24 **Abstract**

25 Aims: Severity assessment for coarctation of the aorta (CoA) is challenging due to
26 concomitant morphological anomalies (complex CoA) and inaccurate Doppler-based indices.
27 Promising diagnostic performance has been reported for the continuous flow pressure gradient
28 (CFPG), but it has not been studied in complex CoA. Our objective was to characterize the effect
29 of complex CoA and associated hemodynamics on CFPG in a clinical cohort.

30 Methods and Results: Retrospective analysis identified discrete juxtaductal (n=25) and
31 complex CoA (n=43; transverse arch and/or isthmus hypoplasia) patients with arm-leg systolic
32 blood pressure gradients (BPG) within 24 hours of echocardiography for comparison to BPG by
33 conventional Doppler indices (simplified Bernoulli equation and modified forms correcting for
34 proximal kinetic energy and/or recovered pressure). Results were interpreted using the current
35 CoA guideline (BPG ≥ 20 mmHg) to compare diagnostic performance indicators including receiver
36 operating characteristic curves, sensitivity, specificity, and diagnostic accuracy, among others.
37 Echocardiography Z-scored aortic diameters were applied with computational stimulations from a
38 preclinical CoA model to understand aspects of the CFPG driving performance differences.

39 Diagnostic performance was substantially reduced from discrete to complex CoA for
40 conventional Doppler indices calculated from patient data, and by hypoplasia and/or long segment
41 stenosis in simulations. In contrast, diagnostic indicators for the CFPG only modestly dropped for
42 complex vs discrete CoA. Simulations revealed differences in performance due to inclusion of the
43 Doppler velocity index and diastolic pressure half-time in the CFPG calculation.

44 Conclusion: CFPG is less affected by aortic arch anomalies co-existing with CoA when
45 compared to conventional Doppler indices.

46 **Keywords**

47 Echocardiography, Antegrade diastolic flow, Diastolic runoff, Long Segment Coarctation,

48 Hypoplastic Aortic Arch, simulation, hypertension

49 **Abbreviations:**

AA	Ascending aorta
BP	Blood pressure
CFPG	Continuous flow pressure gradient
CoA	Coarctation of the aorta
DBP	Diastolic blood pressure
DVI	Doppler velocity index
MBE	Modified Bernoulli equation
PC-MRI	Phase contrast magnetic resonance image
ROM	Reduced order model
SBE	Simplified Bernoulli equation
SBE-RP	SBE modified for recovered pressure
SBP	Systolic blood pressure

50 **Introduction**

51 Coarctation of the aorta (CoA) is a constriction of the thoracic aorta and is one of the most
52 common congenital cardiovascular defects¹⁻³. While surgery is the optimal treatment in most
53 infants, 5-30% of treated patients develop re-coarctation requiring reintervention⁴ and > 90%
54 develop hypertension after 50 years of age⁵. Guidelines for intervention include a transcatheter
55 peak-to-peak CoA gradient (BPGpp) ≥ 20 mmHg that is often regarded as hemodynamically
56 significant⁶.

57 Despite allowing for direct measurement of the gradient, catheterization is an invasive
58 procedure with potentially unwanted risks⁷. BPGpp can also be estimated via cuffs placed on the
59 arms and legs. However, this is difficult in patients clinically due to children who may be upset,

60 crying or scared during measurement, and/or inappropriately sized cuffs⁸⁻¹⁰. Moreover, CoA
61 patients frequently have anomalies in their arterial anatomy that limit accurate determination of
62 BPGpp via BP cuffs. For example, the left subclavian artery is hypoplastic in many patients, and
63 branches distal to the coarctation in ~5% of patients¹¹. Non-invasive alternatives using continuous
64 wave Doppler are therefore commonly applied in echocardiography to estimate the BPGpp¹². This
65 often involves the systolic gradient estimated from peak Doppler velocity using the simplified
66 Bernoulli equation (SBE), or modified forms correcting for proximal kinetic energy (i.e., modified
67 Bernoulli equation: MBE) and/or recovered pressure (SBE-RP)¹³. These conventional Doppler
68 estimates are known to have poor agreement with catheterization¹⁴. Sources of disagreement
69 include local discrepancy in aortic dynamic distensibility, simplification of the Bernoulli equation,
70 and morphological variability, which can result in a substantial Doppler misclassification^{1,15}. This
71 misclassification is a critical barrier to assessing treatment modifications and translation since
72 interpretation of new thresholds is best done using tools with a high degree of accuracy and
73 diagnostic performance.

74 In contrast to tools exclusively focused on the systolic pressure gradient, we recently reported
75 on a novel Doppler-based tool that accounts for the diastolic pressure gradient, which we termed
76 the continuous flow pressure gradient (CFPG)¹⁵. Importantly, the CFPG was recently reported as
77 an independent predictor of hemodynamic severity in the setting of discrete CoA devoid of
78 complications found in complex CoA¹. The physiologic underpinnings of a pronounced diastolic
79 gradient can be explained by the prolonged recoil (i.e. capacitance) of the proximal aorta in
80 response to the flow-limiting stenosis that leads to antegrade diastolic run-off with a typical
81 sawtooth velocity decay¹. As mentioned above, CoA in patients often includes hypoplasia in one
82 or more arch segments presenting in concert with discrete CoA, or a long segment stenosis

83 resulting in additional sites of local blood flow acceleration (i.e., complex CoA). The objective of
84 the current study was to assess the diagnostic performance of the CFPG relative to conventional
85 Doppler indices in a pediatric cohort of discrete and complex CoA cases. We further set out to
86 determine the aspects of the CFPG that are driving differences in performance relative to
87 conventional Doppler-based indices, which was conducted using Z-scored aortic diameters from
88 the pediatric cohort in concert with representative computational hemodynamic simulations based
89 on a preclinical model of CoA.

90 **Methods**

91 Study design and patient involvement. To identify the most relevant research topics and
92 meaningful outcomes, the study was specially designed with the help of colleagues from the
93 Division of Pediatric Cardiothoracic Surgery at Children’s Wisconsin and Herma Heart Institute,
94 but no direct patient involvement was considered due to retrospective nature of the study design.
95 After exempt determination by the IRB Board of Children’s Wisconsin, analysis of 259 CoA
96 patients of either sex identified 25 cases with discrete juxtaductal CoA and 43 with complex CoA
97 (transverse arch and/or isthmus hypoplasia), as well as contemporaneous arm-leg systolic blood
98 pressure gradients via sphygmomanometry within 24 hours of echocardiography. Despite potential
99 limitations^{8–10}, sphygmomanometry was interpreted as a ground-truth for Doppler-based estimates
100 of the gradient from CoA since catheter-based BP gradients were not available. Patients with patent
101 ductus arteriosus, more than mild aortic valve insufficiency, other hemodynamically significant
102 congenital heart diseases, low cardiac output state, and abnormal ventricular systolic function on
103 echocardiography examination were excluded. Table 1 summarizes patient characteristics.

104 Echocardiographic measurements included conventional peak instantaneous pressure gradient
105 estimation by SBE, MBE and SBE-RP¹⁶. An estimate of the pressure gradient during diastole was

106 also calculated using diastolic flow continuation as characterized by the CFPG discussed in detail
107 elsewhere¹. All measurements were quantified from 2D and spectral Doppler images with early
108 diastolic velocity identified at the end of the T wave¹. Details related to echo quantification
109 methods are summarized in Supplemental Table 1.

110 Computational assessment of Doppler-derived index performance. Computational models
111 were constructed using a pre-clinical rabbit model mimicking CoA in patients^{17,18} since
112 measurements necessary to replicate physiology and aortic morphology beyond the coarctation
113 region were not available in the echocardiography data from pediatric patients retrospectively
114 studied. This approach allowed for understanding of hemodynamic factors impacting and/or
115 potentially limiting the utility of the Doppler-based indices studied, including CFPG. Arterial
116 segments were generated in SimVascular (simtk.org) using a control rabbit MRI dataset obtained
117 following Institutional Animal Care and Use Committee approval². The aortic diameter was then
118 quantified at various locations throughout the thoracic aorta. This step was important to identify
119 the normal population sized as baseline and realistically replicate discrete and complex CoA
120 characteristics by matching Z-scores from computational models to the clinical datasets.

121 Model construction involved centerline detection, segmentation using a semi-automated level
122 set method¹⁹, and lofting to create the blood flow domain. An in-house code was then developed
123 to generate local modifications with the guidance of a pediatric cardiovascular surgeon by
124 smoothly scaling aortic cross-sectional area according to shape functions²⁰ representing different
125 types of complex CoA including long-segment CoA, arch and isthmus hypoplasia (Supplemental
126 Figure 1). The resulting morphological properties replicated Z-scores observed at the equivalent
127 locations for each of the pediatric CoA patients²¹. A total of 68 computational aortas (25 with
128 discrete CoA and 43 with complex CoA) were created. The aorta models were then integrated with

129 arch branches (Supplemental Figure 2) for hemodynamic simulations with one inlet at the Sino-
130 tubular junction and outlets at each of the head and neck arteries.

131 One-dimensional computational reduced order models (ROM) were generated in SimVascular
132 (simvascular.github.io/) from the 3D CoA models²². The ROM approach was chosen for fast
133 determination of hemodynamic results used to calculate Doppler indices (Supplemental Table 1)
134 and automating the simulation process as compared to a semi-automated computationally intensive
135 process required for 3D simulations with additional spatiotemporal information not necessary for
136 the purpose of calculating Doppler-derived indices. A 3-element Windkessel model was
137 implemented at each outlet to realistically replicate downstream pressure-flow relationships²³
138 based on empirical measurements of pressure and flow from rabbits with discrete CoA.
139 Windkessel model parameters were then adjusted to represent hemodynamics for complex CoA
140 cases (see details in Supplemental Table 2). Data from discrete CoA rabbits with 42-96% area
141 obstruction were used to replicate clinical BPGpp¹⁸ and the influence of CoA on thickness and
142 stiffness after remodeling of the wall that were included in computational simulations (see
143 supplementary materials).

144 Statistical analysis. Hypoplasia proximal to the CoA was quantitatively characterized using
145 Z-score criteria²⁴. Arch and isthmus hypoplasia was considered significant for Z-scores < -3.0 (i.e.,
146 dimensions in the lowest 0.1% of the population). Pearson's correlation and linear regression were
147 used to characterize the relationship between Doppler-based estimates and simulated pressure
148 gradients. Adjusted R-squared values quantified the degree of scatter for each CoA severity and
149 morphology studied. Diagnostic performances were compared via receiver operative characteristic
150 (ROC) curves and relative to the current intervention guideline^{17,25} (i.e., BPGpp ≥ 20 mmHg). The
151 optimum cutoffs for Doppler indices were identified by maximizing the sum of sensitivity and

152 specificity, (i.e.; the Youden index²⁶) and the area under the ROC curves (AUC) was compared
153 using two-tailed student's t-test with 5 and 10% significance levels. Finally, sensitivity, specificity,
154 positive predictive values (PPV), negative predictive value (NPV), diagnostic odds ratio, and
155 diagnostic accuracy were also quantified as measures of diagnostic performance. Reliability of the
156 echo-based measurements used in calculating metrics including, SBE, MBE, SBE-RP, and indices
157 used in the calculation of the CFPG including the diastolic pressure half-time (dPHT) and Doppler
158 velocity index (DVI) was investigated using intraclass correlation coefficient (ICC) through SPSS
159 software. Two observers were trained to quantify echo-based indices on a random subgroup of
160 simulation and pediatric CoA patient datasets (n=10). Each metric was quantified in triplicate for
161 inter-observer variability with median values used for intra-observer variability analysis²⁷.

162 **Results**

163 Doppler quantification from the cohort of pediatric CoA patients showed decreases in
164 diagnostic performance moving from discrete to complex CoA morphologies, where correlation
165 to proximal acceleration was evident. For example, the diagnostic accuracy was 0.88, 0.87, 0.79
166 for SBE, MBE, and SBE-RP indices from discrete CoA cases. These values dropped to 0.69, 0.59,
167 and 0.59 for complex CoA cases, respectively. The diagnostic accuracy of CFPG was 0.96 for
168 discrete CoA morphologies, and modestly dropped to 0.88 for complex CoA data sets. A detailed
169 list of diagnostic performance indicators is provided in Table 2.

170 Similar patterns of reduced diagnostic performance were observed from the ROC analysis and
171 AUCs. Specifically, the AUC was 0.91, 0.91, and 0.90 for conventional Doppler indices (i.e., SBE,
172 MBE, and SBE-RP), which all significantly dropped to 0.80, 0.83, and 0.85, respectively (p-values
173 <0.01, Table 2). On the other hand, the AUC for CFPG remained high at 0.98-0.99 despite
174 additionally narrowing proximal to the coarctation for complex CoA cases (Table 2).

175 Reliability of the echo-based measurements used in calculating CFPG as quantified by ICC
176 index revealed ≤ 9.8 and 11.2% differences among inter and intra-observer measurements,
177 respectively. ICC index also confirmed good to excellent inter and intra-observer agreement in the
178 conventional Doppler indices quantified. The 95% confidence interval for ICC was [0.86,0.98] for
179 single subject variability and [0.91,0.99] on average, which is referred as excellent reliability
180 according to Cicchetti et al²⁸ and good according to Koo et al²⁷.

181 Before assessing the diagnostic performance of each Doppler-based index quantified using
182 echo data from the retrospective cohort of pediatric CoA patients via simulation, we first confirmed
183 morphological similarity via Z-scores. Z-scores at the proximal transverse arch, distal transverse
184 arch and aortic isthmus region were -3.22 ± 0.81 , -3.01 ± 0.72 , and -3.23 ± 1.50 in the cohort of
185 pediatric CoA patients, and corresponding values from computational models were -3.18 ± 1.18 ,
186 3.11 ± 0.52 , and 3.17 ± 1.68 , which were not significantly different (p-values > 0.1).

187 When compared to a discrete CoA, predictive values from conventional Doppler indices from
188 ROM simulations were substantially reduced by the addition of hypoplasia and/or long segment
189 stenosis in the arch. Specifically, the diagnostic accuracy was 0.63, 0.82, 0.80 for SBE, MBE, and
190 SBE-RP indices for simulations with discrete CoA configurations. These values dropped to 0.48,
191 0.80, and 0.73 for simulations of complex CoA models, respectively. In contrast, the diagnostic
192 accuracy of CFPG was 0.90 for simulations of discrete CoA morphologies, and only modestly
193 dropped to 0.83 for simulations of complex CoA. A detailed list of predictive values is provided
194 in Table 3.

195 A similar pattern of reduced diagnostic performance was observed in AUCs calculated from
196 ROC curves of Doppler indices determined by discrete CoA simulations (Figure 1, Table 3).
197 Specifically, the AUC was 0.90, 0.90, and 0.89 for conventional Doppler indices (i.e., SBE, MBE,

198 and SBE-RP) calculated from simulations, which significantly dropped to 0.83, 0.86, and 0.83,
199 respectively (p-values <0.01, Table 2). Moving from discrete to complex CoAs, ROC analysis
200 showed a pronounced shift towards non-diagnostic line (identity line, bottom left-to upper-right)
201 for simulations of conventional Doppler indices. On the other hand, ROC curves obtained by
202 CFPG calculated from simulations were relatively unchanged.

203 For simulations of discrete CoA, regression analysis resulted in $R^2 = 0.88$ for CFPG and 0.74-
204 0.76 for conventional Doppler indices (Figure 2). Simulations of complex CoAs revealed the
205 impact concomitant anomalies had on resulting flow patterns. For example, hemodynamic
206 alterations including proximal acceleration and increased jet velocity were observed resulting in a
207 higher degree of scatter (Figure 2). These factors decreased R^2 values for conventional Doppler
208 indices from simulations to 0.51-0.62, but to a lesser extent for CFPG calculated from simulations
209 (0.78), indicating that CFPG outperformed conventional Doppler indices for simulations of both
210 discrete and complex CoA.

211 **Discussion**

212 Suboptimal agreement with gold-standard catheterization represents a major limitation of
213 conventional Doppler-derived indices used for non-invasive CoA severity assessment^{14,29}.
214 Although diastolic continuation of flow and estimation of its associated pressure gradient using
215 the CFPG index previously showed strong correlation with measured values in a group of 25
216 discrete CoA patients¹, its performance relative to conventional Doppler-derived indices had not
217 been assessed in complex CoA morphologies. The main finding of the current study is that the
218 CFPG was more consistent than any of the other Doppler-derived indices studied in the setting of
219 complex CoA in a cohort of pediatric patients. It is also important to note that our results indicate

220 the CFPG better correlates with arm-leg pressure gradients than the other Doppler-derived indices
221 studied.

222 Performance differences among our novel CFPG method and conventional Doppler-derived
223 indices can be understood relative to the contribution of local stenoses beyond discrete CoA using
224 the simulations recounted above where physiologic boundary conditions were used to
225 computationally investigate the diagnostic performance of CFPG and three conventional Doppler
226 indices (SBE, MBE, and SBE-RP). Special care was taken to replicate morphological anomalies
227 seen in complex forms of pediatric CoA patients by implementing similar Z-scores in proximal
228 transverse arch, distal transverse arch, and aortic isthmus regions characterizing arch hypoplasia
229 relative to the normal population²⁴ (Table 1).

230 Differences in performance made clear by these simulations are rooted in the fact that the
231 CFPG includes several additional sub-indices described in Supplemental Table 1, namely the DVI
232 and dPHT, which consider the hemodynamic changes resulting in complex CoA cases. For
233 example, in complex CoA, the DVI (proximal to jet peak velocity ratio) can increase due to
234 proximal acceleration from a hypoplastic arch or isthmus (Figure 3, left). This leads to
235 underestimation of CoA (Figure 2, B and C), and leads to discrepancy between discrete and
236 complex CoA cases. However, the dPHT, which represents the time to half of the early diastolic
237 pressure (V_d to $\frac{\sqrt{2}}{2} V_d$ interval on the spectral doppler image, see Supplemental Table 1) accounts
238 for the prolonged recoil of the proximal aorta and associated antegrade diastolic flow. This leads
239 to consistent behavior of the dPHT in the setting of additional proximal stenoses in the form of a
240 hypoplastic arch and/or isthmus (Figure 3, right).

241 Consequently, although a mixed behavior is possible due to the DVI and dPHT having
242 opposite effects on the CFPG as indicated in Supplemental Figure 3, the CFPG is still relatively

243 insensitive to proximal acceleration in the clinical ranges of complex CoA studied. Specifically,
244 CFPG increases with dPHT making it more sensitive to additional proximal narrowing while, on
245 the other hand, it decreases with DVI as is also seen in MBE and SBE-RP. Therefore, collectively
246 the CFPG performance tends to be less affected by the proximal acceleration as suggested in the
247 AUCs shown in Figure 1 and values reported in Table 3.

248 Pronounced overestimation of the peak instantaneous pressure gradient commonly reported
249 in the literature for conventional Doppler-derived indices is further confirmed in the current work,
250 leading to superficial sensitivity of 1.00 for SBE compromising specificity. Conversely, sensitivity
251 values <0.14 will lead to a superficial diagnostic odds ratio (DOR) of infinity that positively
252 correlates with balanced sensitivity and specificity under normal circumstance. This imbalance
253 between sensitivity and specificity is particularly challenging in translational studies where
254 intervention guidelines (e.g., CoA gradient) are ideally identified using invasive high-fidelity
255 pressure measurements techniques such as catheterization, but results are being used in clinical
256 setting based on non-invasive estimations such as echocardiography. Hence, the improved
257 sensitivity-specificity balance observed in CFPG (Table 3) is promising evidence that this index
258 can be of more potential value translationally. Particularly, in the setting complex CoA
259 morphology, CFPG continues to deliver excellent balance between high sensitivity and specificity
260 that is also evident in DORs when compared to conventional Doppler indices. In clinical practice,
261 CFPG can be interpreted relative to the arm-leg cuff gradient identified using the current dataset.
262 Table 4 summarized CFPG cutoffs for a range of clinically important CoA gradients.

263 The current results should be interpreted relative to several limitations. For example, literature
264 suggests the arm-leg gradient may not be a strong predictor of invasive gradient in CoA patients^{1,30}.
265 Therefore, we expect the CFPG cutoffs obtained here may be different if sphygmomanometry data

266 are compared to gold-standard catheterization data, which were not available for the cohort of
267 pediatric CoA patients studied. Additionally, the cohort studied represented pediatric patients.
268 Hence, it remains to be determined if the relationships presented in Tables 2 and 4 are also
269 generalizable to older CoA patients. Complex morphologies were generated in computational
270 representations of rabbit aortas by replicating Z-scores seen clinically at the thoracic aorta for CoA
271 patients. This is in contrast to using measurements from the echo data within the CoA region of
272 pediatric patients that would need to be coupled with assumptions related to blood flow
273 distributions and dimensions of the ascending aorta and its branches. Considering these limitations,
274 clinical validation of CFPG in preventing postsurgical complications including hypertension has
275 yet to be studied in future work.

374 **List of Tables**

375 *Table 1- Characteristics for pediatric patients with discrete and complex CoA.*

CoA Morphology	Discrete		Complex*		p-values†
	N	%	N	%	
Sex					
Male	22	88	27	63	
Female	3	12	16	37	
Total	25		43		
Race and ethnicity	N	%	N	%	
White non-Hispanic	20	80	29	67	
White Hispanic	2	8	10	23	
Black or African American	3	12	4	9	
Pre-op echo characteristics	Mean	±SD	Mean	±SD	
Age [month]	29.5	9.10	30.9	15.6	0.73
Weight [kg]	13.1	3.85	13.3	4.00	0.91
Height [cm]	77.2	9.30	79.1	14.5	0.89
BSA [m ²]	0.77	0.21	0.73	0.12	0.66
SBP [mmHg]	99.0	6.30	103.0	8.10	0.49
DBP [mmHg]	63.6	4.08	57.2	11.8	0.17
Arm-leg systolic gradient	26.2	6.11	32.7	3.29	<0.001
Arch Diameter Z-scores	Mean	±SD	Mean	±SD	
Proximal Transverse Arch	-2.0	0.6	-3.2	0.8	0.03
Distal Transverse Arch	-2.3	0.7	-3.0	0.7	0.16
Aortic Isthmus	-2.3	0.7	-3.2	1.5	0.23
Min proximal Z-score	-2.5	0.5	-4.1	0.9	0.01

*CoA morphology was classified as Complex in presence of at least one additional narrowing at either the proximal transverse arch, distal transverse arch, or aortic isthmus. Classification was based on a Z-scores < -3 (i.e., the lowest 0.1 percentile of population according to Lopez et al²⁴)

†p-values quantified through two-tail student t-test

BSA: body surface area, DBP: diastolic blood pressure, SBP: Systolic blood pressure

376

377

378 *Table 2- Diagnostic performance of Doppler-derived indices in pediatric CoA patients at*
 379 *optimum ROC cutoffs.*

Index	Morphology	Diagnostic Performance					ROC measures			
		Sen.	Spec.	PPV	NPV	DOR	DA	Cutoff	AUC	p-value
SBE	Discrete	0.92	0.82	0.86	0.90	54.00	0.88	43.0	0.91	
	Complex	0.86	0.42	0.69	0.71	5.536	0.69	39.1	0.80	<0.01
MBE	Discrete	0.92	0.82	0.86	0.90	53.79	0.87	31.8	0.91	
	Complex	0.44	0.90	0.85	0.45	6.964	0.59	41.8	0.83	<0.01
SBE-RP	Discrete	0.76	0.82	0.83	0.75	15.00	0.79	32.5	0.90	
	Complex	0.57	0.69	0.82	0.31	2.925	0.59	24.9	0.85	<0.01
CFPG	Discrete	0.98	0.91	0.93	0.91	495.4	0.96	2.52	0.99	
	Complex	0.86	0.79	0.83	0.96	23.12	0.88	2.14	0.98	>0.10

AUC: area under the ROC curve, CFPG: continuous flow pressure gradient, DA: diagnostic accuracy, DOR: diagnostic odds ratio, MBE: modified Bernoulli equation, NPV: negative predictive value, PPV: positive predictive value, SBE: simplified Bernoulli equation, SBE-RP: simplified Bernoulli equation with recovered pressure term. The optimum cutoff value [mmHg] for Doppler indices was computed based on maximizing the sum of sensitivity and specificity, that is, the Youden index²⁸ to best represent the current intervention criterion of a trans-coarctation peak-to-peak gradient ≥ 20 mmHg. p-values represent statistical difference of AUC between complex and discrete CoA morphologies using two-tailed student t-test.

380

381

382 *Table 3- Diagnostic performance of Doppler-derived indices calculated at optimal ROC-derived*
 383 *cutoffs based on simulation results. Note the behavior from simulations is similar to data from*
 384 *pediatric CoA patients, with CFPG being a more consistent measure of diagnostic performance*
 385 *and ROC measures. This similarity allows for further analysis of those aspects of hemodynamics*
 386 *and performance impacting Doppler-based indices using the simulation results.*

Index	Morphology	Diagnostic Performance					ROC measures			
		Sen.	Spec.	PPV	NPV	DOR	DA	Cutoff	AUC	p-value
SBE	Discrete	1.00	0.14	0.60	1.00	Inf	0.63	44.8	0.90	<0.01
	Complex	1.00	0.12	0.44	1.00	Inf	0.48	40.9	0.83	
MBE	Discrete	0.85	0.81	0.73	0.90	25.29	0.82	39.9	0.90	<0.01
	Complex	0.84	0.78	0.67	0.88	32.02	0.80	48.7	0.86	
SBE-RP	Discrete	0.83	0.79	0.75	0.87	19.11	0.80	35.8	0.89	<0.01
	Complex	0.86	0.74	0.68	0.82	22.12	0.73	35.8	0.83	
CFPG	Discrete	0.92	0.83	0.84	0.91	60.09	0.90	3.01	0.98	>0.10
	Complex	0.88	0.81	0.85	0.88	38.02	0.83	2.65	0.98	

AUC: area under the ROC curve, CFPG: continuous flow pressure gradient, DA: diagnostic accuracy, DOR: diagnostic odds ratio, MBE: modified Bernoulli equation, NPV: negative predictive value, PPV: positive predictive value, SBE: simplified Bernoulli equation, SBE-RP: simplified Bernoulli equation with recovered pressure term. The optimum cutoff value [mmHg] for Doppler-derived indices was computed based on maximizing the sum of sensitivity and specificity (i.e. the Youden index²⁶) to best represent the current intervention criterion of a trans-coarctation peak-to-peak gradient ≥ 20 mmHg. p-values represent statistical difference of AUC between complex and discrete CoA morphologies using two-tailed student t-test.

387

388

389 *Table 4- CFPG cutoffs for a range of clinically important CoA gradients.*

CoA Gradient [mmHg]	Pediatric CoA Patient CFPG cutoff	
	Discrete	Complex
10	0.81	0.73
15	1.46	1.28
20**	2.52	2.14
25	4.20	3.45
30	6.90	5.49
35	11.22	8.63
40	18.14	13.47

CFPG: Continuous flow pressure gradient

390

391

392 **List of Figures**

393
 394 *Figure 1- Receiver operative characteristic (ROC) curves for Doppler-derived indices of CoA*
 395 *severity calculated from simulations. CoA were classified according to the current clinical*
 396 *threshold (i.e., peak-to-peak trans-coarctation gradient ≥ 20 mmHg). The optimal cutoff value for*
 397 *Doppler indices, as reported in Table 3, was computed based on maximizing the sum of*
 398 *sensitivity and specificity (i.e. the Youden index²⁶ indicated in dots for each ROC curve). Results*
 399 *are presented for Discrete (black-solid), and complex CoA morphologies (pink-dashed). CFPG:*
 400 *continuous flow pressure gradient, MBE: modified Bernoulli equation, RP: recovered pressure,*
 401 *SBE: simplified Bernoulli equation. Bar plots represent statistical difference of AUC between*
 402 *complex (pink) and discrete (black) CoA morphologies using student t-test with ** and ns*
 403 *indicating two-tail p-value < 0.01 and > 0.1 .*

404

405

406 *Figure 2- Comparison of Doppler-based indices from simulation results of discrete (black) and*
407 *complex (pink) CoA morphologies. Doppler-derived indices (vertical-axis) were quantified from*
408 *simulations using equations in Supplemental Table 1 including the (A) simplified Bernoulli*
409 *equation (SBE) and its modified versions, i.e., (B) MBE, and (C) SBE-RP, as well as the*
410 *continuous flow pressure gradient (CFPG). Adjusted R^2 in linear regression analysis (solid*
411 *lines) quantified degree of scatter resulting from each Doppler-derived index for discrete and*
412 *complex CoA morphologies. The carotid artery to descending aorta pressure gradient was also*
413 *quantified from simulation results to mimic the gold-standard CoA gradient from catheterization*
414 *(horizontal axis). Differences in performance for Doppler indices are rooted in the fact that the*
415 *CFPG includes several additional sub-indices described in Supplemental Table 1, namely the*
416 *DVI and dPHT, which consider the hemodynamic changes resulting in complex CoA cases*
417 *leading to a nonlinear correlation (Panel D and Supplemental Figure 3) more sensitive to*
418 *higher CoA severities.*

419
420 *Figure 3- DVI (left) and dPHT (right) ratios for discrete (black) and complex (pink) CoA*
421 *morphologies. No significant changes were observed in any of the indices between our cohort of*
422 *pediatric CoA patients and simulations matching Z-scores for aortic morphology (p-value >0.1).*
423 *There was a significant increase in DVI from discrete to complex CoA morphology in both our*
424 *cohort of pediatric CoA patients (p-values <0.01), and simulations helped to reveal this finding*
425 *is due to flow acceleration proximal to the CoA caused by hypoplastic arch, isthmus, or both. No*
426 *significant differences were observed in dPHT among morphologies (p-values >0.1). p-values*
427 *quantified using a two-tail student t-tests with 0.01 significance level.*
