

12 **Abstract**

13 The current study investigates the seroprevalence of the Hepatitis C Virus (HCV) among sex workers in
14 Pakistan, a task made challenging due to social and cultural barriers. Our primary objectives were to gauge
15 the extent of HCV exposure in this marginalized group, identify disparities in seroprevalence between
16 sexes, and examine the association between seropositivity and various demographic and risk factors. We
17 enrolled 1,000 participants, predominantly male (87.7%) and female (12.3%) sex workers. The majority
18 fell within the 26-35 years age category (39.9%). A significant proportion (47.1%) had not received formal
19 education. Overall, HCV antibodies were found in 15% of the participants. Disparities were evident with a
20 seroprevalence of 13% in male sex workers and a significantly higher 31% in female sex workers. HCV
21 seropositivity increased with age, with female sex workers showing a sharper rise. A link between levels
22 of formal education and HCV seroprevalence was observed, with female sex workers consistently
23 exhibiting higher seroprevalence across educational levels. Risk factors such as shaving practices, sharing
24 of blades, surgical history, and other medical exposures were assessed, revealing higher HCV seropositivity
25 rates among those exposed, especially pronounced among female participants. Despite the societal
26 challenges, this research paves the way for future investigations and interventions tailored to this
27 population's unique needs and vulnerabilities.

31 **Introduction**

32 Hepatitis C virus (HCV) infection remains a significant global health concern, exhibiting considerable
33 prevalence variations across diverse populations and geographical regions (1-5). This variability is
34 attributed to multiple factors, including disparities in socioeconomic conditions, accessibility to healthcare
35 services, and the availability of harm reduction programs (6, 7). Predominantly, HCV infection affects two
36 age demographics: individuals aged 20-40 years and those over 50 years (8-11).

37 Transmission of HCV is primarily through exposure to contaminated blood, occurring through means such
38 as contaminated surgical instruments, blood transfusions, and sharing needles or syringes (2, 12). While the
39 risk of sexual transmission is generally lower, it is notably elevated among certain populations, including
40 sex workers (13-15), due to risk behaviors that facilitate acquiring and transmitting these viruses through
41 sexual and parenteral routes (2, 13).

42 Previous research shows significant disparities in HCV prevalence among sex workers across various
43 regions and demographics. For instance, a study conducted in Glasgow highlighted an alarming 81% HCV
44 seroprevalence among female sex workers who inject drugs, significantly surpassing the rates for general
45 injecting drug users in Glasgow and any recorded in the UK from 1991 to 2005 (15). Conversely, a
46 Canadian study reported a baseline prevalence of 42.7% among female sex workers. This study also showed
47 that HCV incidence was highest among women who inject drugs. They also reported higher HCV
48 prevalence among women living with sexually transmitted infections or HIV. Moreover, the use of non-
49 injection stimulants was found to be associated with HCV seroconversion (14). Other studies also reported
50 varying prevalence rates and associated risk factors, emphasizing the diverse nature of HCV prevalence
51 among sex worker populations globally (16, 17).

52 In Pakistan, a nation confronting one of the most substantial burdens of HCV, the vulnerability of male and
53 female sex workers is accentuated. Nevertheless, a pronounced void exists in exhaustive research dedicated
54 to these demographics, notably in an environment characterized by significant impediments to education

55 and healthcare. With a staggering approximation of 10 million individuals living with HCV in Pakistan, the
56 dearth of intricate data on HCV seroprevalence within the sex worker community is palpable (18-20).
57 To bridge this informational gap, the presented work aimed to study the HCV seroprevalence among male
58 and female sex workers and examine the associated risk factors. The undertaking of research within such
59 marginalized communities as the sex workers in Pakistan mandated an approach imbued with collaboration
60 and empathy. To this end, we established a partnership with *Dostana*, an organization steadfastly dedicated
61 to the empowerment and health advocacy of vulnerable communities. This alliance enabled an effective
62 and considerate engagement with the sex worker community in Pakistan, ensuring the study was conducted
63 with due deference while addressing the distinctive needs and challenges faced by this community.

64 **Methodology**

65 **Research Design and Participant Selection**

66 This cross-sectional study determines the seroprevalence of the Hepatitis C Virus (HCV) among sex
67 workers in Pakistan. A total of 1000 participants, male and female, were included in this study. The
68 inclusion criteria stipulated that participants must be sex workers aged 15 years or older and possess
69 proficiency in Punjabi or Urdu. Participants were recruited through the *Dostana Male Health Society*, a
70 recognized society that addresses key populations' healthcare concerns. Due to Pakistan's societal and
71 cultural barriers, engaging with individuals in these marginalized communities is challenging. As a solution,
72 community members were educated and guided to gather data from the sex workers population enlisted
73 through *Dostana*.

74 The data collection process involved structured interviews. After the necessary training, data enumerators
75 administered the structured questionnaires through one-on-one interviews. This method ensured that the
76 process was consistent, comprehensive, and aimed at minimizing potential bias or misinterpretation of the
77 questions. The data were collected on demographic characteristics, common risk factors, and history of
78 HIV.

79 **Ethical Considerations**

80 The study protocol is reviewed and approved by the Bioethics Committee of the Cancer Research Centre,
81 University of the Punjab. All participants provided informed written consent before participating in the
82 study. The study is conducted following the Declaration of Helsinki.

83 **Serological Testing**

84 Blood samples are collected from participants for serological testing. The presence of HCV antibodies is
85 determined using the SD BIOLINE HCV Hepatitis C Virus Antibody Test. All tests are conducted in a
86 certified laboratory following standard procedures.

87 **Statistical Analysis**

- 88 Descriptive statistics are used to summarize the demographic characteristics of the participants and the
- 89 Prevalence of HCV. All analyses are performed using MS Excel.

90 Results

91 Demographic Characteristics of the Study Participants

92 The study comprised a total of 1000 participants, with a significant majority being men (87.7%) and a
93 smaller proportion being women (12.3%) (**Table 1**). The participants spanned a wide age range, with the
94 largest group falling within the 26-35 years category (39.9%). This was followed by the 18-25 years age
95 group (25.0%), the 36-45 years age group (20.8%), those older than 45 years (13.3%), and a small fraction
96 under 18 years (1.0%) (**Table 1**).

Demographic Criteria	Number of Participants		
	Total	Men	Women
Number of Participants	1000	877	123
Age Distribution			
<18	10	10	0
18-25	250	238	12
26-35	399	350	49
36-45	208	180	28
>45	133	99	34
Years of Formal Education			
0	471	399	72
≤8	229	209	20
9-12	229	206	23
>12	71	63	8
Marital Status			
Married	611	523	88
Single	388	353	35
HIV Status			
HIV Positive	1	1	0
HIV Negative	998	876	122

107 Regarding years of formal education, a significant proportion of the participants had not received formal
108 education (47.1%). Those with eight years or less of formal education constituted 22.9% of the participants,
109 while those with 9-12 years also comprised 22.9% of the total. A small fraction of the participants had more

110 than 12 years of formal education (7.1%). Most participants were married (61.1%), while a substantial
111 proportion were single (38.8%) (**Table 1**).

112 The study also evaluated the HIV seroprevalence of participants. The vast majority were found to be HIV
113 negative (99.8%), with only one individual (0.1%) being HIV positive.

114 **HCV Seroprevalence of the Study Participants**

115 Next, the seroprevalence of HCV was assessed in this cohort of sex workers. Overall, HCV antibodies were
116 found in 15% of the population, suggesting that these individuals had been exposed to the virus at some
117 point (**Fig 1a**).

118 **Fig 1. Prevalence of HCV seropositivity among Pakistani Sex Workers.** (a) A pie-chart displaying
119 seroprevalence of HCV in overall study population (n=1000). (b) A pie-chart displaying seroprevalence of
120 HCV in male sex workers population. (c) A pie-chart displaying seroprevalence of HCV in female sex
121 workers population.

122 When the data is analyzed based on sex, notable disparities become evident. Among male sex workers, the
123 seroprevalence of HCV was 12%, whereas a significantly higher seroprevalence of 31% was observed in
124 female sex workers (**Fig 1b-c**).

125 This difference in seroprevalence between male and female sex workers indicates a higher likelihood of
126 past or present HCV infection among the female participants. However, it is imperative to note the
127 significantly larger male sample size when interpreting these findings.

128 **Association of HCV seroprevalence with selected demographic** 129 **characteristics**

130 Among participants aged less than 18 years, there were no positive cases of HCV detected, however, this
131 age group only included male participants (**Fig 2a-c**). In the age group of 18-25 years, HCV seropositivity

132 was relatively low in both males (6.4%) and females (8.3%). The seropositivity percentage gradually
133 increased with age in both sexes. In the 26-35 age bracket, HCV seropositivity increased to 12.8% in males
134 and 14.3% in females. A more pronounced rise in seropositivity was observed in the 36-45 years age group,
135 with rates reaching 23.6% in males and 53.6% in females. Similarly, in the age group over 45 years, the
136 seropositivity rate was 22.6% for males and 44.1% for females. These data suggest that HCV seropositivity
137 increases with age in both sexes, with female sex workers showing a sharper rise and overall higher
138 seroprevalence than their male counterparts.

139 **Fig 2: Prevalence of HCV seropositivity and associated risk factors in Pakistani sex workers**
140 **population. (a)** Age-adjusted HCV seroprevalence in overall sex workers population **(b)** Age-adjusted
141 HCV seroprevalence in male sex workers population **(c)** Age-adjusted HCV seroprevalence in female sex
142 workers population **(d)** Education-wise HCV seroprevalence in overall sex workers population **(e)**
143 Education-wise HCV seroprevalence in male sex workers population **(f)** Education-wise HCV
144 seroprevalence in female sex workers population. The total number of sex workers in each age **(a, b, c)** and
145 education **(d, e, f)** groups are plotted on left y-axis and represented as verticle gray bars and HCV
146 seropostivity percentage is plotted on right y-axis and represented as a yellow stacked line.

147 Our data reveal a link between levels of formal education and HCV seroprevalence among the sex workers
148 in our study. The HCV seroprevalence was 14.2% for participants without formal education **(Fig 2d)**.
149 Among those with ≤ 8 years of education, the seroprevalence rose slightly to 17.0%. For individuals with
150 9-12 years of education, the seroprevalence dropped to 13.1%. Interestingly, participants with more than
151 12 years of education had a seroprevalence of 14.1%.

152 On analyzing the data based on sex **(Fig 2e-f)**, it was noted that male sex workers with no education had a
153 lower seroprevalence of HCV at 12.0%, whereas the figure for their female counterparts was considerably
154 higher at 26.4%. In participants with ≤ 8 years of education, the seroprevalence was 14.4% for men and
155 sharply increased to 45.0% for women. Among individuals with 9-12 years of formal education, the

156 positivity rate dropped to 11.2% in men and 30.4% in women. For those with >12 years of education, the
157 seroprevalence was lower in men (11.1%) compared to women (37.5%).

158 Among married male sex workers, the seroprevalence was 15.1%, whereas, for single males, it was
159 significantly lower at 8.2% (**Table 2**). On the other hand, among female sex workers, married individuals
160 showed a considerably higher seroprevalence at 35.2%, compared to single females who had a
161 seroprevalence of 20.0%.

Table 2: Marital Status-Based Analysis.

Sex	Marital Status	Total Participants	Positivity %
Male	Married	523	15.10516
Male	Single	353	8.215297
Female	Married	88	35.22727
Female	Single	35	20

162

163 **Identified Risk Factors and Their Relationship to HCV**

164 **Seroprevalence**

165 Next, we analyzed the impact of Identified risk factors on HCV seroprevalence in male and female sex
166 workers (**Table 3**). In the context of shaving practices, individuals shaving at home had a higher overall
167 HCV seropositivity of 18.97% compared to those using salon services (12.62%) or both (13.27%). This
168 trend was consistent among men, with 10.81% positivity in those who shaved at home versus 12.58% and
169 13.54% for those who used salon services and both, respectively. However, for women, the pattern
170 diverged. Women who shaved at home had a significantly high HCV seropositivity of 33.33%, while
171 women who used salon services showed seropositivity of 14.29%.

172

173

174 Sharing of blades revealed a slightly higher overall HCV seropositivity among individuals men who shared
 175 blades had significantly higher seropositivity (20.51%) than those who did not (11.93%). For sharing
 176 toothbrushes, the overall HCV seropositivity was lower in those who shared (13.51%) than those who did
 177 not (14.64%).

178 History of surgery showed a pattern where individuals with a surgical history had higher overall HCV
 179 seropositivity (18.67%) than those without (13.88%). This was mirrored in men with a history of surgery
 180 (13.87%) versus those without (12.03%). However, among women, a striking difference was observed.
 181 Women with a surgical history exhibited an alarmingly high HCV seropositivity rate of 69.23%, whereas
 182 women without a surgical history demonstrated a seropositivity rate of 26.36%.

183 The pattern of other risk factors such as blood transfusion history, history of injections, dental procedures,
 184 hospitalization, and drug abuse revealed similar patterns. All risk factors showed higher HCV seropositivity
 185 rates among those exposed to the risk factor, with the differences being more pronounced among women
 186 compared to men. Notably, these differences among women should be interpreted with caution due to the
 187 smaller sample sizes.

188 **Discussion**

189 The presented work studied the seroprevalence of the Hepatitis C Virus (HCV) among sex workers in
190 Pakistan. This work aimed to examine the extent of HCV exposure within this marginalized community,
191 identify any disparities in seroprevalence between sexes, and study the association of seroprevalence with
192 various demographic characteristics and risk factors. Our study population predominantly consisted of men
193 (87.7%), with women making up 12.3%. The overall seroprevalence of HCV antibodies, indicative of
194 exposure to the virus, was 15%. Notably, a marked gender disparity was observed, with male sex workers
195 exhibiting a seroprevalence of 12%, while their female counterparts showed a significantly higher
196 seroprevalence of 31%. We also found variations in seroprevalence across different age groups, educational
197 levels, and marital statuses. It was observed that increasing age, lower education, and marriage were
198 associated with higher seroprevalence.

199 Studies focusing on HCV seroprevalence among sex workers have yielded diverse results. For example,
200 research conducted in Thailand (21) revealed a relatively low HCV prevalence of 2.3% among migrant sex
201 workers, contrasting sharply with a Glasgow-based study (15) that reported a striking 81% HCV
202 seroprevalence among female street sex workers who inject drugs. Meanwhile, a Canadian study (14)
203 documented a baseline prevalence of 42.7% among female sex workers. A study from Brazil [4] also
204 indicated a higher exposure prevalence to HCV, at 7.7%, among female sex workers. These findings
205 underscore the significant variability in HCV seroprevalence across different regions and populations of
206 sex workers, shedding light on the impact of various risk factors, demographic characteristics, and regional
207 healthcare infrastructures.

208 Our study found pronounced disparities in HCV seroprevalence between male and female sex workers.
209 This finding aligns with existing literature documenting elevated rates of HCV seroprevalence among
210 female sex workers (14). The heightened vulnerability of female sex workers is often a byproduct of
211 precarious working conditions, limited access to healthcare, and an increased likelihood of injecting drug

212 use—each a significant contributor to elevated HCV risk (17). The intersection of sex work and drug use
213 is particularly accentuated among female sex workers (14, 17), amplifying their susceptibility to HCV
214 infection. The multifaceted, gender-specific risks inherent in sex work necessitate the development of
215 tailored interventions and harm reduction strategies. These strategies should address the unique needs and
216 challenges faced by female sex workers, particularly in enhancing access to HCV prevention and healthcare
217 services.

218 Several studies have reported high HCV seroprevalence among men who have sex with men (MSM) (22-
219 24). However, only a few studies have undertaken a comparative analysis of sex-based differences among
220 sex workers (25, 26). There is a pressing need for additional research to further elucidate the variations in
221 HCV prevalence rates based on gender within the sex worker population.

222 We observed an increase in HCV seropositivity with advancing age, particularly among female sex
223 workers. This demographic exhibited a sharper rise and consistently higher seroprevalence than their male
224 counterparts. This age-related increase in HCV seropositivity is consistent with several other studies (9),
225 suggesting a cumulative risk of exposure and infection over time (9). The more pronounced increase among
226 female sex workers could be attributed to many factors, including prolonged exposure to high-risk
227 environments, compounded vulnerabilities, and potential barriers to accessing preventive services and
228 healthcare.

229 A noticeable relationship was observed between years of formal education and HCV seroprevalence among
230 the participating sex workers. Individuals with lower educational levels exhibited higher rates of HCV
231 seroprevalence, a markedly pronounced trend among female sex workers. This observed association
232 between education and HCV seroprevalence underscores the importance of addressing educational
233 disparities as a critical determinant of health. Tailored interventions to enhance health literacy and improved
234 access to education, are essential for reducing HCV seroprevalence and promoting health equity within this
235 population.

236 Our data indicates a notable difference in HCV seroprevalence in relation to marital status, particularly
237 among female sex workers. Married female sex workers manifested a considerably elevated seroprevalence
238 compared to their single counterparts. One plausible explanation for this occurrence could be that married
239 individuals may face complexities related to spousal relationships, familial responsibilities, and societal
240 expectations, potentially influencing their risk behaviors and access to healthcare. The dynamics of marital
241 relationships, including the potential for intimate partner violence and power imbalances, may limit the
242 autonomy of married female sex workers in negotiating safer practices and accessing preventive services.
243 Additionally, married female sex workers might experience dual sources of stigma and discrimination—
244 both as sex workers and as married women engaged in sex work. This compounded stigma can pose barriers
245 to healthcare access, hinder utilization of harm reduction services, and exacerbate vulnerabilities to
246 infections such as HCV (27, 28).

247 This study also examined the impact of various identified risk factors on HCV seroprevalence. The sharing
248 of blades emerged as a significant risk factor, with individuals engaging in this practice demonstrating
249 higher seropositivity. This observation aligns with the established knowledge that sharing sharp objects can
250 facilitate the transmission of blood-borne viruses like HCV, underscoring the importance of promoting safe
251 practices and awareness. Individuals with a surgical history, especially women, manifested alarmingly high
252 HCV seropositivity rates. This finding accentuates the critical role of medical procedures as potential
253 avenues for HCV transmission, necessitating stringent infection control measures and adherence to
254 sterilization protocols in healthcare settings. The exploration of other risk factors such as blood transfusion
255 history, history of injections, dental procedures, hospitalization, and drug abuse revealed analogous
256 patterns. These factors contributed to elevated HCV seropositivity rates, with the disparities being more
257 pronounced among women. The heightened vulnerability of women to these risk factors necessitates a
258 gender-sensitive approach to addressing HCV transmission.

259 One of the major limitations of our study is the smaller sample size of female participants. This
260 disproportion in representation between male and female participants could potentially introduce bias and

261 affect the robustness of the associations and patterns observed, particularly in relation to gender-specific
262 findings. This smaller female cohort size limits the generalizability of our findings to the broader population
263 of female sex workers in Pakistan and beyond. The gender-specific disparities and trends observed in our
264 study warrant further exploration through more extensive, more representative studies focusing on female
265 sex workers. Another potential limitation of our study is the self-reported data, which may be subject to
266 recall bias. Despite these limitations, our study contributes valuable insights into the HCV seroprevalence
267 among sex workers in Pakistan, laying the groundwork for future research and interventions tailored to
268 address the unique needs and vulnerabilities of this population. The insights garnered from this research
269 underscore the pressing need for concerted action and commitment to address the health disparities faced
270 by sex workers and to foster an environment conducive to their well-being and access to healthcare.

271 **Acknowledgments**
