting serovar may have clinical implications as, although unconfirmed, 114 there is some evidence that different serovars cause varied disease severity.(11) 115 Understanding the animal host range and geographic distribution of serovars is essential 116 during epidemiologic investigations to identify local animal hosts of serovars infecting 117 people. Such information can subsequently inform control, potentially through diverse

applications such as livestock vaccine composition, or rodent control programmes.(12)

119 Conversely, gaps in our understanding of geographic and animal host distribution can impair

- 120 control efforts when important host species are unrecognized.
- 121

122 To the best of our knowledge, the 'Leptospiral serotype distribution lists' in 1966, (13) and the update in 1975 (14) were the last publications that systematically documented the 123 124 animal host range and geographic distribution of serovars. There has since been 125 considerable research on leptospirosis, with developments in classification, and recognition 126 of new serovars.(4) Further, the development of systematic review methods may identify 127 additional reports prior to 1975 that were not included in the historic distribution lists. 128 Although recent systematic reviews have focused on specific regions or animals, (15-17) a 129 comprehensive and updated resource documenting the animal host range of serovars is 130 lacking. Therefore, we aimed to synthesize the literature on animal host species and 131 geographic distribution of *Leptospira* serovars to (i) examine associations between serovars with animal host species and regions, (ii) identify geographic regions in need of study, and 132 133 (iii) make data available through a curated online database.

134

135 Methods

136 We undertook a systematic review to identify all reports of *Leptospira* spp. identified to the 137 serovar level detected in animal hosts. Our review followed Preferred Reporting Items for 138 Systematic Reviews and Meta-Analyses (PRISMA) guidelines.(18) Although the International 139 Prospective Register of Systematic Reviews (PROSPERO)(19) recently has allowed 140 registration of systematic reviews of animal studies, this was not available at the start of our 141 study in 2015. We searched nine databases: BIOSIS; CAB abstracts, including Aquaculture 142 Compendium, CABI Full Text, Global Health and Leisure Tourism; Ovid Medline; PubMed; 143 Proquest Agricultural Science Collection; Scopus; Web of Science; Wildlife and Ecology 144 Studies Worldwide; and Zoological Record. Key search terms included 'animal', 'Leptospira', 145 'serovar', and a list of serovars (Text S1). A clinical librarian (SG) searched each database 28-146 31 August 2015. The search was updated on 9 March 2023. Our search was not limited by 147 year, publication type, or language. In addition, we searched the Amsterdam Medical Centre 148 Leptospira library for additional articles listed for reference strain provenance.(3)

149	
150	We included papers that reported <i>Leptospira</i> infection in an animal host, detected by
151	culture or molecular testing, in which <i>Leptospira</i> was characterized to the serovar level by
152	an acceptable method. Acceptable methods for identifying serovar included cross agglutinin
153	absorption test (CAAT), monoclonal antibody typing, serum factor analysis, and pulsed-field
154	gel electrophoresis (PFGE).(20-22) We included reports where typing methods were not
155	explicitly stated but were performed at a reference laboratory and could be inferred to use
156	the acceptable methods. We included only papers in which the common or scientific name
157	of the animal was provided. We excluded papers in which animals had been experimentally
158	infected and in which the isolate was not characterized to the serovar level.
159	
160	First, a single author (MJM or NNH) reviewed all titles and abstracts for eligibility. For
161	reports that passed abstract and title review, two independent reviewers (MJM and one of
162	BC, ED, JH, KC, KS, MC, MPR, NNH, NS, SCG) reviewed the full-text. Final decision on
163	eligibility was resolved through consensus or by decision of a third reviewer (JAC).
164	
165	Data abstraction
166	Data were abstracted into the database Airtable (Airtable, San Francisco, CA, United States)
167	by MJM or NNH. We recorded: the period of sample collection; common and scientific name
168	of the infected animal; country, number, age, and health status of the infected animal; the
169	biologic sample from which Leptospira was detected; methods used for Leptospira detection
170	and serovar determination; and serovar. For detections of serovar Hardjo, we also collected
171	the subtype as Bovis, Prajitno, or not determined.
172	

Publication year was grouped into 25-year periods. Geographic region was determined to the country level as defined by the United Nations (UN) and countries were grouped according to UN region and subregion.(23) We used the Integrated Taxonomic Information System to update and correct animal host scientific names that had changed from historic publications.(24) We inferred animal scientific names to either the genus or species level from common names for livestock species (e.g., *Bos taurus* for cattle), and for animal common names that described a single genus or species. Subsequently, all animals were

180 grouped by animal order and animal class. The serogroup to which each serovar belonged

181 was determined from existing reference lists.(3, 25)

182

183 Data analysis

184 First, we described the publication year, country, and methods for serovar determination of

185 the included reports. Second, we described the number of reported serovars and the

186 number of unique animal host species with detected serovars. Third, we evaluated the

animal host species range of detected serovars. For each serovar, we aggregated the

188 number of detections by animal host identified to genus, species and order level, and

189 visualised the serovar distribution by animal hosts using heat maps.

190

191 For the geographical distribution of serovar detections, we described the number of unique

192 serovar detections by UN region and subregion. For each UN region and subregion, we

193 counted the number of reports of animal detections per serovar. In addition, we counted

194 the serovars that were detected in each UN region, and the serovars that were detected in a

195 single region. The analysis of the geographical distribution of serovars were repeated for the

196 three animal host orders with the largest number of reports.

197

Among countries with an estimated incidence of human leptospirosis >50 cases per 100,000
 people,(9) we counted the number of reports of serotyped *Leptospira* detected in animal
 host species.

201

202 We generated summary tables of abstracted data of serovar detections per animal host

203 species and geographic area, grouped by serogroup. In addition to tables, we developed an

204 online searchable database named for Dr. Leopold Kirschner, (26, 27) a prominent

205 leptospirosis researcher who worked at the University of Otago. Data analyses were

206 performed in R version 4.2.

207 **Results**

208 We identified 11,173 unique reports (Figure 1), with 1,862 (17.7%) included for full-text

209 review after title and abstract screening. We completed full-text review of 1,697 (91.1%)

210 reports, could not locate 79 (4.2%) reports, and were unable to translate 86 (4.6%) (Table

S2, Text S3). Analysis included 409 reports: thirteen (3.2%) reports were published from
1927-1950, 158 (38.6%) from 1951-1975, 160 (39.1%) from 1976-2000, and 78 (19.1%) from
2001-2022 (Figure S5). For the reported methods of serovar detection, 265 (64.8%) reports
used CAAT, 61 (14.9%) used monoclonal antibodies, 42 (10.3%) used PFGE, and 14 (3.4%)
used serum factor analysis. For 66 (16.1%) reports, serovar detection was inferred to be
performed by acceptable techniques at a reference laboratory. Multiple methods were used
in 34 (8.1%) reports (Table S6).

218

219 Serovar detections across animal host species

220 The median (IQR) number of individual animal hosts contributing serotyped isolates was 4 221 (1-13) across 366 reports with available data. Overall, the 409 reports yielded data on 144 222 different animal hosts for which genus and species were identifiable, and an additional 6 223 animal hosts for which only the animal order could be identified. Among the 144 reported 224 animal host species, 135 (93.8%) were from the class Mammalia, 5 (3.5%) from Amphibia, 3 225 (2.1%) from Reptilia, and 1 (0.7%) from Arachnida. Of the 16 identified animal host orders. 226 Rodentia (e.g., rats) were described in 186 (45.5%) reports, Artiodactyla (e.g., cattle) in 148 227 reports (36.2%), Carnivora (e.g., dog) in 85 (20.8%) reports, Didelphimorphia (e.g., opossum) 228 in 24 (5.9%) reports, and Eulipotyphla (e.g., shrew) in 19 (4.6%) reports. Other animal host 229 orders are shown in Table S7. Animal age and animal health status were not provided, in 230 293 (71.6%) and 295 (72.1%) reports, respectively (Table S8).

231

232 Among the 409 reports, the median (IQR) number of detected serovars was 1 (1-2). Overall, 233 154 different serovars were reported from 25 serogroups. Five serovars could not be 234 classified to the serogroup level. Serovars that were most frequently reported included 235 Icterohaemorrhagiae (n=63), Pomona (n=61), Hardjo (n=54), Canicola (n=51), Grippotyphosa 236 (n=48), and Ballum (n=40) (Figure 2A). Among 53 reports that detected serovar Hardjo, 11 237 included serovar Hardjo subtype Bovis, 6 included serovar Hardjo subtype Prajitno, and in 238 42 Hardjo subtype was not further determined. Across 144 animal host species with an 239 identifiable genus and species, the serovars detected in the largest number of different 240 animal species included Grippotyphosa (n=39), Icterohaemorrhagiae (n=29), Pomona 241 (n=28), Australis (n=25), and Ballum (n=25) (Figure 2B). Of serovars, 76 were detected in one 242 animal host species, and 32 serovars in two animal host species. Among animal host species,

the largest number of serovars were detected in *Bos taurus* (n=43), *Rattus rattus* (n=30), *Mus musculus* (n=23), *Sus scrofa* (n=23), *Canis lupus* (n=21), and *Rattus norvegicus* (n=20)
(Figure S8).

246

The number of detected serovars ranged from 1 through 90 across the 16 animal host
orders: 90 serovars in Rodentia, 58 in Artiodactyla, 34 in Carnivora, 31 in Didelphimorphia,
17 in Eulipotyphla, and 10 or less serovars in the other 11 animal host orders (Figure 3).
Serovar Grippotyphosa was detected in 10 animal host orders. 95 serovars were detected in
a single animal host order, and 33 serovars in two animal host orders. The median (IQR)
number of animal host orders in which the remaining 25 serovars were detected was 4 (35).

254

255 Serovar geographical distribution

256 Of 409 included reports, 28 (6.9%) were from Africa, 169 (41.3%) from the Americas, 90 257 (22.0%) from Asia, 103 (25.2%) from Europe, 23 (5.6%) from Oceania, and none from 258 Antarctica (Table 1, Figure S4). UN subregions lacking reported data were Middle Africa and 259 Micronesia. The reports included data from 66 (26.5%) of 249 countries, including 9 (15.0%) 260 of 60 countries in Africa, 17 (29.8%) of 57 countries in the Americas, 15 (30.0%) of 50 261 countries in Asia, 21 (40.4%) of 52 countries in Europe, and 4 (13.8%) of 29 countries in 262 Oceania (Table 1). The number of detected serovars varied by region: 29 serovars were 263 detected in Africa, 86 serovars in the Americas, 54 serovars in Asia, 36 serovars in Europe, 264 and 20 serovars in Oceania (Table 1). Serovars detected at least once from each of the five 265 UN regions included serovars Australis, Ballum, Grippotyphosa, Hardjo, and Pomona. Of 117 266 serovars that were detected in a single UN region, 13 (11.1%) were detected in Africa, 60 267 (51.3%) in the Americas, 27 (23.1%) in Asia, 10 (8.5%) in Europe, and 7 (5.9%) in Oceania. 268 269 Of 27 countries with an estimated annual incidence of leptospirosis >50 per 100,000

people, (9) 6 (22.2%) countries had available reports of *Leptospira* detection from an animal

host species and 21 (77.8%) had no report. Across the six countries with reports, the median

272 (IQR) number of reports was 2 (1-4) (Table S9). Of the 21 countries with no reports, five

273 (Comoros, Mauritius, Rwanda, Sao Tome and Principe, Seychelles) were in Africa, five

274 (Antigua and Barbuda, Jamaica, Saint Kitts and Nevis, Saint Lucia, Saint Vincent, and the

Grenadines) in the Americas, two (Maldives, Timor-Leste) in Asia, and nine (Fiji, Kiribati,
Federal states of Micronesia, Palau, Samoa, Solomon Islands, Tonga, Tuvalu, Vanuatu) in
Oceania.

278

279 The largest number of reports were on animal host order Rodentia, Artiodactyla, and 280 Carnivora. Of 90 serovars detected in hosts of the order Rodentia (Figure 4), serovars 281 detected at least once from each UN region were serovars Australis, Ballum, and 282 Grippotyphosa. Of 58 serovars detected in hosts of order Artiodactyla, serovars detected at 283 least once from each UN region included serovars Grippotyphosa, Hardjo, and Pomona. The 284 distribution of serovar Hardjo subtypes among Artiodactyla order hosts was subtype Bovis 285 in four regions (Africa, the Americas, Europe, and Oceania), subtype Prajitno in two regions 286 (Europe, the Americas), and subtype not determined in all five regions. Of 34 serovars 287 detected in hosts of order Carnivora, no serovars were detected in all five UN regions. 288 289 Serogroups from which all serovars were isolated in animal hosts from a single UN 290 subregion included serogroups Cynopteri and Iquitos reported only from South America 291 (Peru), and serogroup Hurstbridge reported only from Australia and New Zealand

- 292 (Australia).
- 293

294 Online database

- The animal host species and country of origin for serovars are shown in Table S10 and the curated online database can be found at
- 297 <u>https://www.otago.ac.nz/internationalhealth/research/leptospirosis/</u> [this is a pilot version,
- the final version will be available upon publication]. The database is searchable by serovar,
- serogroup, country, animal scientific name, and animal common name.

300 Discussion

- 301 With this systematic review, we synthesize the literature on *Leptospira* serovar isolations
- 302 and detections in animal host species and make these data available through a curated
- 303 online database. This updated *Leptospira* serovar database on serovar animal host range
- 304 could aid investigations of and response to leptospirosis outbreaks,(10) and inform
- 305 leptospirosis control programs by suggesting which animal host species might be the source

306 of infection. For example, in a human population in rural Rwanda, Ntabanganhiman et al. 307 found a high prevalence of *Leptspira* in human samples. (28) Of these, MAT results 308 suggested that mosts infections were caused by serogroup *Icterohaemorrhagiae*, but the 309 potential animal source of infection was unclear and there are not typed Leptospira isolates 310 from Rwanda. Our systematic review found that serovars from the Icterohaemorrhagiae 311 serogroup have been isolated from pouched rats and cattle in countries neigbouring 312 Rwanda, providing hypotheses regarding possible host animal sources. (29-32) In addition, 313 our database may facilitate detection of cases of human leptospirosis by informing serovar 314 composition of MAT antigen panels.

315

Our systematic review used a rigorous process and included published reports that were indexed in the searched databases and used acceptable methods for serovar determination. We identified serovar detections in animal hosts in 66 countries. Previous reviews in 1966 and the update in 1975 reported detections in animals in 71 countries respectively, but were based on unpublished data and personal communications.(13, 14) Since country borders and country names have changed over the period in which included reports were published, a comparison of number of countries was not possible.

323

324 Overall, Leptospira detections were reported from a small proportion of all known animal 325 species. Serotyped Leptospira detections were predominantly from mammals, but among 326 mammals, we found *Leptospira* detections from <2% of the approximately 6,000 currently 327 described mammalian species. (24) There were also reports of detection from reptiles and 328 amphibians, and one report of detection from arachnids. We did not identify reports of 329 detection of adequately typed Leptospira from birds or fish.(33, 34) Some Leptospira 330 serovars were detected from a limited number of animal species whereas others were 331 detected from a diversity of animal species. For instance, serovar Grippotyphosa showed 332 the largest host range with detections across 39 different animal host species from 10 333 animal host orders. On the other hand, some frequently reported serovars were detected in 334 one or two animal species. For example, serovar Hardjo was mainly detected in cattle, and 335 serovar Canicola in dogs. More than 100 serovars were detected in only one or two animal 336 species. It is possible that human Leptospira infection with a serovar that has a narrow host 337 range implicates the likely source of infection. However, variation in the number of serovar

detections by animal species was potentially influenced by differences in host susceptibility,
and lack of research on many animal species. Our results should be interpreted with caution
and the lack of identification of a serovar from any particular animal species should not be
interpreted as an inability to infect that species.

342

We have confirmed that *Leptospira* are geographically widespread, with typed isolates 343 344 detected from animal hosts in every continent except Antarctica. Despite this, there are 345 many countries with few or no serovar detections, including countries in Africa and Oceania 346 thought to have a high incidence of human leptospirosis.(9) It is likely that the absence of 347 information reflects a lack of research rather than an absence of animal *Leptospira* infection 348 in those countries. We note that many countries with a high incidence of human 349 leptospirosis that lacked data on Leptospira detection from animal hosts are island 350 nations.(9, 15) Importantly, each island might have local variation in factors influencing 351 leptospirosis epidemiology including biodiversity, ecosystem, and human-animal 352 interactions.

353

354 There were several serovars and serogroups reported from a limited geographic range,

while others had a broader geographic distribution. An example of a serovar with a limited geographic range is serovar Saxkoebing, detected exclusively in Europe. However, as it was detected in mice, voles and dogs, which are widespread in other regions, it is possible that the geographic range of serovar Saxkoebing is wider than what is currently reported. On the other hand, serovars Australis, Ballum, Grippotyphosa, Hardjo, and Pomona were identified in all five UN regions, suggesting wider geographic distribution.

361

Of the >250 serovars of *Leptospira* recorded, (20) we identified reports of detection of 154
 serovars from animal hosts. Data on detection from an animal species are lacking for many
 serovars. For many others, we found just a single report of detection in an animal species.
 Potential explanations include highly localized epidemiology of particular serovars,
 occasional exposure of animals to serovars for which the environment acts as a reservoir,

367 variation in host range for some serovars, or insufficient research and reporting of animal

- 368 *Leptospira* infection in many areas.
- 369

370 Our study has some limitations. We cannot establish if the absence of a serovar from a 371 location or animal is a result of a report being missed by our systematic review process; or 372 not being sought, detected, or reported by researchers; or not being present. *Leptospira* 373 culture is insensitive and shedding of bacteria by host animals can be intermittent.(35, 36) 374 Loss of provenance of isolates is also a limitation of our study, as detailed typing of isolates 375 by reference laboratories may be performed without citing the origin of the isolate. It is also 376 likely that there has been misclassification of reported isolates, particularly as serovar 377 classification has undergone several major changes, with the alteration in the definition of 378 serovar, and renaming of serovars. (4, 20, 37) Early serotype determinations were not standardized and the reference standard for most of the 20th century. CAAT, is a complex 379 380 test to perform. As evidence of these difficulties, we identified published reports in which 381 authors identified errors in their own earlier classification of isolates. (38, 39) Lastly, we did 382 not perform a bias assessment of the included reports as we focused solely on serovar 383 detections of animal hosts and only selected reports that used appropriate methods of 384 serovar detections.

385

386 Conclusion

387 In conclusion, we have performed a systematic review on Leptospira serovar isolations and 388 detections from animal host species worldwide using contemporary systematic review 389 methods and made them available in a curated publicly accessible database. In so doing, we 390 have identified that there are few published data on *Leptospira* serovars from animal host 391 species from multiple countries considered to have a high incidence of human leptospirosis, 392 especially those in Africa and Oceania. We anticipate that our updated review and database 393 will provide a useful resource for public health practitioners and leptospirosis researchers, 394 and inform efforts to control and prevent leptospirosis.

395

396 Acknowledgments

397 The authors would like to thank University of Otago librarians, particularly Jacinda Boivin,

- Jessie Neilson, Susan Pennock, Dierdre O'Neill, Jan Wyllie and Tanya Low; as well as
- 399 colleagues at libraries around the world who helped collect the full-text articles for review.
- 400 The authors would also like to thank Gary Niemi, Geoffrey Hughes, Louis Prior, and Kevin

- 401 Maeer, Applications Development Team, Information Systems Group, ITS, University of
- 402 Otago, for development of the online database.

403

- 404 Disclaimer
- 405 The findings and conclusions in this report are those of the authors and do not necessarily
- 406 represent the official position of the US Centers for Disease Control and Prevention. Use of
- 407 trade names and commercial sources is for identification only and does not imply
- 408 endorsement by the US Department of Health and Human Services or the Centers for
- 409 Disease Control and Prevention.

410
