13th October 2023

Abstract

Data Envelopment Analysis (DEA) has been employed as a performance evaluation tool in the evaluation of efficiency and productivity in numerous fields. This includes hospitals in particular as well as the broad healthcare industry. This review examines 89 papers that discuss the use of DEA in hospitals, paying particular attention to approaches for choosing inputs and outputs as well as the most recent developments in DEA studies. English articles with empirical data from year 2014-2022 (Web of Science, Scopus, PubMed, ScienceDirect, Springer Link, and Google Scholar) were extracted based on PRISMA methodology. DEA Model parameters were specified based on previous studies and approaches were identified narratively. The approaches can be grouped into four: (1) Literature review, (2) Data availability, (3) Systematic method and (4) Expert judgement. The approaches were applied as

30 one strategy either by itself or in combination with others. This review's emphasis on approaches used
31 in hospital may constrain its conclusions. There might be another strategy or method used to select the
32 input and output for a DEA study in a different area or strategies based on different viewpoints. The
33 trend for DEA application were quite similar to previous studies. There is no evidence that one model
34 fits all DEA model parameters better than another. Based on the reviewed literature, we offer some
35 recommendations and methodological principles for DEA studies.

36

37 Keywords: Data Envelopment Analysis, Hospital, Efficiency, Inputs, Output.

38

39

40 **Introduction**

41

42 Efficiency is a term that does not need to be introduced in the world of economics. Following the
43 seminal works of Farrell in 1957, which showed the measurement of efficiency as one that accounts for
44 all inputs and outputs while avoiding index number issues and demonstrating how it may be calculated
45 in practice. Indeed, the studies of efficiency gained much interest not only from statisticians and
46 economists but a wider range audience [1]. These include those in the healthcare and medicine areas.
47 There is no consensus on the best method to measure efficiency. Measurement techniques such as Data
48 Envelopment Analysis (DEA), Stochastic Frontier Analysis (SFA), Pabon Lasso, and Ratio Analysis
49 are among the various methodologies used for efficiency studies in health facilities [2–4]. In the Global
50 Programme on Evidence for Health Policy Discussion Paper Series by World Health Organization
51 (WHO) unveiled their own method for evaluating the effectiveness of healthcare systems. They
52 explicitly specified the broad set of goals of the health system, including responsiveness (both level and
53 distribution), fair finance, and health inequality, in addition to the more conventional goal of population
54 health, in contrast to past work in this field [5]. While in another report, the WHO measures the health

55 system's performance by introducing a measure of national health systems' success in attempting to
56 meet three broad goals: good health, responsiveness to the population's expectations, and fairness of
57 financial contribution [6]. Even with that, there is controversy and critique on the method used while
58 there is an agreement on making those assessments correctly focus, analyse more critically, more
59 positively, and aid in a crucial conversation between health systems stakeholders [7–9]. In a more recent
60 years, DEA has been used to measure the efficiency of 180 countries based on six key dimensions of
61 healthcare systems namely clinical outcomes, health adjusted life years, access, equity, safety, and
62 resources [10].

63 Thus, the stakeholders must understand there cannot be efficiency metrics that are universally
64 applicable and appropriate for all healthcare systems. It is vital to have a thorough grasp of the
65 institutional arrangements, data, and measurements in order to choose suitable measures, resources, and
66 other parts of the health system, and a framework is designed. in keeping with the analysis. It should be
67 noted that the optimal method to apply performance measurement is not to determine the one simple
68 adjustment that can be made in a supporting role to enhance one of the health system outcomes, but to
69 employ it as a means of gauging performance more broadly among the various system components
70 [11,12].

71 Numerous indicators, ranging from measures that compare activities to measures that compare
72 expenses, are available to determine if limited resources for health are being used most effectively. The
73 use of quantitative metrics in evaluating hospital performance is primarily of interest. Additionally, a
74 wide variety of indicators were utilized to assess the quality of hospital services [13,14]. Efficiency
75 comparisons can be transparently compared using techniques based on strong economic theory. Two of
76 the most popular techniques for calculating the effectiveness of health care are data envelopment
77 analysis (DEA) and stochastic frontier analysis (SFA) [11]. Over the past 40 years since the earliest
78 study by Nunamaker in 1983, these techniques have been applied extensively in published applications
79 in healthcare settings [15–19]. Especially DEA despite the known theoretical and methodological
80 limitations had gained interest from researchers to address these limitations and development of

81 multiple methods which integrate DEA with other statistical techniques and methodologies to improve
82 efficiency evaluation [20,21].

83

84

85 **1.1 DEA as an efficiency analysis tool in hospital**

86

87 DEA is a mathematical technique for assessing the relative efficiency of homogenous decision-making
88 units (DMUs) with many inputs and numerous outputs. It was originally created within the operations
89 research and econometrics disciplines. The disadvantage of DEA is that it is non-parametric and
90 deterministic, which indicates that outliers are more noticeable. The effectiveness of a DMU is then
91 evaluated in comparison to the effectiveness of every other member of the group: The most effective
92 DMUs are those at the efficiency frontier, which have maximum outputs produced by using the same
93 level of inputs as all other DMUs [17,22]. In the DEA literature, this is a well-known CCR model
94 (Charnes, Cooper, and Rhodes) or Constant Return to Scale (CRS) assumption as the input-output
95 correlation can be examined even in the absence of congestion effects of any kind. In other words, the
96 output may increase in a precise linear relationship with the inputs [10,23]. This model and assumption
97 were further extended by Banker with the BCC model (Banker, Charnes, and Cooper) and variable
98 returns to scale (VRS) assumption which assumes that economies' scales shift as the DMU's size grows
99 [23,24].

100 Aside from the model type and return to scale assumption, DEA also considers the model orientation
101 either input-oriented or output-oriented. The assumption behind input orientation is that a DMU can
102 control more inputs than outputs. The opposite argument, however, might be made: that given their
103 ability for inputs to raise their organization's efficiency, the organizations can increase their outputs
104 [23,25]. When calculating a DMU's or an organization's efficiency using DEA, it's critical to note the
105 inputs and outputs. The selection and combination of both must be precise, thorough, pertinent, and
106 appropriate in order to accurately depict the hospital's functions and satisfy the needs of stakeholders

107 who are evaluating the hospital's efficiency [18,21]. In addition to this, advanced analysis had been
108 incorporated in DEA which includes further models of CCR and BCC, longitudinal or window analysis
109 including The Malmquist index, statistical analysis such as regression and bootstrapping method
110 [20,23,25–27].

111

112

113 **1.2 Input and output selection in hospital DEA application**

114

115 Numerous studies have been published to demonstrate the usefulness and potential of DEA in
116 evaluating hospital efficiency[28–31]. Although creating hypotheses by comparing DEA ratings across
117 several hospital studies is helpful, there are significant drawbacks.

- 118 • varying input and output metrics throughout various time frames
- 119 • the DEA score distribution is so skewed that relying on the standard measures of central
120 tendency will be inaccurate
- 121 • the study's output metrics diverge greatly from one another
- 122 • hospital production models and types that differ greatly

123 However, there have been creative and innovative studies conducted at the hospital level that may be
124 helpful to decision-makers [23,32]. The methodology of DEA has been the subject of dozens of review
125 studies on hospital application. General applications of DEA to health care performance
126 measurement[15,16,18], categorization or clustering of DEA technique [20,33], comparing DEA
127 analysis between other methods, between countries or between two periods [28,30,34,35], or new
128 knowledge and new approach on the assessment of DEA [17,21].

129 A systematic literature review (SLR) uses organized, transparent, and replicable techniques at each
130 stage of the process to completely discover and synthesize literature that is relevant to a certain subject.
131 It adheres to a protocol (detailed plan) that predetermines its main goals, ideas, and techniques.

132 Decisions and actions are meticulously recorded so that readers can follow them and assess the
133 reviewer's methodology [36]. Despite the large number of studies on the use of DEA in hospitals, efforts
134 to comprehensively examine these studies are still missing and warrant more investigation. This article
135 identifies and describes DEA research in hospitals in an effort to close the knowledge gap.

136 What is the approach to choose the optimal input and output for measuring DEA efficiency is the major
137 research topic that served as the foundation for the current article's systematic literature review? This
138 study's primary emphasis is on the approach or way of selecting the input and output adopted by
139 researchers in the application of DEA. Hospitals received special attention because they are among the
140 institutions whose efficiency is hardest to gauge because of their dynamic nature of service production
141 and variation across providers [25,37,38]. To the best of our knowledge, no research has previously
142 looked into or investigated the approach in selecting input and output with a focus on DEA hospital
143 applications. Due to this, we carried out this research. In addition, this study observed the current trend
144 in analysing hospital efficiency using DEA.

145 The remainder of this essay is structured as follows: The methodology section and the PRISMA
146 Statement (Preferred Reporting Items Systematic Reviews and Meta-Analysis) methods are described
147 in the second section. The scientific literature is methodically reviewed and synthesised in the third
148 section, and the approach used to select the input and output for DEA in hospitals are examined and
149 evaluated in the fourth section. Limitation and conclusion are outlined in the final section.

150

151

152 **Methodology**

153

154 This section discusses the process used to find articles on DEA that are relevant to gauging hospital
155 efficiency. We employed the PRISMA methodology, which consists of resources (Web of Science,
156 Scopus, PubMed, ScienceDirect, Springer Link, and Google Scholar) used to conduct the SLR,

157 eligibility and exclusion criteria, review process steps (identification, screening, eligibility), and data
158 abstraction and analysis.

159

160

161 **2.1 PRISMA**

162

163 PRISMA is a minimal set of elements for reporting in systematic literature reviews and meta-analyses
164 that are supported by evidence. PRISMA is primarily concerned with reporting reviews that assess the
165 effects of interventions, but it can also serve as a foundation for reporting SLR with goals other than
166 assessing interventions [39]. Future researchers should be provided with a comprehensive manual on
167 the SLR methodological approach. The first step in SLR is to create and validate the review procedure,
168 publication standard, and reporting standard/guidance, which are manuals of systematic plans that direct
169 researchers on what should be taken into account throughout the review [40].

170

171

172 **2.2 Journal databases**

173

174 Six databases were used to search for articles published from 2014 until 2022 and these were Web of
175 Science, Scopus, PubMed, ScienceDirect, Springer Link, and Google Scholar. There are noticeable
176 performance variations across the search engines analysed, demonstrating that there is no ideal search
177 method. Their effective usage consequently necessitates that searcher are well-trained, can assess a
178 system's strengths and shortcomings, and can decide where and how to search based on that information.
179 We chose the six databases because they may offer a carefully curated medical database with features
180 and tools that help with recall and a wide range of options to maximize precision [41,42].

181

182

183 **2.3 Identification**

184

185 The systematic review procedure included four steps. During the first stage, search terms were
186 identified. We performed a search based on prior research using the terms “efficiency*”,
187 “performance*”, “productivity*”, “benchmark*”, “hospital*”, “data envelopment analysis”, and
188 “DEA”.

189

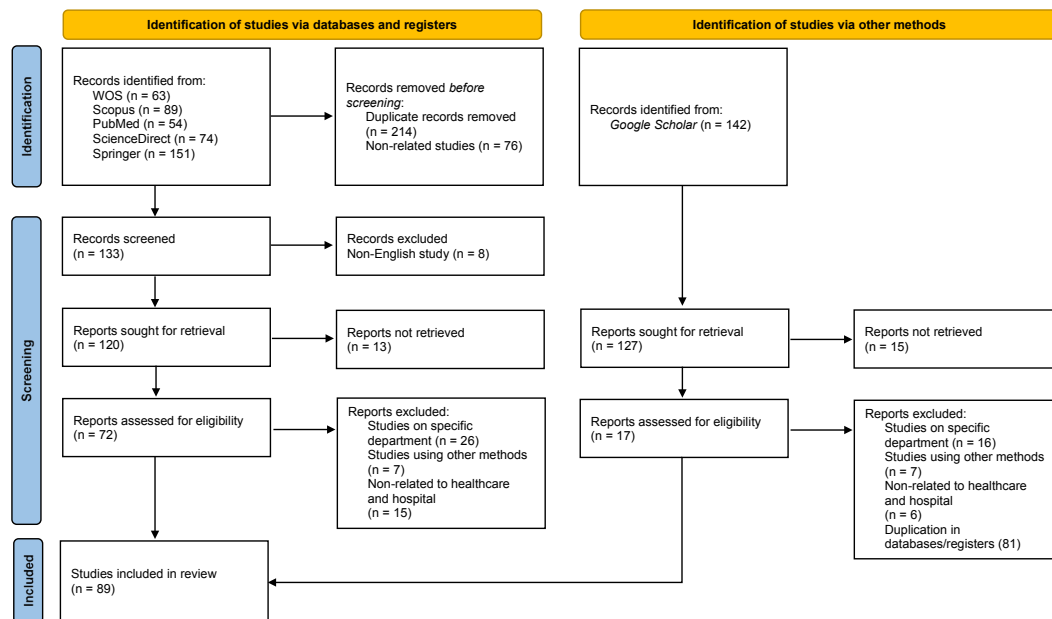

190

191 **2.4 Screening**

192

193 We established inclusion and exclusion criteria. To start, only journals with articles containing
194 empirical data are chosen, therefore review articles (SLR and SR), book series, books, chapters in
195 books, and conference proceedings are all disregarded. Second, the search attempts excluded non-
196 English publications and concentrated only on items written in English, avoiding any ambiguity or
197 difficulty in translation. Thirdly, in terms of the chronology, a period of 9 years is chosen (between
198 2014 and 2022), which is long enough to see changes in research and publications that are connected.
199 The period selected also aims as a continuation of the previous study by O’Neill et al. (1984 to 2004),
200 Cantor & Poh (1994 to 2017), and Kohl et al. (2005 to 2016). The final number of articles for the quality
201 appraisal stage were 89. A PRISMA (Fig 1) diagram provides a detailed description of the entire search
202 procedure.

203 **Fig 1. PRISMA diagram of the search process**

204

205

206 2.5 Quality appraisal

207

208 To make sure that the methodology and analysis of the chosen studies were done in a satisfactory
 209 manner, the quality appraisal stage was carried out. For this purpose, we used two quality appraisals
 210 tools that cover knowledge transfer [35,43] and economic evaluations and efficiency measurement
 211 [44,45]. The fifteen-point scale developed by Mitton et al. covered the following topics: evaluation of
 212 the literature and identifying research gaps; research question and design, validity, and reliability; data
 213 collecting; population and sampling; and analysis and reporting of results. These criteria were given a
 214 score of 0 for not being present or reported, 1 for being present but of low quality, 2 for being present
 215 and of mid-range quality, or 3 for being present and of high quality [43]. While The four dimensions
 216 covered by the Varabyova and Müller checklist were reporting, external validity, bias, and power. The
 217 quality assessment checklist's items were all given a score of 0 (no/unclear) or 1. (yes). One item was
 218 specific to research using a second-stage analysis since it addressed the potential sources of bias in the
 219 study. Studies that did not undertake a second-stage analysis received a maximum score of 13, while
 220 studies that did receive a second-stage analysis received a maximum score of 14. Only the items relevant
 221 to that study's design were used to determine the maximum score (100%) for each study [45].

222 We are not aware of any such established standards for evaluating the planning or execution of research
223 on healthcare efficiency indicators. Thus, in order to be more robust and minimize bias, we choose to
224 evaluate the scientific soundness of the chosen research using two tools. For more reliability, all of the
225 chosen publications were separately evaluated by two co-authors from different institutions using both
226 tools. In the event of a disagreement, a third reviewer was asked to evaluate the work.

227

228

229 **2.6 Data extraction and analysis**

230

231 The articles underwent evaluation and analysis. Focused efforts were made on particular studies that
232 addressed the study purpose. Reading the abstracts first, then the entire articles, allowed for the data
233 extraction. (in-depth). To determine the approach in selecting input and output for hospital DEA study,
234 content analysis was used in conjunction with quantitative and qualitative analysis. A data extraction
235 form with entries for year of publication, country of study, type of hospitals studied, number of
236 hospitals, number of observations (DMUs), model types, return to scale, model orientation, type of
237 efficiency measured, inputs and outputs, number of models tested, application of second stage analysis
238 in the study, and approach used in selecting inputs/outputs, was used to collect data from the selected
239 studies.

240

241

242 **2.7 Statistical analysis**

243

244 The agreement between two raters (co-authors) in evaluating the studies was measured using Intra-class
245 correlation (ICC). By comparing the variability of various evaluations of the same subject to the overall
246 variation across all ratings and all subjects, ICC evaluates the dependability of ratings. The evaluations

247 are quantitative. The ICC coefficient value for the Mitton et al.'s fifteen-point scale and Varabyova and
248 Müller economic evaluations and efficiency measurement are 0.956 and 0.984 respectively. No articles
249 were eliminated at this point because the review was in qualitative and quantitative, however articles
250 with high quality ratings were given more consideration in the data analysis and result interpretation.

251

252

253 **Results**

254

255 Eighty-nine papers that met the criteria for inclusion were all retrospective studies that were published
256 between 2014 and 2022. A summary of all the specifics of the listed research may be found in Appendix
257 A and Appendix B.

258

259

260 **3.1 Efficiency analysis**

261

262 Efficiency analysis in DEA focus on the data by measuring the performance set of DMUs. The
263 definition of DMU is generic and broad. In this review it focuses on the “hospital”. Technical
264 efficiency, scale efficiency, pricing efficiency, and allocative efficiency are the four main ideas of
265 efficiency [25]. While other describe efficiency as technical, pure, scale, allocative, cost, and
266 congestion. DEA able to perform efficiency analysis at single point of time and over time [26]. Thus,
267 the data can be cross sectional (single period) or longitudinal (panel data). In longitudinal analysis DEA
268 measure efficiency by two methods which are, Malmquist Productivity Index (MPI) and Window
269 Analysis (WA).

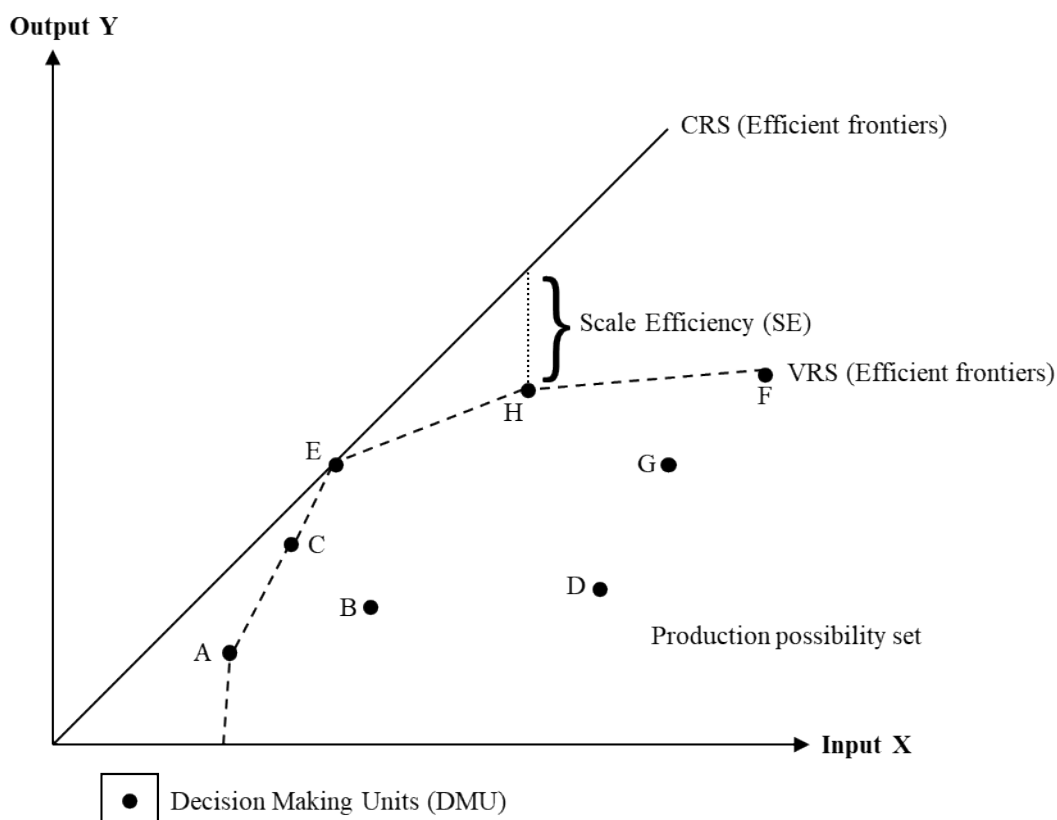

270 The majority of the papers that were included (29 of 89, 32.58%), evaluated hospital
271 performance solely on the basis of Pure Technical Efficiency (PTE) [46–74]. Pure Technical Efficiency

272 (PTE) is the effectiveness with which an input set is utilised to produce an output on the VRS frontier
 273 [50,69]. In other words, a hospital is considered technically efficient if it generates the greatest amount
 274 of output from the fewest number of inputs. The (overall) Technical Efficiency (TE) is the product of
 275 Scale Efficiency (SE) and PTE [75,76]. TE is the efficiency measured under the CRS production
 276 frontier. While scale efficiency measures how far a unit strays from an optimal scale (which is the area
 277 where there are CRS in the relationship between outputs and inputs) [77,78]. As a result, it can be
 278 written as:

279
$$\text{Technical Efficiency (TE), } \theta_{\text{CCR}} = \text{Pure Technical Efficiency (PTE), } \theta_{\text{BCC}} \times \text{Scale Efficiency}$$

280 The Fig 2 illustrates geometrically the concepts of efficiency measurement in DEA

281 **Fig 2. Concepts of efficiency measurement in Data Envelopment Analysis**

282

283

284 Twenty nine percent (26 of 89, 29.21%) of the included studies measured the (overall) Technical
 285 Efficiency (TE) [77–102] and 26.97% (24 of 89) [75,76,103–124] used TE, PTE and SE in their

286 evaluation. While the rest of the studies evaluated their efficiency by the combination of TE and PTE
287 and some not stated clearly the type of efficiency measured (for details see Appendix C).

288

289

290 **3.2 Model parameters**

291

292 Four considerations must be specified by researcher or user in order to apply DEA: the model type, the
293 technological assumption of the delivery process, the model orientation, and the input-output
294 combination [113,122]. This model can be further analysed or extended via second stage analysis or
295 integrated with other statistical analysis to attain better efficiency measurement, to explain the variation
296 or difference in organization performance or to evaluate the productivity of organization over certain
297 time [92,111,120]. The data type is also important, as it showed how the performance were analysed
298 over certain time period.

299

300

301 **3.2.1 Model type**

302

303 DEA has been applied to evaluating the performance of a wide range of entities engaged in a wide range
304 of activities in a wide range of circumstances. Thus, lead to many models and extensions to explain the
305 intricate and frequently unknowable relationships between the various inputs and outputs that are
306 involved in organization activities or productions [107,125]. The models described as basic DEA model
307 and extensions model. While others detailed the model as Radial, Non-Radial and Oriented, Non-Radial
308 and Non-Oriented, and Radial and Non-Radial [23,126]. The majority of the research that were included
309 used Radial DEA models (72 of 89, 80.90%) [46,48–52,54–62,65–77,79,80,82–86,89–94,96–100,102–
310 116,118–124,127–130]. BCC, CCR or combination of both models were the specific model utilized in

311 measuring efficiency via radial change of input and output values. In contrast, only seven studies
312 (7.87%) [47,53,63,64,95,101,131] used Non-Radial and Oriented model. While four studies (4.49%)
313 [81,87,88,125] used Non-Radial and Non-Oriented model. This Non-Radial model, instead of adhering
314 to a proportionate change of input/output, deals with slacks directly. One study used Radial and Non-
315 Radial [78] and one study applied combination of Radial with Non-Radial and Oriented model [117]
316 to measure efficiency. While four studies [132–135] did not clearly state the model used in their paper
317 (for details see Appendix D).

318

319

320 **3.2.2 Model orientation**

321

322 Orientation indicates the input or output orientation in measuring efficiency. In other words, either
323 output expansion or input decrease is the primary evaluation goal. More than half of the studies
324 (55.06%, 49 of 89) [46–48,50–54,58,60,64–69,71–73,75–77,80,91–94,96,98,99,103–107,109–
325 111,113–116,118,121,124,127,128,130,135] applied input-orientated DEA models. The researchers
326 indicated that the choice of input orientation was made to be in line with the fact that the majority of
327 healthcare units aim to minimize inputs given a goal level of output. In other words, the organization
328 had little or no control over the output [46,51,110]. About a quarter of the studies (25.84%, 23 of 89)
329 [49,55–57,59,61,62,70,74,79,82–86,102,108,112,117,119,122,123,134] expressed the opposite. The
330 organization should be able to produce more output given that the input is fixed and not easily
331 increase. Thus, output-orientated DEA models are more appropriate in their settings [79,83,84]. Five
332 studies (5.62%) [81,87,88,100,125] applied Non-Orientated DEA models, while three studies (3.37%)
333 [95,101,129] used the combination of both input & output orientated DEA models. The rest of the
334 studies [63,78,89,90,97,120,131–133] did not clearly state which orientation were used in their
335 measurement (for details see Appendix E).

336

337

338 **3.2.3 Return to scale assumption**

339

340 Regarding the return to scale assumption, about one third of the studies (35.96%, 32 of 89)
341 [75,76,79,92,102–125,127–130] applied combination of both CRS and VRS assumptions in evaluating
342 efficiency. The researchers seek to contrast the efficiency score measured in order to get better
343 understanding of the organization. Also gave further insight on how they can use each assumption in
344 improving their hospital services [102,109,114]. Another one third (32.58%, 29 of 89) [46–74] of the
345 studies utilized VRS assumption and implied that the outputs of organizations (DMUs) changes
346 significantly (increase/decrease) with inputs. While eighteen studies (20.22%) [77,80,82–86,89–
347 91,93,94,96–101] relied on the CRS assumption that the outputs of their organizations (DMUs) vary
348 (increase/decrease) in a manner similar to that of the inputs (for details see Appendix F).

349

350

351 **3.2.4 Input and output selection**

352

353 It is essential for a meaningful evaluation to choose appropriate inputs and outputs. Finding
354 characteristics that best describe the investigated process or production is one of the most crucial
355 responsibilities. All relevant resources should be incorporated into the inputs, and the outputs should
356 outline the organizations (DMUs) administrative goals [53,105]. The characteristics of suitable inputs
357 and outputs can vary depending on the situation. Although it is crucial to select the appropriate inputs
358 and outputs, data availability is also one of the considerations that need to be noted by the researcher.
359 There are recommendations have been set up to assist researchers in locating suitable measures
360 [77,132,134]. This will be discussed further as the main objective of this review.

361 There are classification of inputs and outputs to aid researchers in measuring efficiency.

362 Namely, capacity-related, labour-related, and expenses-related. Or capital investment, labour and

363 operating expenses. Some researcher further identified this classification into sub-categories. The
 364 outputs can be classified as inpatient services, outpatient services and effectiveness (quality)
 365 component. While other categorized outputs into activity-related (inpatient and outpatient) and quality-
 366 related (effectiveness dimension) [20,21,25,32]. In this review we classified and sub-classified the input
 367 & output as displayed in Table 1 and the details of each sub-classification frequency distribution and
 368 percentages as in Table 2 and Table 3.

369

370

371 **Table 1. Input and Output Categories used in the studies**

Input	Percentage (%)	Output	Percentage (%)
Capacity-related:	30.06	Production-related	94.30
Beds	24.85	Inpatients	42.62
Capital assets	5.21	Outpatients	24.83
		Adjusted scores	13.42
Cost-related:	15.34	Combination	12.08
Total costs	7.06	Monetary	4.70
Medication & service costs	5.21	Imaging & Laboratory	2.35
Labour costs	2.15		
Equipment costs	0.92	Quality-related	5.70
		Patients	72.22
Staff-related:	52.76	Staffs	27.78
Doctors	17.18		
Nurses	13.19		
Clinical staffs	10.74

Mortality rate (infant, adult, specific diseases)	9	50.00
Revisit rate (outpatient, emergency)	3	16.67
Number of students	2	11.11
Patient's satisfaction score	1	5.56
Staff's satisfaction score	1	5.56
Number of medical inquiries	1	5.56
Management's score	1	5.56

378

379

380 **3.2.4.1 Capacity-related input**

381

382 Most frequently, the size, capacity, or functioning of a hospital as a health service is determined by the
383 number of fully staffed hospital or operational beds. 75 of the 89 (84.27%) studies included the number
384 bed (i.e., general, ICU, special) as input in their analysis [48–55,57–62,64–74,76,78–93,95–101,103–
385 109,112–116,118,119,121–125,128–131,133–135]. Seven of these 75 studies (9.33%) utilized
386 variation of multiple beds as their inputs either by type of bed, bed cost, or ratio of bed
387 [61,66,71,78,98,101,129]. While 12 of these 75 (16.00%) studies combine both beds and capital assets
388 as their capacity-related input [70,78,85,89,90,101,103,106,109,122,125,133]. One study only used
389 capital assets as their input but combine with cost-related assets, this may explain why this study did
390 not use beds as part of input like other studies [56]. The most prevalent capacity-related input in the
391 studies was the number of general beds, followed by the number of facility types and finally the number
392 of medical equipment.

393

394

395 **3.2.4.2 Cost-related input**

396

397 Among the listed research, cost-related inputs were the least utilised inputs. Out of the 89 studies, only
398 31 (34.83%) applied in the studies. Three of these 31 studies, specifically used cost-related inputs only
399 in their research [63,102,120]. While majority of these 31 studies (90.32%) utilized combination of
400 either capacity-related inputs and staff-related inputs in their research [46–48,51,56,62–64,70,75–
401 79,83,91,94,95,101,102,109,111,112,114,116,120,125,129,130,132,133]. The most often used cost-
402 related input in the research was the total operating cost, followed by the fixed costs, finally both service
403 costs and consumable costs.

404

405

406 **3.2.4.3 Staff-related input**

407

408 Almost all of the studies utilized staff-related inputs (93.26%, 83 of 89) [46–55,57–62,64–90,92–
409 119,121–125,127–131,134,135]. Out of these 83 studies, two studies combined used the number of
410 staff (staff-related) and the labour cost (cost-related) their input [75,78]. The six studies that did not
411 included staff-related input, substitute cost-related (either labour cost or operating cost) as their proxy
412 in their analysis [56,63,91,120,132,133]. The staff-related input values varied among the observed
413 papers. Most of the studies used arithmetic number (actual), followed by Full Time Equivalent and ratio
414 of specific value. The number of doctors, followed by number of nurses and number of clinical staffs,
415 was the most prevalent staff-related input in the studies.

416

417

418 **3.2.4.4 Production-related output**

419

420 Looking at the output, almost all of the studies used production-related output (98.88%, 88 of 89) [46–
421 92,94–125,127–135]. Eight studies applied combination of production-related output with quality-
422 related output [61,73,84,87,95,98,128,133]. The number of outpatients were the most prevalent
423 production-related output among the studies. The number of inpatients (admission, discharge) were the
424 second most prevalent, followed by the total number of operations and the number of inpatients.

425

426

427 **3.2.4.5 Quality-related output**

428

429 The application of quality-related outputs was varied and were not prominent as the production-related
430 output. Nine studies used quality-related output [61,73,84,87,93,95,98,128,133]. One study specifically
431 applied only quality-related in their research, which match with the researcher objective [93]. The most

432 often applied quality-related output was mortality rate (infant, adult, specific diseases), followed by
433 revisits rate (outpatients, emergency) and number of students.

434

435

436 **3.2.5 Extended analysis & data type**

437

438 Among the studies, 80 (89.89%) conducted extended analysis in their research [46–56,58–64,66–
439 69,71–77,79–94,96–98,101–116,118–125,128–135]. The type of data applied were almost equally
440 distributed among the studies 51 (57.30%) [47,49,52,58–60,67,70–73,75–77,79,80,83–
441 85,88,91,92,94,96,97,100,101,103,105–109,111,112,114–116,120–122,124,125,127,129–135] used
442 panel data and 38 (42.70%) [46,48,50,51,53–57,61–
443 66,68,69,74,78,81,82,86,87,89,90,93,95,98,99,102,104,110,113,117–119,123,128] used cross
444 sectional data in their research. Forty extended analyses were identified within the included studies.
445 Each study may apply one or multiple extended analysis (some mentioned as “stages”). Out of 80
446 articles that applied extended analysis, 46 studies integrated two or more extended analysis in their DEA
447 measurement [46,47,51–54,58,60,63,64,67,68,71,73–75,77,79,80,83–86,88,91–94,96,101,102,107–
448 109,114–116,119–121,128,130,131,133–135]. The maximum number of extended analyses observed
449 within the studies were five [67,92,94]. The main extended analysis used in hospital efficiency
450 assessment was regression analysis (29.11%, 46 of 158) followed by production function analysis
451 (16.46%, 26 of 158), statistical analysis (15.82%, 25 of 158) and resampling methods (15.82%, 25 of
452 15). The complete list of the specific analysis to each classification is presented in Table 4.(for details
453 see Appendix B)

460

461 **3.3 Approach in selection of input and output**

462

463 In selecting input and output for DEA with regards to hospital, various approaches or method adopted

464 by the researchers. All the 89 studies used previous study or literature review as a sole basis or part of

465 their method in selecting input and output. Few studies precisely mentioned using local DEA efficiency

466 study at their respective country as the reference for input and output selection. Some of the studies

467 used combination of approaches. 63 studies (70.79%) used only literature review as their approach in

468 selecting the input and output [46–48,50–55,59,60,62,64–78,81,82,85,86,89–92,94,96–

469 98,101,103,105,108,110,111,113,115–122,124,125,127,128,130,132–135]. While the rest used

470 literature review in combination with other approaches. The combination was varied among the studies.

471 The dominant combination approach identified was literature review & data availability (13.48%, 12 of
 472 89) [56,57,79,83,104,106,107,112,114,123,129,131], followed by literature review & systematic
 473 method (5.62%, 5 of 89) [58,61,84,102,109] and literature review & DMU limitation (5.62%, 5 of 89)
 474 [49,80,87,95,99]. The maximum combination was four, which one study mentioned in their article
 475 [88]. The complete list of the specific approach presented in Table 5
 476

477 **Table 5. Classification of approach in selection of input and output**

Approaches	N	%
Literature review	63	70.79
Literature review	60	67.42
Local studies literature review	3	3.37
Literature review & data availability	12	13.48
Literature review & data availability	11	12.36
Local studies literature review & data availability	1	1.12
Literature review & systematic methods	5	5.62
Literature review & Delphi method	2	2.25
Literature review & Promethee method	1	1.12

Literature review, data availability, expert judgement & DMU limitation	1	1.12

478

479

480 **Discussions**

481

482 Anyone unfamiliar with the subject will find the DEA universe's size to be intimidating. It is practically
 483 impossible to read every previous study to gain knowledge from their experiences, even when limiting
 484 the literature to healthcare applications. To accomplish the goals of this study, 89 studies underwent
 485 thorough scrutiny. Nunamaker published the first health application utilising DEA to investigate

486 nursing services, and Sherman published the second DEA paper to assess the medical and surgical
487 departments of seven hospitals [136,137]. Since then, Over the past forty years, DEA applications in
488 health have evolved. The calibre of the studies has increased as access to resources and information
489 technology has advanced [23,25,138,139].

490

491

492 **4.1 Approaches taken by researchers in selection of input and** 493 **output of DEA for hospital efficiency measurement** 494

495 DEA is frequently used to assess the relative effectiveness of a group of institutions like businesses,
496 hospitals, universities, and government agencies. In conventional analysis, such judgements might take
497 many different forms. In hospitals setting, production of healthcare is distinct from manufacturing.
498 Raw materials are physically transformed into finished goods in a conventional factory. There is no
499 participation or co-production because the customer is not present. It is challenging to identify the
500 appropriate variables because patients are involved in the process. Furthermore, in healthcare it is not
501 just about performance and efficiency, the effectiveness (quality component) is equally important
502 [87,93,128]. Although there is no standard set of input and output in DEA studies, there are several
503 guidelines, analytic procedures or principles to help researchers choose the best variables in their study
504 [140–144].

505

506

507 **4.1.1 Literature review** 508

509 A literature review is still used today and is thought to be one of the most effective techniques to place
510 a study within the body of knowledge. Be it in the form of narrative review, rapid review, scoping
511 review or systematic review. It acts as a foundation or building block for knowledge advancement,

512 theory development, and identify areas of improvement [145–147]. Literature reviews were the most
513 prevalent approach for selection of input and output for hospital efficiency study using DEA. Our
514 reviews showed that all studies applied literature review as sole approach or part of combination
515 approach. None of the studies stated exactly on the methodology of literature review done except few
516 studies that define they only taken studies from their local country [50,86,105,123]. The reason for
517 researchers to specify this is one of their objectives was to compare their findings with local previous
518 studies. DEA is a non-parametric technique that relies entirely on the observed input-output
519 combinations of the sampled units and do not necessitate any presumptions regarding the functional
520 structure of the link between inputs and outputs [77,115]. Thus, this gives the advantage for researchers
521 to select input and output based on literature review as DEA will measure the efficiency value which
522 depend on the study objective even though it might give a less significant value [140,143].

523

524

525 **4.1.2 Data availability**

526

527 DEA relies on homogeneity of the unit's assessment. The DMU are assumed to be producing similar
528 activities or product with similar resources and technology under the same environment. Thus, a
529 common set of similar input and output can be defined . With large datasets in the hospitals, there are
530 needs some consideration to be done. This includes, the data quality, data availability, data scale and
531 types of data [140,142]. Within the studies it is found that, although the researchers applied literature
532 review in selection of input and output, they mentioned it is subjected to data availability. Few methods
533 identified on how the researchers overcome this limitation. First, specifically mentioned that the study
534 only collected data which is available within their scope [88,104,131]. Second, some study omitted the
535 DMU with incomplete data and focus their analysis on DMU with complete data [79,106]. This is one
536 of the advantages of DEA, as DEA only measure the relative efficiency or the production frontier of
537 the units include in the analysis. Third, the researcher applied DEA within specific period of data

538 availability to ensure the desired input and output are complete [56,114]. There is method in dealing
539 with missing of incomplete data in DEA, but non-of the studies reviewed applied of mentioned on it
540 [148,149].

541

542

543 **4.1.3 Systematic method**

544

545 In determining the input and output, researchers can list as many as possible factors. This may result in
546 two major issues. One there will be a long list of input and output and second, if there is limited number
547 of DMU the discriminating power for DEA to measure the efficiency will be affected [140,143]. It is
548 important to choose the important variables and at the same time able to measure the efficiency
549 accordingly. Researchers has been incorporating systematic procedure to judge this process. In the
550 review, four systematic approaches have been identified which are Delphi method, Preference Ranking
551 Organization METHod for Enrichment of Evaluations (PROMETHEE), Bibliometric analysis, and
552 Variance filter [49,58,61,102,109]. The Delphi method is a methodology used in research models that
553 is centred on gathering the most trustworthy consensus of expert opinion for challenging situations.
554 This forecasting method was first presented in the 1950s by Olaf Helmer and Norman Dalkey of the
555 Rand Corporation. It is based on the responses to multiple rounds of questionnaires sent to a panel of
556 experts [150,151]. The Delphi method is a well-known method for researchers to use in measuring
557 efficiency using DEA in various area [152–154]. In 1982, the PROMETHEE method was created for
558 the first time, and in 1985 it underwent further development [155–157]. It is currently regarded as a
559 widely used and usable Multiple Criteria Decision Aid tool including application with DEA [158–161].
560 In comparison to many other MCDM methods, PROMETHEE is a ranking system that is thought of as
561 being simple in conception and computation. It includes weights indicating the relative importance of
562 each criterion as well as a preference function linked to each criterion. One of PROMETHEE's key
563 applications, the ability to select, is used to help the decision-maker select the best possibilities for

564 assessing hospital performance. This gives the ability for researchers to integrate PROMETHEE in
565 DEA application [162–165]. The term bibliometric was coined by Pritchard in 1969. It is an “application
566 of mathematics and statistical methods to books and other media of communication”. In other words,
567 bibliometric analysis evaluates the properties of bibliographic information or metadata from database
568 or collection of documents. With a purpose to increase knowledge of the topic being studied [166,167].
569 Researchers applies bibliometric analysis for various objectives, to identify new trends in journal
570 performance, collaborative styles, and research components; to lay the groundwork for the new and
571 significant advancement of a field; and to making sense of massive amounts of unstructured data in a
572 systematic manner in order to interpret and map the cumulative scientific knowledge and evolutionary
573 nuances of established domains [168,169]. Thus, the usage of bibliometric analysis is applicable in
574 identifying the input and output in DEA studies with regards to the field of healthcare especially
575 hospital. Variance filter is one of the filter methods in Feature Selection. It is the process of deciding
576 which traits are most crucial and keeping them. It helps to lessen noise, lower the model's computational
577 expense, and occasionally boost model performance. In this case which in the crucial input and output
578 listed by the researchers [170,171]. By using the Variance filter (Feature Selection), researchers have
579 the ability to remove variables (input or output) which have little or no impact in the measurement of
580 DMUs efficiency. This method is well accepted in the application of DEA studies [102,172–174].

581

582

583 **4.1.4 Expert judgement**

584

585 The refinement of variables selection (input and output) can be decided by the judgement of expert
586 which can be the researcher, the stakeholders or the decision makers. The value judgment can be said
587 as “logical constructs used in efficiency assessment research that reflect the Decision Makers' (DM)
588 preferences during the efficiency assessment procedure”. This includes the decision to omit variables
589 or the put zero weight in the variable [143,175]. This is again the ability of DEA to measure efficiency

590 based on the needs and requirement of the decision makers. Although it can lead to problem such as
591 bias in selection, omission of input or output that may have significant impact on the efficiency
592 measurement, or putting the wrong weight for input and output. The incorporation of expert or value
593 judgment are motivated by the objective of researchers. There are advantages and disadvantages with
594 respect to the application of DEA. It is important to understand the managerial and statistical implication
595 of applying value judgement in the selection of input and output [176].

596

597 **4.2 Common DEA model parameters in hospital efficiency** 598 **evaluation.**

599

600 **4.2.1 Model type**

601

602 The application of DEA has been undergoing extensive developments and evolution over the time.
603 Thus, numerous models exist to measure efficiency from the basic model to the very specific application
604 of DEA. In this review we found that 80.90% of the included studies applied Radial DEA models.
605 Which includes BCC model (Banker, Charnes and Cooper), CCR model (Charnes, Cooper and Rhodes),
606 and combination of both models. These findings are similar with some of the previous review in
607 healthcare setting [17,21,33]. A Radial DEA model means the major concern is a proportionate change
608 in the input/output values; as a result, slacks (input excesses and output shortfalls still present in the
609 model) are ignored or treated as optional. Although there are limitations with radial model, researchers
610 still use this model as it is a basic model, simple to understand and easier to apply without much
611 requirement on the production criteria of the DMUs [48,80,177].

612

613

614 **4.2.2 Model orientation**

615

616 The selection of DEA orientation depends on several factors or arguments. It can be what the decision
617 maker can control more effectively, what is the nature of the production, or what is the researcher
618 objective from the model [25,32,178]. Healthcare organizations or hospitals in general have limited or
619 less control over their outputs. But it does not mean a DEA efficiency evaluation in hospital must be in
620 input orientation. Our review, found that 55.06% of the articles used input-oriented DEA models.
621 Previous studies also shown similar findings albeit in different proportion [17,20,21]. This can be seen
622 as researchers or hospital managers consider that minimising inputs given a goal level of outputs is
623 more suited for measuring hospital efficiency since hospital have limited control over their outputs.

624

625

626 **4.2.3 Return to scale assumption**

627

628 Since the development of the two fundamental models, there has been debate on which is better (and,
629 consequently, whether to assume CRS or VRS). Hospital managers seek the best method evaluations to
630 measure which input or output are improving their organization's efficiency. The selection of return to
631 scale with regards to hospital depends on the size of hospital [65], the organization factors [76,91], the
632 flow of process of input and output [111,127], technological involvement [82,122], or other related
633 factors. It is crucial to keep in mind that the adoption of an improper return to scale may result in an
634 excessively constrained region of the search for effective DMUs. Thus, the researcher can consider to
635 explore both assumptions to understand the implications of using either one [179]. In the review, we
636 observed most of the studies applied both assumption for comparison reason (35.96%) and followed by
637 VRS assumption (32.58%). In past review, there is a shift towards using CRS to VRS assumption in
638 application of DEA [20,21,33]. It may be said that the majority of assessments of hospital efficiency
639 were made with of view economies of scale exists and that they considered the production function of
640 healthcare to have non-proportionality shifts between inputs and outputs.

641

642

643 **4.2.4 Inputs and outputs choice**

644

645 We already covered the main objective of this review to look at the approaches taken by researcher in
646 selection of their inputs and outputs. The selection of appropriate inputs and outputs is essential for the
647 analysis of DEA to be useful, and we cannot emphasise this point enough. As many previous reviews
648 stated, the quality and quantity of these indicators play a major role in the DEA efficiency analysis
649 [15–18,20,21,30,33]. We observed in term of inputs, majority of the studies (52.76%) used staff-related
650 input as part of the variables in efficiency measurement. This is not surprising considering human
651 resource plays an important role in any organization including hospital. This finding is similar to
652 previous study of DEA and even in other performance related studies on healthcare service [180,181].
653 The unit of analysis of staff-related factors depends on how the organization functioning. In the review
654 mainly we noticed to types either actual number of staff or full time equivalent. The spectrum of staff
655 types was various from the clinical staff to non-clinical staff (Appendix A and B). If we looked at the
656 sub-type of inputs, the number of general beds had the highest prevalence (74.49%). Hospital beds is
657 the basic capital-related input for a hospital. It is one of the key indicators that use for hospital
658 performance, hospital capacity, hospital capability even in comparing health service between country
659 [182–184]. As for the outputs, in general we observed most researchers applied production-related
660 outputs compare to quality related. This occurrence may be said due to it is easier to measure
661 production-based data and give the stakeholders a relatively target to improve upon it. While
662 effectiveness (quality) is not something that healthcare managers would trade-off to improve the
663 efficiency [25,185]. In the review, the number of inpatients, number of our patients and number of
664 operations were the common outputs applied. The widespread use of these variables was no surprised,
665 as it is the bread and butter of hospital services.

666

667

668 **Limitation & conclusion**

669

670 This is the first in-depth systematic review examining the approach in input-output selection of DEA
671 efficiency measurement in hospital. As far as we know, no research has previously examined this. That
672 is the main purpose of this systematic review to provide an overview of the existing approaches. In
673 addition to serve as an update on DEA models that are currently applied for hospital efficiency
674 evaluation. Eighty-nine articles were reviewed and assessed thoroughly with the mentioned objectives.
675 Literature review was dominantly utilized as an approach for selection of inputs and outputs in DEA.
676 Researchers used literature review as a sole method or combined with other approaches to make the
677 selection more robust and vigorous. As the selection of variables in DEA study are very important and
678 may cause different results in efficiency measurement [140]. There is no specific approach or methods
679 that can be point out in selection of variables (input-output) in DEA. That is the advantage and also
680 weakness of DEA [186–188]. It gives the ability for researchers and stakeholders to evaluate efficiency
681 of their organization based on their preference but they need to be aware of the limitation of DEA and
682 potential pitfall [140,143]. This review focus on approaches in hospital settings, this may limit our
683 findings. There might be other approach or method that is use to choose input and output for DEA study
684 in another field or approaches based on other perspectives [189]. The approach in input-output selection
685 should be identified given the ongoing aim of researchers and healthcare professionals to improve
686 healthcare efficiency assessment. It is crucial to consider past, present, and potential developments on
687 this subject in the DEA literature because it plays a vital role in DEA studies. As for the DEA models
688 parameters, there is no evidence of one best model or one fits model as almost all models had been
689 utilized more than twice (Appendix A and B). Our review provides some guideline and methodological
690 principle on DEA study based on established literature. This hopefully will shed some light to hospital
691 managers, healthcare workers, policy makers even students on evaluation of efficiency by DEA.

692
