52 **Abstract**

53 Bicuspid aortic valve (BAV), the most common congenital heart defect, is a major cause
54 of aortic valve disease requiring valve interventions and thoracic aortic aneurysms predisposing
55 to acute aortic dissections. The spectrum of BAV ranges from early onset valve and aortic
56 complications (EBAV) to sporadic late onset disease. Rare genomic copy number variants
57 (CNVs) have previously been implicated in the development of BAV and thoracic aortic
58 aneurysms. We determined the frequency and gene content of rare CNVs in EBAV probands (n
59 = 272) using genome-wide SNP microarray analysis and three complementary CNV detection
60 algorithms (cnvPartition, PennCNV, and QuantiSNP). Unselected control genotypes from the
61 Database of Genotypes and Phenotypes were analyzed using identical methods. We filtered the
62 data to select large genic CNVs that were detected by multiple algorithms. Findings were
63 replicated in cohorts with late onset sporadic disease (n = 5040). We identified 34 large and rare
64 (< 1:1000 in controls) CNVs in EBAV probands. The burden of CNVs intersecting with genes
65 known to cause BAV when mutated was increased in case-control analysis. CNVs intersecting
66 with *GATA4* and *DSCAM* were enriched in cases, recurrent in other datasets, and segregated with
67 disease in families. In total, we identified potentially pathogenic CNVs in 8% of EBAV cases,
68 implicating alterations of candidate genes at these loci in the pathogenesis of BAV.

69 **Author Summary**

70 Bicuspid aortic valve (BAV) is the most common form of congenital heart disease and
71 can lead to long-term complications such as aortic stenosis, aortic regurgitation, or thoracic
72 aortic aneurysms. Most BAV-related complications arise in late adulthood, but 10-15% of
73 individuals with BAV develop early onset complications before age 30. Copy number variants
74 (CNVs) are genomic structural variations that have been previously implicated in some types of
75 congenital heart disease, including BAV. Here we demonstrate that individuals with early onset
76 complications of BAV are enriched for specific rare CNVs compared to individuals with late-
77 onset BAV disease. We also describe novel CNVs involving *DSCAM*, a gene on chromosome 21
78 that has not previously been associated with the development of BAV. These results may lead to
79 improved risk stratification and targeted therapies for BAV patients.

80 **Introduction**

81 Copy number variants (CNVs) have been implicated as causes or modifiers of many
82 human diseases [1]. Specifically, large genomic CNVs are significantly enriched in cohorts with
83 developmental delay or congenital abnormalities, and the severity of phenotypes has been
84 correlated with the burden of rare CNVs [2]. These observations show that large, rare, *de novo*
85 CNVs are likely to be pathogenic and can exert clinically relevant effects on disease
86 pathogenesis [3-4].

87 Congenital heart disease (CHD) has a worldwide prevalence of 8.2 per 1000 live births
88 [5]. CNVs have been implicated in both syndromic and non-syndromic forms of CHD [6-10].
89 The pathogenicity and penetrance of CNVs was initially established for clinical syndromes such
90 as velocardiofacial syndrome, Turner syndrome, or Williams–Beuren syndrome, which involve
91 chromosomal or megabase scale duplications or deletions, but has since been expanded to
92 include additional CHD subtypes [10]. CNVs contribute to 10% of all CHD cases and up to 25%
93 of cases with extracardiac anomalies or other syndromic features [11]. The role of pathogenic
94 CNVs affecting genes that are known to cause CHD when mutated, such as *GATA4* and *TBX1*,
95 has been established [12]. Furthermore, population-level analysis has consistently demonstrated
96 an increased burden of CHD in carriers of CNVs at specific genomic hotspots compared to
97 controls, displaying the pathogenic potential of rare or *de novo* CNVs [12-14].

98 Bicuspid Aortic Valve (BAV) is the most common congenital heart malformation with a
99 population prevalence of 0.5 – 2% [15]. BAV predisposes to aortic valve stenosis and thoracic
100 aortic aneurysms and is associated with other left ventricular outflow tract lesions such as mitral
101 valve disease and coarctation [16]. The high heritability of BAV was demonstrated in first- and

102 second-degree relatives, who are more than ten times more likely to be diagnosed with BAV
103 compared to matched controls [17]. BAV can occur as an isolated congenital lesion or as part of
104 a clinical syndrome. For example, the prevalence of BAV is increased in Velocardiofacial,
105 Loey-Dietz, Kabuki, and Turner syndromes. Pathogenic variants of several genes are
106 implicated in familial non-syndromic BAV, which is typically inherited as an autosomal
107 dominant trait with reduced penetrance and variable expressivity. There is strong cumulative
108 evidence that *GATA4*, *GATA6*, *NOTCH1*, *ROBO4*, *SMAD4*, *MUC4*, and *SMAD6* each contribute
109 to a small percentage of non-syndromic BAV cases. Phenotypic expression of BAV disease
110 ranges from incidental discovery in late adulthood to neonatal or childhood onset of
111 complications. In comparison to patients with later disease onset, younger BAV cohorts tend to
112 present with syndromic features or complex congenital malformations that are more likely to
113 have a genetic cause, thereby increasing the power of association studies to discover clinically
114 relevant CNVs [18]. Recently, we identified recurrent rare CNVs that were enriched for cardiac
115 developmental genes in a young cohort with early-onset thoracic aortic aneurysms or acute aortic
116 dissections [19].

117 We hypothesize that large rare genomic CNVs contribute to early onset complications of
118 BAV. Consistent with previous observations, we predict that the burden and penetrance of rare
119 CNVs will be increased in individuals with early onset disease when compared to elderly
120 sporadic BAV cases and population controls. Identification of novel pathogenic CNVs can
121 provide new insights into the genetic complexity of BAV and may be useful for personalized risk
122 stratification or clinical guidance based on the specific recurrent CNV [20]. Therefore, we set out
123 to describe the burden and penetrance of rare CNVs in a young cohort with early onset
124 complications of BAV disease (EBAV).

125

126 **Materials and Methods**

127 The study protocol was approved by the Committee for the Protection of Human Subjects
128 at the University of Texas Health Science Center at Houston (HSC-MS-11-0185). After written
129 informed consent, we enrolled 272 probands of European ancestry with early onset BAV disease
130 (EBAV), which we defined as individuals with BAV who were under the age of 30 at the time of
131 first clinical event. Clinical events were defined as aortic replacement, aortic valve surgery,
132 aortic dissection, moderate or severe aortic stenosis or aortic regurgitation, large aneurysm ($Z >$
133 4.5), or intervention for BAV-related conditions. Those with hypoplastic left heart, known
134 genetic mutations, genetic syndromes, or complex congenital heart disease were excluded.
135 Affected and unaffected family members of probands were included in this cohort for a total of
136 544 individuals in 293 families (26 trios and 16 multiplex families). Samples were collected and
137 genotyped similar to our previous study [21]. For comparison, we analyzed a cohort of older
138 individuals of European ancestry with sporadic BAV disease selected from the International
139 BAV Consortium (Table 1) [22].

140

141

142

Table 1. Summary of Case Cohorts.

Cohort	Source	Sample Size	Array
EBAV	UTHealth Houston	544	Illumina GSA-24v1.0/2.0
BAVGWAS	International BAV Consortium	5040	Illumina GSA-24v3.0

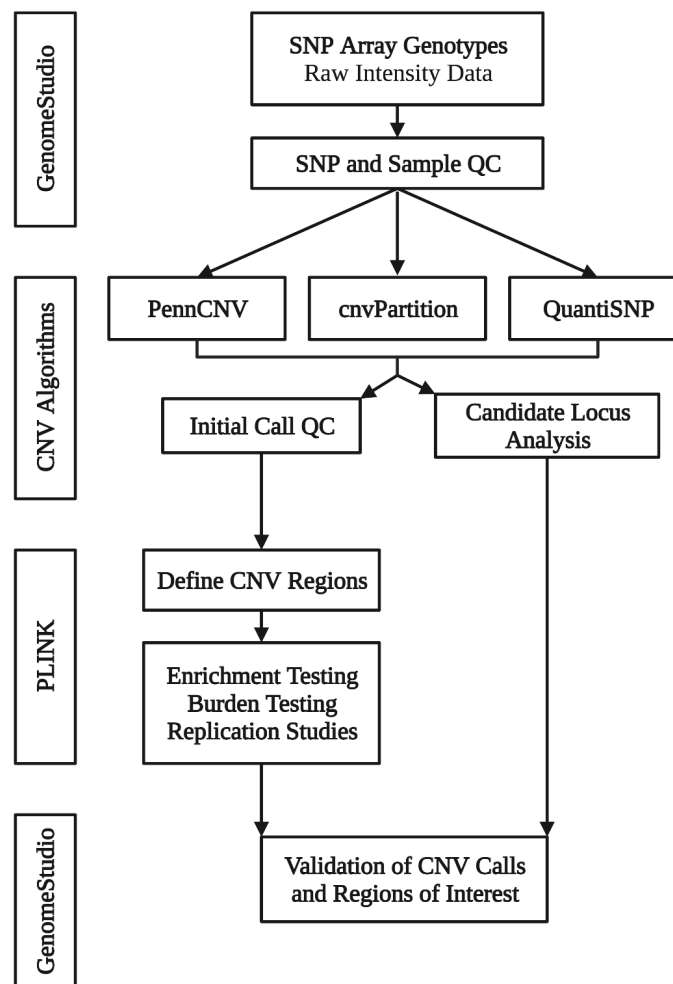

143 Cohort: name of case cohort; EBAV: family-based cohort selected for early onset complications of bicuspid aortic
144 valve (BAV); BAVGWAS: unrelated probands with sporadic BAV disease. Source: origin of genotypes; Array:
145 microarray used for genotyping.

146

147 Phenotypes were derived from record review with confirmation of image data whenever

148 possible [23-24]. The computational pipeline for CNV analysis of Illumina single nucleotide

149 polymorphism (SNP) array data included three independent CNV detection algorithms (Fig 1).

150

151 **Fig 1. Overview of Pipeline for CNV Identification and Validation.**

152 SNP, single nucleotide polymorphism. QC, Quality control. CNV, copy number variant. The software and
153 algorithms used for the analysis are provided in boxes to the left of the corresponding steps. Illumina raw signal
154 intensity data was trimmed and exported using GenomeStudio. The intensity data was then analyzed with three
155 different CNV calling algorithms (PennCNV [25], cnvPartition, and QuantiSNP [26]) to generate initial CNV calls
156 and sample-level statistics. Sample-level quality control analysis was performed using PennCNV. PLINK [27]
157 toolset was used to define CNV regions from initial CNV calls for subsequent burden testing, enrichment studies,
158 and replication studies. The initial CNV calls were individually screened for CNVs intersecting with candidate loci,
159 which we defined as genes implicated in bicuspid aortic valve disease and those discovered in our enrichment
160 studies. CNVs of interest were then validated in GenomeStudio.

161

162 GenomeStudio was used to exclude samples with indeterminate sex or more than 5%

163 missing genotypes, and single nucleotide polymorphisms (SNPs) with GenTrain = 0. Principal

164 component analysis was used to remove outliers that did not cluster with European ancestry.

165 Only SNPs common to all microarray platforms were included.

166 Three independent algorithms (PennCNV, cnvPartition, and QuantiSNP) were used to
167 generate CNV calls and sample-level quality statistics from SNP intensity data. PennCNV and
168 QuantiSNP were run on Unix clusters and cnvPartition data were exported from GenomeStudio.
169 The analysis was run using default configurations.

170 PennCNV was used to generate QC data and remove CNV calls that intersect with
171 polymorphic genomic regions. Samples that met any of the following criteria were excluded:
172 standard deviation of the LogR ratio (obtained from PennCNV) > 0.35 or number of CNVs > 2
173 standard deviations above the mean for each data set. CNV calls less than 20 kilobase pairs
174 and/or spanned by less than 6 SNP probes were excluded. The overlap function for rare CNVs in
175 PLINK was used to construct CNV regions (CNVRs) and adjacent regions were merged using
176 PennCNV.

177 LogR ratio (LRR) and B allele frequency (BAF) data at CNVRs and calls of interest were
178 visualized in GenomeStudio for validation. For segregation analysis, GenomeStudio was used to
179 determine the presence of CNVs in relatives.

180 A total of 22,014 unselected control Illumina Genotypes obtained from the Database of
181 Genotypes and Phenotypes were analyzed using identical methods (Table in S1Table). Cohorts
182 were paired as follows for case-control analysis based on the concordance of sample-level
183 quality control statistics (mean number of CNV calls and mean standard deviation of the LogR
184 Ratio): EBAV and WLS, BAVGWAS and HRS.

185 PLINK was used to catalog CNV calls and perform burden and enrichment studies. Case
186 - control burden tests were restricted to large (250 - 5000 kilobase pairs), rare (occurring in less
187 than 1 in 1000 samples; total of cases and controls), and validated CNV calls in EBAV probands.
188 Genome Reference Consortium Human Build 37 [28] was used for CNV annotation.

189 Results

190 Compared to BAVGWAS probands, EBAV probands were significantly younger at
 191 diagnosis, had more frequent co-existing congenital heart and vascular lesions, and underwent
 192 more frequent valve or aortic operations. A phenotype summary of the EBAV and BAVGWAS
 193 Cohorts is provided in Table 2.

195 **Table 2. Characteristics of EBAV and BAVGWAS Probands.**

	EBAV (n = 279)	BAVGWAS (n = 3141)
Female (%)	33	29
Age at diagnosis (years)	17 □ 13	52 □ 16
TAA (%)	20	37
Predominant AR (%)	12	40
Predominant AS (%)	20	37
Other Lesions (%)	53	1
Aortic Replacement (%)	27	16
Aortic Valve Surgery (%)	40	16

197 N: number of cases; □, standard deviation; TAA, thoracic aortic aneurysm; AR: aortic regurgitation; AS, aortic
 198 stenosis; Other Lesions, other congenital heart malformations (primarily coarctation or ventricular septal defect). We
 199 had phenotype information for 279 EBAV probands but did not have access to genotype information for all samples.

200
 201 CNV analysis is summarized in Table 3. The percentages of individuals with large and
 202 rare CNV regions were relatively consistent throughout datasets. The prevalence of large and
 203 rare CNVs, specifically large genomic deletions, was increased in EBAV cases compared to
 204 controls (Table S2).

205 **Table 3. Summary of CNV Calls for EBAV Cohort.**

	RATE	p^E	p^B	PROP	p^E	p^B	TOT	p^E	p^B	AVG	p^E	p^B
Large	0.51	1×10^{-7}	1	0.17	1	1	2648	1×10^{-7}	2.2×10^{-2}	690	1×10^{-7}	6×10^{-5}
Rare	0.36	0.79	1	0.21	1	1	426	6.1×10^{-4}	0.87	288	4.1×10^{-2}	0.6
Duplications	7.1×10^{-2}	0.96	1	6.8×10^{-2}	0.96	1	648	0.25	0.98	615	0.18	0.98
Deletions	0.11	1×10^{-7}	1	4.8×10^{-2}	1.9×10^{-2}	1	1477	1.1×10^{-3}	4.1×10^{-2}	608	0.23	1.7×10^{-2}

207 Large: CNV regions between 250 Kb and 5 Mb in length. Rare: occur in fewer than 1 in 1000 individuals; Rate:
 208 number of CNVs per individual; Prop: proportion of samples with one or more CNVs; TOT: total length of all
 209 CNVs in kilobases; AVG: mean CNV length. p^E , p -value for EBAV cohort in respective category. p^B , p -value for

210 BAVGWAS in respective category. Tests are 1-sided with 100,000 permutations. A subset of CNV calls from the
 211 EBAV and BAVGWAS datasets were validated by examining GenomeStudio plots. In total, 125/347 (36%) of
 212 EBAV and 289/600 (48%) of BAVGWAS CNVs were validated.
 213
 214 There were 34 large (>250 Kb), rare (<1:1000 in dbGAP controls) CNV regions that
 215 involved protein-coding genes in EBAV cases (Table S3). Seven of these genic CNVs were
 216 enriched in EBAV cases compared to WLS controls with a genome-wide adjusted empiric $P <$
 217 0.05. These CNVs included the genes *PCP4*, *DSCAM*, *MIR4760*, and *DSCAM-ASI* in 21q22 and
 218 *GATA4*, *C8orf49*, *NEIL2*, *FDFT1*, and *CTSB* in 8p23. Large duplications involving the
 219 Velocardiofacial (VCFS) region in 22q11.2 and 1q21.1 microduplications were also enriched in
 220 EBAV cases (Table S4). The overall burden of large, rare, genic CNVs was not different
 221 between EBAV cases and WLS controls. However, the burden of large, rare genic CNVs
 222 intersecting with genes known to cause BAV when mutated or implicated in syndromic BAV
 223 was significantly increased in EBAV cases (Table 4).

224 **Table 4. Burden Testing of Rare EBAV CNVs.**
 225

	<u>EBAV</u>		<u>WLS</u>		RR	P
	Calls	Rate	Calls	Rate		
Genic	28	0.8	1151	0.65	1.2	0.23
Deletions	11	3.8×10^{-2}	439	4.6×10^{-2}	0.81	0.78
BAV	3	1.0×10^{-2}	1	1.1×10^{-4}	97	1.1×10^{-3}
Total	34	-	1443	-	-	-

226 Calls: total number of CNVs that met the specified criteria. Rate: number of CNVs per individual; RR: relative risk;
 227 P: p-value; Genic; CNVs that intersect with genes; BAV: CNVs that intersect with genes that are known to cause
 228 bicuspid aortic valve (BAV) when mutated or implicated in syndromic BAV. Total: total number of large, rare
 229 CNVs or CNVRs. Tests are 2-sided using 100,000 permutations.
 230

231 We also scrutinized genomic regions that are implicated in CHD by careful analysis of
 232 data from individual CNV algorithms to detect subtle copy number alterations. We identified
 233 additional rare EBAV CNVs that intersect with CHD candidate genes *CELSR1*, *GJA5*, *RAF1*,
 234 *LTBP1*, *KIF1A*, *MYH11*, *MAPK3*, *TTN*, and the VCFS region in 22q11.2. We detected additional
 235 *GATA4* and *DSCAM* CNVs in multiplex families. These CNVs were enriched in EBAV cases
 236 compared to WLS controls (Table 5).

237

Table 5. CNVs Affecting Congenital Heart Disease Genes in EBAV Cohort.

Region	Genes	Case	Control	OR	95% CI
Chr22:46261909-51187440	<i>CELSR1</i>	1	1	33	2.1 to 530
Chr1:146326373-147340734	<i>GJA5</i>	1	2	17	1.5 to 183
Chr3:12599717-12803792	<i>RAF1</i>	1	2	17	1.5 to 183

238

Region: coordinates corresponding to the minimum overlap region of CNVs; Genes: cardio-developmental candidate genes in the region. Case: number of large and rare CNVs in EBAV cases that intersect with region of interest. Control: number of CNVs in WLS cohort that intersect with region of interest. OR: odds ratio; 95% CI, 95% confidence interval for respective odds ratio.

239

240

241

242

243

Next, we attempted to replicate our observations by identifying CNVs in the BAVGWAS

244

dataset that overlapped with rare EBAV CNVs. We found that large duplications involving

245

SOX7 and *GATA4* in 8p23 and the VCFS region in 22q11.2 were also significantly enriched in

246

BAVGWAS cases compared to HRS controls (Table 6, Table S6 and S7).

247

248

Table 6. CNVs Affecting Congenital Heart Disease Genes in BAVGWAS Cohort.

Region	Genes	Case	Control	OR	95% CI

249

Region: coordinates corresponding to the minimum overlap region of CNVs; Genes: cardio-developmental candidate genes in the region. Case: number of large and rare CNVs in BAVGWAS cases that intersect with region of interest. Control: number of CNVs in HRS cohort that intersect with region of interest. OR: odds ratio; 95% CI, 95% confidence interval for respective odds ratio.

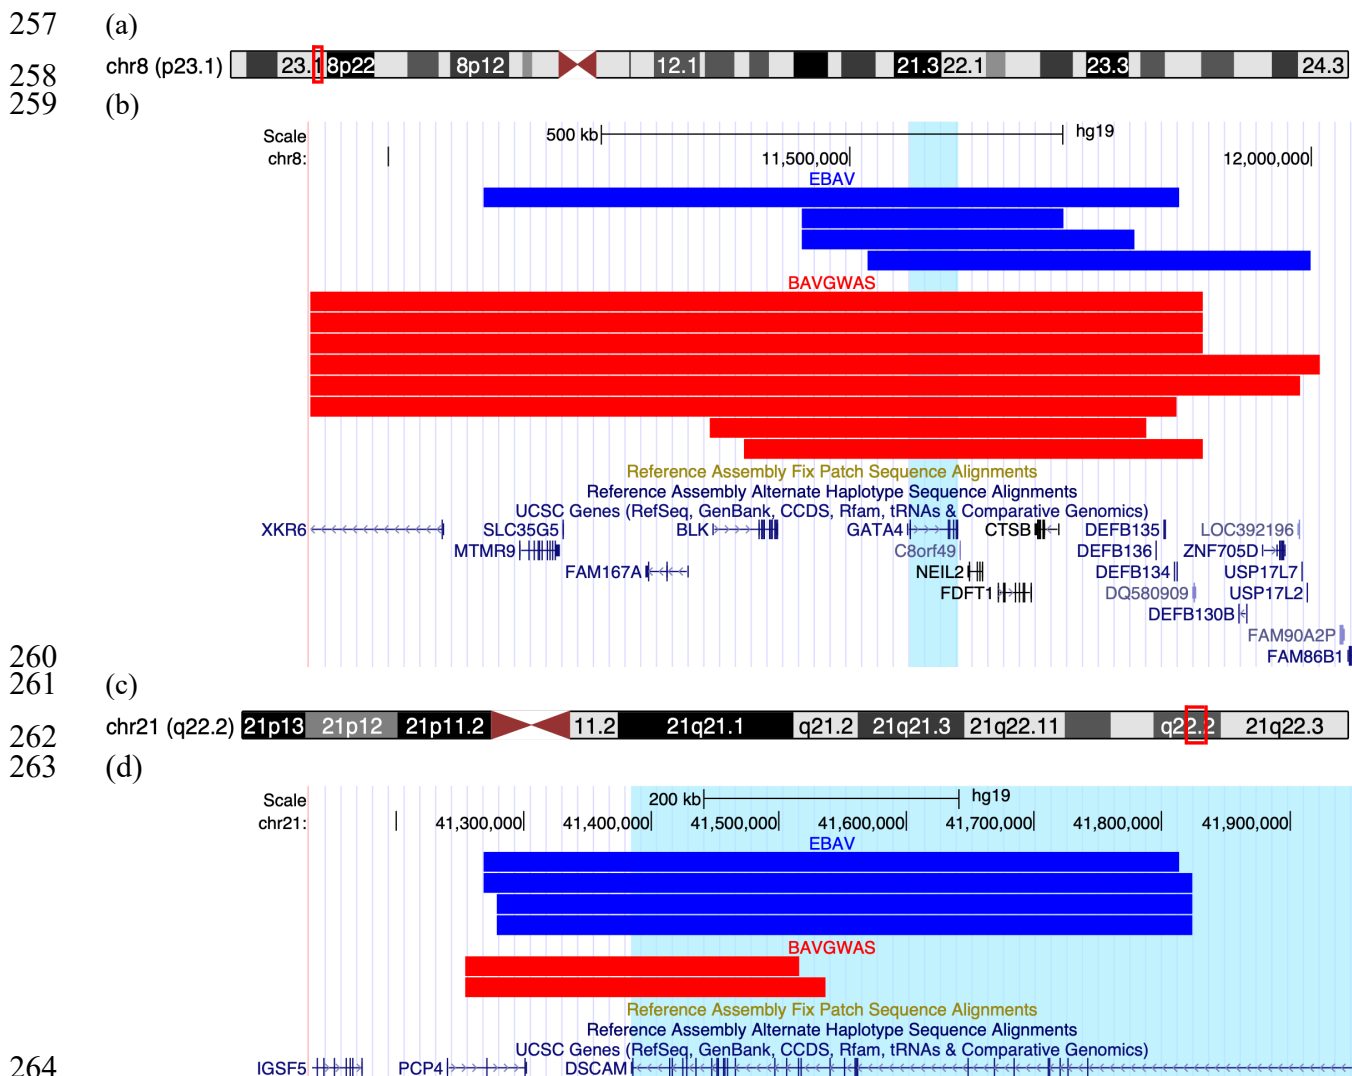

250

251

252

253

254 CNVs intersecting with *GATA4* and *DSCAM* significantly overlapped between EBAV
 255 and BAVGWAS datasets (Fig 2). On average, the *GATA4* CNVs were larger in the BAVGWAS
 256 dataset while the *DSCAM* CNVs were larger in the EBAV dataset.

264 **Fig 2. UCSC Genome Browser Plots of *GATA4* and *DSCAM* Variants.**

265 (a) Ideogram of Chromosome 8 with view of image in (b) outlined in red box. (b) Plot of *GATA4* variants. Each bar represents a copy number variant (CNV). CNVs from the EBAV cohort are in blue and CNVs from the BAVGWAS cohort are in red. The region spanned by *GATA4* has been highlighted in light blue. (c) Ideogram of Chromosome 21 with view of image in (d) outlined in red box. (d) Plot of *DSCAM* variants. EBAV CNVs are in blue and BAVGWAS CNVs are in red. The region spanned by *DSCAM* is highlighted in light blue. Figures constructed using the UCSC Genome Browser, <http://genome.ucsc.edu> [29].

274 We identified 7 additional CNV regions that are enriched in BAVGWAS cases but not in
 275 EBAV and are rare or absent in controls (Table S5). *NANOG* and *NIBPL* are essential for early

276 heart development, and mutation of *NIBPL* causes Cornelia-de Lange syndrome with a spectrum
277 of congenital heart malformations including BAV.

278 We also identified 21 very large genomic CNVs more than 5 Mb in length in the
279 BAVGWAS dataset. Analysis of GenomeStudio data showed that most of these were mosaic
280 loss of heterozygosity regions or duplications. Nine were large germline chromosome-scale
281 aberrations, including two cases of trisomy 21 (Table S8). We did not identify any large X
282 chromosome copy variants that may be consistent with Turner syndrome. There were no
283 megabase-scale copy number variants in the EBAV dataset.

284 Pedigree analysis showed that several CNVs involving *CELSR1*, *LTBP1*, *KIF1A*, *GATA4*,
285 and *DSCAM* segregate with BAV in EBAV families (Table S9). CNV carriers tended to present
286 due to moderate or severe aortic regurgitation requiring valvular surgery. One proband had aortic
287 coarctation. The youngest age at presentation was 13 years. There were no sex differences in
288 presentation between CNV carriers.

289

290 **Discussion**

291 We identified large, rare, and likely pathogenic CNVs in almost 10% of EBAV probands
292 that are enriched in genes that cause BAV when mutated. The percentage of EBAV cases with
293 likely pathogenic CNVs is similar to our previous observations in a cohort with early onset TAD
294 [30]. Enrichment of CNVs involving *GATA4* and *DSCAM* in EBAV cases replicated in two
295 additional BAV datasets and thousands of unselected control genotypes. This analysis provides
296 compelling evidence that rare CNVs collectively cause more BAV cases than any single mutated
297 gene.

298 GATA-Binding Protein 4 is a transcription factor that is required for cardiac and neuronal
299 differentiation during embryogenesis [31]. Mutations of *GATA4* and its homologs *GATA5* and
300 *GATA6* cause congenital heart lesions [32]. Mutations in the *GATA4* gene have been linked to a
301 range of congenital heart diseases in humans, such as cardiac septal defects, tetralogy of Fallot,
302 and patent ductus arteriosus [33]. Patients with BAV who have rare functional variants in the
303 *GATA* family exhibit varying degrees of aortopathy expression, including aortic aneurysm,
304 dissection, and/or aortic stenosis. Alonso-Montes et al. described 4 predicted deleterious *GATA4*
305 mutations in 122 non-syndromic BAV probands who did not have affected relatives [34]. Rare
306 *GATA4* deletions and putative loss of function mutations are also implicated in CHD with
307 distinctive features, underlining the importance of *GATA4* dosage to cardiac development [35-
308 36]. Glessner et al. discovered large *de novo* (~4Mb) duplications involving *GATA4* in CHD trios
309 with conotruncal defects or left ventricular outflow tract obstructive lesions [37]. Some
310 duplications were inherited from apparently unaffected parents. Zogopoulos and Yu described
311 similar genomic duplications in unaffected individuals and in unselected control genotypes [38-
312 39].

313 These observations are consistent with low-penetrance CHD in *GATA4* duplication
314 carriers. Similar to other complex and multifactorial disorders, CHD pathogenesis is likely
315 caused by the cumulative impact of multiple CNVs or mutations, each exerting small to
316 moderate effects to collectively disrupt cardiac development. For example, the frequency of
317 congenital heart lesions is increased in individuals with velocardiofacial syndrome who have
318 22q1.2 deletions and a common 12p13.31 duplication involving the *SLC2A3* gene. The *SLC2A3*
319 CNV likely functions as a modifier of the cardiac phenotype associated with 22q11 deletion
320 syndrome, exemplifying a “two-hit” model [40].

321 More than half of patients with Down syndrome have congenital heart malformations due
322 to the interaction of multiple dosage-sensitive CHD genes on chromosome 21 [41-43]. Down
323 syndrome cell adhesion molecule, previously shown to play a critical role in neurogenesis, has
324 also been implicated in the pathophysiology of CHD [44]. Analysis of rare segmental trisomies
325 of chromosome 21 suggested that duplication of *DSCAM* and the contiguous *COL6A1* and
326 *COL6A2* genes may cause septal abnormalities and other Down Syndrome-related CHD lesions,
327 including BAV. Overexpression of *DSCAM* and *COL6A2* causes cardiac malformations in mice
328 [45]. Our findings suggest that rare CNVs involving *DSCAM* may contribute to some non-
329 syndromic BAV cases.

330 Consistent with previous observations, *GATA4* and *DSCAM* CNVs segregated with
331 disease in multiple families, but are not fully penetrant and were detected in some unaffected
332 relatives. Intriguingly, large 22q11.2, *GATA4* and *DSCAM* CNVs were more highly enriched in
333 EBAV than in BAVGWAS cases, suggesting that these CNVs may drive early onset BAV
334 disease. These results are consistent with our observation that pathogenic CNVs involving
335 candidate BAV genes are also enriched in EBAV compared to BAVGWAS cases. Our data
336 suggests that pathogenic CNVs at these loci may predict accelerated disease onset or more severe
337 complications.

338 We also identified recurrent rare CNVs of specific dosage-sensitive regions that affect
339 cardiac developmental genes and are implicated in non-syndromic CHD. Recurrent 1q21.1 distal
340 deletions encompassing *GJA5*, the gene encoding Connexin-40, are associated with CHD lesions
341 including BAV. A study of 807 TOF cases showed significant enrichment of small duplications
342 spanning the *GJA5* gene, providing compelling evidence that it acted as the primary candidate
343 gene, supporting the association of *GJA5* and CHD [31]. Additionally, cardiac abnormalities

344 have been documented in mice with a targeted *GJA5* deletion, implying that haploinsufficiency
345 of *GJA5* might contribute to cardiac defects in individuals affected by 1q21.1 deletions [46].
346 *CELSRI*, a cadherin superfamily member, is mutated in families with BAV and hypoplastic left
347 heart syndrome [47]. *LTBP1* encodes an extracellular matrix protein that regulates TGF-beta and
348 fibrillin and has been implicated in congenital heart lesions [48]. *KIF1A*, encoding a kinesin
349 microtubule transporter, was implicated in a dominant multisystem syndromic disorder with
350 valvular and cardiac defects [49]. Mutation of *MYH11* causes familial thoracic aortic aneurysms
351 and dissections with an increased prevalence of BAV [50]. *TTN* mutations cause dilated
352 cardiomyopathy and are associated with other left-sided congenital lesions [51]. Mutations or
353 copy number changes involving these genes all cause a wide spectrum of penetrance and
354 phenotypic severity, consistent with sensitivity to genetic or clinical modifiers.

355 Our combinatorial analysis method eliminated many CNVs that were detected by single
356 algorithms or did not meet quality control benchmarks. Therefore, our analysis likely
357 underestimated the contribution of rare pathogenic CNVs to BAV. We also recognize that
358 cardiac development involves the complex interaction of many genes. We selectively validated
359 individual CNVs at loci of interest but may have underrepresented CNVs that had no *a priori*
360 relationship with CHD. The apparent penetrance of some CNVs may be less than expected due
361 to missing phenotypic information. The available clinical data was not sufficiently detailed to
362 permit genotype-phenotype correlations with specific CHD clinical features.

363 In conclusion, we identified large rare CNVs in a significant proportion of BAV cases,
364 including a subset of CNVs that may predict early onset complications of BAV disease. These
365 observations add to the evidence that rare CNVs may eventually have clinical utility for risk
366 stratification and personalized disease management.

Rare Deletions	59	181	285	394

551 **S2 Table. Comprehensive CNV Summary.** EBAV, EBAV Cohort including cases and unaffected family members.
552 BAVGWAS, BAVGWAS cohort. WLS, WLS cohort. HRS, HRS cohort. PennCNV, number of CNV calls detected
553 by PennCNV algorithm after quality control. cnvPartition, number of CNV calls detected by cnvPartition algorithm
554 after quality control. QuantiSNP, number of CNVs detected by QuantiSNP algorithm after quality control. Merged,
555 number of CNV regions after merging initial calls. Deletions, number of CNV regions that are deletions. >5 MB,
556 number of CNV regions that are larger than 5 megabases. Rare, number of large (> 250 kilobases and less than 5
557 megabases) CNV regions that occur in less than 1 in 1000 samples based on case-control cohort pairs (EBAV and
558 WLS; BAVGWAS and HRS). R. Del., number of large, rare deletions. All values reflect the total CNV calls and
559 regions prior to validation in GenomeStudio.
560

581 **S7 Table. BAVGWAS CNVs intersecting with Genes of Interest.** Gene/Region, Principal gene or region of
 582 interest intersected by CNV. Chr, chromosome on which each CNV is on. Start BP, start basepair of each CNV.
 583 Stop BP, stop basepair of each CNV. Type, denotes if a CNV was a duplication (DUP) or deletion (DEL) event.
 584
 585

Chr.	Start BP	Stop BP	Type	Description

586 **S8 Table. Large Genomic Events in BAVGWAS** Chr., Chromosome CNV on which CNV is located. Start BP,
 587 start base pair of CNV. Stop BP, stop base pair of CNV. Type, denotes if a CNV is a duplication (DUP) or deletion
 588 (DEL) event. Description, denotes if the CNV was a mosaic loss of heterozygosity (Mosaic LOH), loss of
 589 heterozygosity (LOH), mosaic (Mosaic), constitutional (constitutional), or trisomy 21 (Trisomy 21) event.
 590
 591

PROBAND	GENE	SEGREGATES?	WITH CNV	NO CNV	SEX
BAV064	<i>GATA4</i>	Yes	Father*, Paternal Grandfather*	Paternal Grandmother	Female
BAV475	<i>DSCAM</i>	Yes	Sister*	Father	Female
BAV787	<i>CELSR1</i>	Yes	None	Daughter	Female

BAV330	<i>KIF1A</i>	Yes	None	Father	Female
BAV478	<i>KIF1A</i>	Yes	None	Father	Male
BAV829	<i>LTBP1</i>	No	Son, Father	Mother, Brother	Female

592 **S9 Table. Pedigree Information for CNVs that Segregated with Disease.** Proband, identification number of
593 proband with CNV intersecting with gene of interest. Gene, gene of interest intersected by CNV. Segregates?,
594 indicates if the CNV segregated with disease. Family With CNV, family members of proband that were found to
595 have a CNV intersecting with the respective gene. Family Without CNV, family members of proband who were not
596 found to have a CNV intersecting with the respective gene. Family members are listed if their genotype was
597 available for the study. Sex, sex of the proband.
598 *Indicates family members who also have BAV.
