Abstract

Background: Implementing new knowledge into clinical practice is a challenge, but nonetheless crucial to improve our healthcare system related to the management of musculoskeletal pain. This systematic review aimed to assess the effectiveness of implementation interventions within musculoskeletal healthcare.

Methods: We searched Medline, Embase, Cochrane Central Register of Controlled Trials, and Scopus. Any type of randomised controlled trials investigating implementation strategies or interventions in relation to musculoskeletal pain conditions were included. Risk of bias were assessed using the Cochrane Risk of Bias 2 tool. Data analysis was done using frameworks from Powell et al. 2015, and Waltz et al. 2015 and outcomes were identified by Thompson et al. 2022 or self-made outcome domains were established.

Results: The literature search yielded 14,265 original studies, of which 38 studies from 31 trials, with 13,203 participating healthcare professionals and 30,320 participating patients were included in the final synthesis. Nineteen studies had a high risk of bias, sixteen had a moderate risk of bias, and three had a low risk of bias. Twenty distinct implementation interventions were identified. A significant heterogeneity in the utilised outcome measurements was observed, thereby rendering a meta-analysis infeasible; consequently, all outcomes were classified into six outcome domains for healthcare professionals, seven for patients and one for cost-effectiveness.

Conclusions: Our findings suggest that some implementation interventions may have a tendency towards a statistically significant positive effect in favour of the intervention group on the outcome domain “Adherence to the implemented interventions” for healthcare professionals in the included studies. The remaining outcome domains yielded varying results; therefore, these findings should be interpreted with caution. Future high-quality trials with clear reporting and rationale of implementation strategies and interventions utilising standardised nomenclature are needed to further advance our understanding of this area.

Keywords: Implementation strategy, Implementation intervention, Musculoskeletal pain, Systematic Review

Background

Musculoskeletal pain conditions are a significant burden on societies and healthcare systems worldwide (1,2). In 2019, musculoskeletal conditions affected 1.71 billion people worldwide, and the prevalence is expected to rise owing to aging populations and changing lifestyles (1,3). In addition, the economic and societal impact is severe due to lost productivity, including sick days, lost labour, early retirement and increased healthcare utilisation, and healthcare systems globally spend a significant proportion of their assigned resources on treating musculoskeletal conditions (4–6). Currently, most healthcare services in the western world face a substantial challenge: unnecessary testing and treatment seem to be abundant and lead to wasted economic resources for both patients and the healthcare system (7–12). As patients with musculoskeletal conditions often seek care from healthcare professionals (HCPs), most countries’ health authorities have issued a series of evidence-based guidelines of best practice for the most common conditions; however, adherence to these guidelines seems to be poor (13). In addition, several global and local initiatives have been launched in an effort to reduce unnecessary testing and treatment (14–17). The literature acknowledges the difficulty in implementing evidence-based guidelines (18). Some studies have demonstrated a significant delay between the development of new knowledge and its uptake in clinical practice (19,20). Therefore, the study of implementation science is crucial for developing effective and efficient implementation strategies to ensure that HCPs across various sectors incorporate this knowledge into musculoskeletal healthcare. An implementation strategy consists of a bundle of two or more implementation interventions, which are defined as “a method or technique designed to enhance adoption of a clinical intervention” (21). Several models and

frameworks for implementation have been suggested in the literature that can guide the selection of the most appropriate implementation strategy depending on the task at hand (22,23). However, it remains unclear which implementation strategies and interventions are the most effective in various musculoskeletal healthcare settings. Therefore, the aim of this systematic review was to assess which implementation interventions are effective within musculoskeletal healthcare.

Methods

Protocol and Registration

This study protocol were preregistered in Open Science Framework (DOI: [10.17605/OSF.IO/SRMP2](https://doi.org/10.17605/OSF.IO/SRMP2)). The reporting of the study followed the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) guidelines See the completed PRISMA checklist in *Additional file 1*.

Deviation from Protocol and Preregistration

Several deviations from the protocol occurred due to various reasons. Firstly, our pre-registration stated that the extracted outcomes would be divided into primary- and secondary outcomes, however, for the sake of simplicity, we categorised outcomes into HCP-related, patient-related, and economic-related outcomes and only extracted primary outcomes for each included study. Secondly, we stated that we intended to have two authors extract data independently, but to ensure feasibility, timeliness, and rigour, one author extracted data which were validated by another author.

Study Inclusion and Exclusion Criteria

Only randomised control trials (RCTs) were included for this study. Studies were included if they were randomised by individuals, clusters or used a stepped-wedge design. Furthermore, all studies

needed to be published in English, include at least one implementation strategy or intervention in relation to musculoskeletal healthcare (defined as a method or technique used to enhance the adoption, implementation, and sustainability of a clinical program or practice), include either authorised healthcare practitioners or adults aged ≥ 18 years diagnosed with a musculoskeletal pain condition (21). Studies describing an implementation strategy or intervention but only evaluating the different treatments and not different implementation strategies or interventions of the same treatment were excluded. Studies that were non-experimental, involved animals, patients with serious pathology or patient populations below the age of 18 were excluded. No limitation on publication date and time periods were applied.

Searches

The databases Medline via PubMed, EMBASE, Cochrane Central Register of Controlled Trials (CENTRAL), and Scopus were searched on the 22.02.2023 using the terms, "musculoskeletal Conditions", "Implementation Strategies", and "RCT". Furthermore, relevant search terms were identified through manual searches, and standardised keywords and Medical Subject Headings (MeSH) were applied to ensure specificity for each individual database. An experienced librarian (JFJ) assisted in building the comprehensive literature search. Additionally, to ensure comprehensive coverage of the literature, the reference lists of eligible studies were reviewed to identify any potentially eligible studies using a forward citation search. See the full literature search in *Additional file 2*.

Study Selection

Covidence Software (Covidence Systematic Review Software, Veritas Health Innovation, Melbourne, Australia) was used in the selection process, and duplicates were removed from the

initial search results. The selection process, which was performed by four independent authors (PBH, MSN, MEB and KDL), was divided into two phases. The first phase involved screening of titles and abstracts, and the second phase involved full-text screening. The screening was carried out by two independent reviewing authors for each study- in both phases (PBH, MSN, MEB or KDL). In case of conflicts between the independent authors or insufficient information from the title and abstract, the study was moved to full-text screening. In the second phase, the full text was examined by two authors to determine whether it met the eligibility criteria (PBH, MSN or MEB) (PBH, MSN or MEB). Conflicts in the full-text phase were resolved through a consensus discussion process involving three authors (PBH, MSN and MEB) and senior authors (MSR and KDL).

Data Extraction

A purpose-built Excel sheet was used for data extraction. We collected and extracted data on study characteristics (study title, author, year, study design, country, clinical setting, sample size of HCPs and patients, and implementation strategy for intervention and control groups), and only findings of primary outcomes for HCPs, patients, and cost-effectiveness for each individual study. Three reviewers (PBH, MSN and MEB) performed data extraction from the included studies. For each study, there was a primary data extractor and one who checked for accuracy and completeness.

Study Quality Assessment

To assess the risk of bias in individual studies, the Cochrane Risk of Bias tool 2 (A revised Cochrane risk of bias tool for randomised trials (RoB 2) was used (24). If the included studies were cluster randomised controlled trials, the RoB 2 tool for cluster-randomised trials was applied. Both tools assessed the risk of bias across five different domains, where RoB 2 for cluster-randomised trials divided the first domain into parts A and B. Each study was classified based on RoB 2 into

three categories: high risk of bias, some concerns of risk of bias, or low risk of bias. Two independent reviewers (PBH, MSN or MEB) assessed the risk of bias, and conflicts were resolved through a consensus discussion process involving three authors (PBH, MSN and MEB) and senior authors (MSR and KDL).

Data Synthesis and Presentation

Findings were presented descriptively. Two authors (PBH, MSN, MEB) independently categorised and mapped the implementation strategies in each study into implementation interventions and clusters using the nomenclature provided by Powell et al. 2015 and Waltz et al. 2015 (25,26). Discrepancies were resolved through a consensus discussion process involving three authors (PBH, MSN and MEB) while senior authors (MSR and KDL) were available if consensus could not be reached. The primary outcomes from each included study were condensed into a set of outcome domains through discussions. Three authors (PBH, MSN and MEB) mapped patient outcome domains using a core outcome set by Thompson et al. 2022 (27). Three authors (PBH, MSN and MEB) pragmatically mapped and formulated HCP outcome domains and outcomes of cost-effectiveness without using a core outcome set because none existed. However, inspiration for the HCP outcome domains was gathered from Proctor et al. 2011 (28). The process of creating the HCP outcome domains and the definitions of all outcome domains are presented in *Additional file 3*. The findings of the primary outcomes in each study were used to create a tabular view of the effectiveness of different implementation interventions. All results concerning the primary outcomes in the included studies were divided into four categories of significance using probability values (p-values) (29,30). These four categories were defined as:

1. “Statistically significant positive effect in favour of intervention group” (S).
2. “No statistically significant positive effect in favour of intervention group” (NS).

3. “Mixed findings of statistically significant effect” (MS) for studies showing both S and NS classified within the same outcome domain.
4. “Unknown statistically significant effect” (US) for those who did not produce a p-value and showcased the results as descriptive statistics.

A statistically significant positive effect in favour of the intervention group was defined as a p-value of ≤ 0.05 . However, due to some studies not presenting p-values, we interpreted odds ratios with 95% confidence intervals not including “1” and cost-effectiveness with 95% confidence intervals not including “0” as statistically significant.

Results

Study Selection

The systematic literature search resulted in 14,255 original results. Ten studies, not captured by the systematic literature search but found through manual searches, were also included (31–40). 14,196 studies were excluded during screening of titles and abstracts and 31 studies were excluded during screening of full texts. After screening 38 studies from 31 trials remained for final inclusion (31–68) (See **Figure 1** for PRISMA Flow chart).

INSERT FIGURE 1 HERE - LEGEND: *The Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) Flowchart illustrating the screening and selection process including reasons for exclusion.*

Study Characteristics

The 38 included studies were published between 2001 and 2022. Of the 38 studies, six used a standard RCT design and 32 used a cluster RCT design, of which three utilised a stepped-wedge design. A full description of study characteristics including author, year, study design, sample size, clinical setting, country of origin, implementation strategies and interventions, primary outcomes and findings of the 38 included studies are summarised in *Table 1. Additional file 4* presents *Table 1* in further detail including categorization of implementation interventions. Twenty-nine studies focused on measuring outcomes related to HCPs, ten studies on outcomes related to patients, and four studies on outcomes related to cost-effectiveness. A total of 13,203 HCPs were recruited in the 38 included studies. Twenty-one studies recruited general practitioners or physicians including family physicians, emergency physicians or primary care physicians (n=9558), 19 studies recruited physiotherapists (n=2194), one study involved osteopaths (n=598), three studies involved chiropractors (n=584), three studies involved nurses, rheumatologists, and spinal surgeons, respectively, but failed to report on the number of participants. Overall, five studies failed to report the number of recruited HCPs. A total of 30,320 patients were recruited in the 38 included studies. Thirty studies involved patients with LBP (n=26,774), four studies involved patients with neck pain (n=1460), five and four studies involved patients with knee pain and patients with hip pain, respectively, but failed to report the number of participants. Overall, 11 studies did not include patients or failed to report the number of recruited patients. Twelve of the included studies used data from the same RCT as other studies (35,41–44,52,54–56,59,65,66).

INSERT TABLE 1 HERE - LEGEND: *Study Characteristics of all Included Studies*

Effect of Implementation Interventions

The categorization and mapping of the included studies, by implementation clusters and interventions combined with the outcome domains of primary outcomes for each implementation intervention, are presented in *Figure 2. Additional file 5* presents the synthesis of the categorised included studies into implementation interventions and outcome domains with the corresponding references.

The most common intervention utilised in the literature is "Distribute educational materials" and 30 of the included studies utilised this implementation intervention. Among them, six out of ten studies assessing the outcome domain "Adherence to implemented intervention" found a statistically significant positive effect in favour of the intervention group. For the outcome domains "Referral to imaging", "Referral to secondary care" and "Function" four out of ten studies, two out of six studies and one out of six studies found a statistically significant positive effect in favour of the intervention group, respectively.

Twenty-nine of the included studies utilised the implementation intervention "Conduct educational meetings". Among them, seven out of nine studies assessing the outcome domain "Adherence to implemented intervention" found a statistically significant positive effect in favour of the intervention group. For the outcome domains "Uptake of knowledge", and "Function", three out of ten studies and two out of seven studies found a statistically significant positive effect in favour of the intervention group, respectively.

Twenty-two of the included studies utilised the implementation intervention "Conduct local consensus discussion". Among them, five out of seven studies assessing the outcome domain "Adherence to implemented intervention" found a statistically significant positive effect in favour

of the intervention group. For the outcome domain "Uptake of knowledge" two out of eight studies found a statistically significant positive effect in favour of the intervention group.

Twenty-one of the included studies utilised, the implementation intervention "Make training dynamic". Among them, five out of seven studies assessing the outcome domain "Adherence to implemented intervention" found a statistically significant positive effect in favour of the intervention group. For the outcome domains "Uptake of knowledge", and "Function", three out of ten studies and one out of five studies found a statistically significant positive effect in favour of the intervention group, respectively.

Eighteen of the included studies utilised the implementation intervention "Conduct ongoing training". Among these, two out of eight studies measuring the outcome domain "Uptake of knowledge" and two out of five studies measuring the outcome domain "Function" found a statistically significant positive effect in favour of the intervention group.

Sixteen of the included studies utilised the implementation intervention "Conduct educational outreach visits". Two out of six studies measuring the outcome domain "Function" found a statistically significant positive effect in favour of the intervention group.

Four studies examined the cost-effectiveness. These studies produced inconsistent findings and employed varying outcome measures of effectiveness.

Lastly, across all outcome domains, several different outcome measures were utilised in the included studies See *Additional file 4* for the specific outcome measures utilised.

INSERT FIGURE 2 HERE - LEGEND: *Mapping Implementation Interventions for Musculoskeletal Healthcare*

Study Quality Assessment

All 38 studies were assessed for risk of bias using RoB 2. Three studies were judged to have a low risk of bias, 16 studies to have some concerns about risk of bias, and 19 studies to have a high risk of bias. The overall results of the risk of bias assessment using RoB 2 is presented in *Table 1*. *Additional file 6* illustrates a detailed version of the results of the risk of bias assessment for each RoB 2 domain.

Discussion

Summary of findings

This systematic review investigated the effectiveness of different implementation interventions in musculoskeletal healthcare and included 38 studies. Our synthesis of the findings from the included studies indicates that implementation interventions have diverse effects on HCP outcomes. Regarding studies measuring patient outcomes, implementation interventions may not lead to significant improvements. Conflicting findings were observed concerning cost-effectiveness outcomes, and we were unable to draw clear conclusions in this regard. Studies measuring the outcome domain “Adherence to the implemented intervention” may indicate a statistically significant positive effect in favour of the intervention group across most implementation interventions.

The most common implementation interventions utilised in the literature were “Distribute educational materials”, “Conduct educational meetings”, “Conduct local consensus discussion” and “Make training dynamic”. The majority of the studies utilising these interventions and measuring the outcome “Adherence to implemented intervention” found a statistically significant positive effect in favour of the intervention group.

Assessment of risk of bias using the RoB 2 tool revealed that most studies had either some concerns or a high risk of bias.

Explanation of findings

The conflicting findings on HCP outcomes might be explained by significant methodological concerns such as the possibility of selection bias. It is likely that the HCPs who agreed to participate in the studies had extensive experience, continued education and were more inclined to be adherent with high quality of treatment and high baseline measurements, leaving less potential for improvement (31,32,38,39,48,49,51,52,59,61,63,66,67). Furthermore, the participating HCPs may have been more motivated with a positive attitude towards the implemented intervention implying a readiness to change (40,43,48–50,58,59). In addition to this, it is also possible that simply participating in a study and being observed may have resulted in greater adherence to the implemented intervention (48,58,59). These factors may have contributed to an increased effect of the implemented intervention in both the intervention and control groups across studies, thus obscuring the possible effect. The conflicting findings on patient outcomes and cost-effectiveness might equally be explained by the potential influence of selection bias, where HCPs in the control group possessed significant experience and interest in management of musculoskeletal conditions. This could potentially result in a higher likelihood of adhering to the implemented intervention with a high quality of treatment, leaving less potential for demonstrating a statistically significant difference between patient groups (32,35,40,44). Additionally, the absence of a significant effect may be attributed to unaccounted mediating confounders among patients, such as fear-avoidance and anxiety, as well as issues related to inclusion and substantial loss to follow-up (33,41,64). It is reasonable to suggest that the lack of effect on patient outcomes might, in part, contribute to the absence of cost-effectiveness (29,69). Only 20 of the 38 included studies provided a rationale for

selecting the specific implementation strategy and interventions they examined (31–33,35–37,43,44,46,47,49–53,56,58,60,65,66). Despite providing a rationale for the choice of an implementation strategy and interventions, in many cases the rationale remained vague and not thoroughly reported. The absence of or vague rationales could potentially explain the conflicting findings observed in this review. Some literature illustrates the importance of providing a clear and well-thought rationale including exploring barriers and facilitators for changing practice behaviour, as this can affect the success of the implementation (26,70–73). In addition, the existing literature emphasises the importance of utilising implementation interventions targeting relevant mechanisms of change to address identified barriers and facilitators for behaviour change when selecting and tailoring of implementation strategies and interventions(74,75). Failing to tailor the implementation strategies and interventions towards relevant barriers and facilitators for behaviour change could result in random findings with small to moderate effects as observed in this review. Due to this it is recommendable that future research thoroughly describes the implementation strategy and provide an underlying rationale in detail.

Agreements and Disagreements with Existing Literature

All single implementation interventions in this review showed various effects across all outcome domains, yet there seems to be a tendency towards a statistically significant effect in favour of the intervention group on the HCP outcome domain “Adherence to implemented intervention” for several implementation interventions. These findings align with existing literature within musculoskeletal healthcare indicating no single implementation intervention consistently outperform others across outcome domains (29,76–80). Similar findings are seen when looking at implementation interventions in a wider perspective within healthcare with implementation interventions such as providing audits and feedback, using local opinion leaders, using educational

materials and using educational meetings and workshops potentially contributing to positive outcomes related to HCPs but not patients (81–84). This means that it might be recommendable to consider the following implementation interventions “Conduct local consensus discussions”, “Make training dynamic”, “Distribute educational materials“, “Conduct educational meetings”, “Audit and feedback” and “Using local opinion leaders” when creating an implementation strategy aiming at HCP behaviour change (81–84). Our results indicate a lack of positive outcomes in favour of the intervention group for patient outcome domains, which is consistent with findings from other reviews in musculoskeletal healthcare and broader healthcare implementation studies (29,67,76–78,80–85). This suggests that we currently lack effective implementation interventions to yield better patient outcomes. In addition, it could be speculated that the quality and efficacy of some of the implemented interventions and utilised measurements might be inadequate for changing and measuring patient outcomes. Our results concerning cost-effectiveness from four studies showed conflicting findings across implementation interventions. However, findings from existing literature show similar conflicting results, which could be explained by heterogeneous studies with different types of implementation interventions and outcomes (69,81). Due to this we, as well as other research, suggest that adding a cost-effectiveness analysis to a study concerning implementation interventions to demonstrate feasibility and contribute to more evidence regarding cost-effectiveness (67).

Strength and Limitations

To our knowledge, this systematic review is the largest focusing on RCTs concerning implementation interventions in musculoskeletal healthcare, which is a considerable strength of this systematic review. Furthermore, the wide search strategy, which was developed in collaboration with an experienced librarian, yielded a much more comprehensive result than previous reviews on

the subject (29,67,76–78,80). Despite this, we identified further 10 studies by manually searching, which showcase the substantial heterogeneity in both methodology and nomenclature in the field of implementation science. Our study has several limitations; we utilised the definition and nomenclature of implementation interventions as described in Powell et al. 2015 (25). However, a substantial amount of the definitions remain vague, and as such the classification is based on an individual assessment. This is equally in part to the poor description of implementation strategies and interventions in most of the included studies, and as such we were forced to make assumptions and individual interpretations in many cases. These challenges will undeniably result in discrepancies between reviews, as for instance in Goorts et al. 2021 there is a discordance in identifying and classifying interventions compared to ours (29). Therefore, future research should utilise standardised methodology and nomenclature to ensure consensus.

To our knowledge, this is the first review seeking to clarify which implementation interventions are effective within musculoskeletal healthcare. To do that, we decided to dissect the included studies' implementation strategies into implementation interventions and classify these. However, in most studies, more than one implementation intervention could be identified, and it could be speculated that the effect sizes are due to multiple specific implementation interventions being used in conjunction with each other, which is a factor this review has not accounted for. Substantial heterogeneity was observed in the included studies. For example, when measuring adherence to the implemented intervention or patient functioning, there was hardly ever the same outcome measure appearing twice. To overcome this heterogeneity all primary outcomes were condensed into three sets of outcome domains. For patient outcomes we attempted to utilise a core outcome set for exercise and physical activity interventions for musculoskeletal disorders (27). However, not all patient outcomes were a core outcome according to Thompson et al. 2022, despite this, we chose to include these as domains regardless. This core outcome set was not in complete agreement with this

study as we were not investigating treatments specifically consisting of exercise and physical activity, but to our knowledge nothing better existed. A limitation of this study was that to our knowledge no core outcome sets exist for HCP outcomes and cost-effectiveness. Therefore, to invent our own outcome domains will not be as generalizable to other studies as utilising an existing core outcome set. However, this domainisation of outcomes had the advantages that it made it possible to homogenise and synthesise the various heterogeneous outcomes of the included studies. Furthermore, we highlighted some implementation interventions to be more effective than others. These findings were based solely on observations of our synthesis, and as such it is important to note that these findings are not based on sample size, power or statistical effect sizes. Equally, no risk of bias comparisons of the studies could suggest a pattern. Despite this, our findings are in line with pre-existing literature (81–84).

Conclusion

This systematic review offers an extensive overview of which individual implementation interventions that may be effective in musculoskeletal healthcare. Our data suggests that the implementation interventions “Conduct local consensus discussions”, “Make training dynamic”, “Distribute educational materials” and “Conduct educational meetings” may have a tendency towards a statistically significant positive effect in favour of the intervention group amongst HCPs concerning the outcome domain “Adherence to implemented intervention”. For the remaining HCP outcome domains and the cost-effectiveness outcome domain the effects are unknown across all implementation interventions due to discrepancies between studies. For patient outcome domains, it appears that no implementation interventions yields a statistically significant positive effect in favour of the intervention group. Most of the included studies were determined to have either some concerns or high risk of bias and had a high methodological heterogeneity. These results should

therefore be interpreted with caution. For the field of implementation science to draw stronger conclusions and advance our knowledge about implementation strategies and interventions, it is important to conduct high-quality studies with detailed reporting of the methodology, including a comprehensive description of implementation strategies and interventions as well, as a well-defined rationale while utilising a standardised nomenclature. Additionally, it is important to allow for the investigation of behaviour change mechanisms to draw stronger conclusions and contribute to the advancement of knowledge in the field.

Declarations

Ethics approval and consent to participate

Not applicable.

Consent for publication

Not applicable.

Availability of data and materials

All data generated during this study are included either within the text or as an additional file.

Competing interests

The authors declare that they have no competing interests.

Funding

None of the authors received any funding for this project.

Authors' Contributions

All authors drafted the first protocol. PBH, MB, MSN, JFJ and KDL drafted the literature searches. PBH, MB, MSN, and KDL conducted the screening of all studies. PBH, MB, and MSN extracted all data. PBH, MB, MSN, MSR, and KDL participated in the data analysis. PBH, MB, and MSN,

drafted the first draft and first review was made by MSR and KDL. Finally, all authors have thoroughly reviewed and approved the final submitted version of the manuscript.

Acknowledgements

Not applicable.

Contributions to the literature:

- ② This systematic review provides an overview of implementation interventions and the statistically significant positive effect in favour of the intervention groups within musculoskeletal healthcare.
- ② The effect of implementation interventions on most outcome domains varies substantially, however, there seem to be a potential positive statistically significant effect of some implementation interventions for outcomes measuring the HCP outcome domain “Adherence to implemented intervention”.
- ② This systematic review highlights the poor quality of trials found in the literature and advise future authors to extensively describe the implementation strategies and interventions and the rationale hereof in detail and utilising a standardised nomenclature to ensure consensus.

● = Statistically significant positive effect in favour of intervention group; ● = No statistically significant positive effect in favour of intervention group; ● = Mixed findings of statistically significant effect; ● = Unknown statistically significant effect

Figure 2
Mapping Implementation Interventions for Musculoskeletal Healthcare. Map of significance illuminating the effect of implementation interventions for musculoskeletal healthcare. Types of implementation interventions are listed within the rows, and outcome domains are listed in the columns. The size of the circles and the number in the circles indicates the number of RCTs identified. A lack of RCTs results in missing circles in the corresponding fields.

Tables

Table 1

Table 1						
Study Characteristics of all Included Studies						
Author, Year Study Design Country of Origin	HCP's (n) Patient condition (n) Clinical setting (n)	Study Implementation Interventions Waltz's Implementation Clusters	Comparator	Primary Outcomes	Findings	Overall risk of bias
Becker et al. 2008 Cluster RCT Germany	GP's (126) Patients with LBP (1378) Primary care (118 practices)	<u>Guideline Implementation group.</u> Three interactive seminars + Individual educational visits by study nurses Develop stakeholder interrelationships + Train and educate stakeholders <u>Guideline implementation + Motivational Counselling group.</u> In addition, 20-hour training in motivational counselling In addition: Use evaluative and iterative strategies	Received guidelines via mail.	Patients: <i>Function</i>	No statistically significant difference in guideline implementation group versus comparator on functional capacity (p=0.120) Statistically significant difference in guideline implementation + motivational counselling group versus comparator on functional capacity (p=0.032)	!
Becker et al. 2012 Cost-effectiveness analysis of a cluster RCT Germany	GP's (126) Patients with LBP (1322) Primary care (118 practices)	This cost-effectiveness study was performed using data from Becker et al. 2008. For a description of the implementation strategies and Waltz's Classification, see Becker et al. 2008.		Cost-Effectiveness	For Indirect cost the GI and GI+MC group had lower costs than the control group, with a mean difference of -332.51€ (95% CI: -650 to -44) and -302.83€ (95% CI: -621 to -6). For total cost the GI+MC group had statistically significant lower costs than the control group MD -482.59€ (95% CI: -983 to -54)	-
Bekkering et al. 2005 (a) Cluster RCT The Netherlands	Physiotherapists (113) Patients with LBP (500) Primary care (68 practices)	Guideline by mail + four forms to self-evaluate and facilitate discussion. an article concerning the guidelines + two 2.5-hour training sessions + two 2-hour preparation. Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders + Support clinicians	As the intervention group, but without the 2.5-hour training sessions and preparation	Healthcare Professionals: <i>Adherence to implemented intervention</i>	Statistically significant effect in favour of intervention group on Correctly limited treatment sessions OR 2.39 (95% CI: 1.12 to 5.12) More frequent functional goalsetting OR 1.99 (95% CI: 1.06 to 3.72) Frequency of active interventions: OR 2.79 (95% CI: 1.19 to 6.55) Gave adequate advice with an OR of 3.59 (95% CI: 1.35 to 9.55) All four recommendations with an OR 2.05 (95% CI: 1.15 to 3.65)	-
Bekkering et al. 2005 (b) Cluster RCT The Netherlands	Physiotherapists (113) Patients with LBP (500) Primary care (68 practices)	This study was performed using data from Bekkering et al. 2005 (a). For a description of the implementation strategies and Waltz's Classification, see Bekkering et al. 2005 (a).		Patients: <i>Function Pain Workability</i>	No difference between the 2 groups on physical functioning (p>0.05) or on pain (p>0.05) at 12 months.	-
Bishop et al. 2006 RCT Canada	Family physicians (462)	<u>Group 2:</u> Received copy of the guidelines + "guideline reminder letter." Train and educate stakeholders + Support clinicians	<u>Group 1:</u>	Healthcare Professionals:	Compared to control, no statistical significance in either group in recorded history or physical findings (p=0.89, p=0.90) medication (p=0.14,	-

	Patients with LBP (428) Primary care	<u>Group 3:</u> In addition, patients received lay version of guidelines. In addition to Group 2: Engage consumers	Received no implementation intervention.	<i>Adherence to implemented intervention</i>	p=0.08) supervised exercise (p=0.11, p=0.18) return to work (p=0.07, p=0.14) Statistically significant difference in not using extended bed rest in group 2 (p=0.05) not using continued use of passive therapies (p=0.04, p=0.05) and recommended exercise in group 3(p=0.05)	
Bruyndonckx et al. 2018 Cluster RCT Belgium	GP's (4530) Patients with LBP Primary care (3401 practices)	20 minutes academic detailing. Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Prescription of analgesics</i>	Statistically significant step change in "Odds of being reimbursed for a recommended NSAID when reimbursed for any NSAID" p<0.01 No statistically significance on any other measure.	-
Bussières et al. 2010 RCT Switzerland	Chiropractors (160) Patients with LBP Private practice	<u>Intervention group 1 (IG1)</u> 20-minute lecture + 90-minute educational workshop Develop stakeholder interrelationships + Train and educate stakeholders <u>Intervention group 2 (IG2)</u> 20-minute lecture + 90-minute educational workshop + Reminder Develop stakeholder interrelationships + Train and educate stakeholders + Support clinicians <u>Intervention group 3 (IG3)</u> 20-minute lecture + 90-minute educational workshop Develop stakeholder interrelationships + Train and educate stakeholders	20-minute lecture + A chiropractic technique seminar on spinal pain	Healthcare Professionals: <i>Uptake of knowledge</i>	Scores for the pre-test and the final test for all four groups were not significantly different (p = 0.348).	!
Chipchase et al. 2016 RCT Australia	Physiotherapists (23) Patients with neck pain (158) Physiotherapy Practice	Two-day workshop + five-hour follow-up session one month later Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders	Same interventions, only without follow-up session.	Healthcare Professionals: <i>Uptake of knowledge</i> Patients: <i>Function</i>	No significant between-group differences were identified on practice behaviour (p>0.05). NDI were not statistically significant between groups. (p=0.11)	-
Cleland et al. 2009 RCT The United States of America	Physiotherapists (30) Patients with neck pain (1199) Physiotherapy practices	2-day (4-hours a day) continuous education course + two 1.5-hour educational meetings + 1-hour outreach visit. Provide interactive assistance + Train and educate stakeholders	Comparator attended course, no follow-ups.	Patients: <i>Function</i> <i>Pain</i>	Statistically significant difference between groups post-test on function (p=0.013). No statistically significant difference between groups post-test on pain (p=0.088)	!
Coombs et al. 2021 Stepped wedge cluster RCT Australia	Rheumatologists, physiotherapists and emergency physicians (269) Patients with LBP (4491) Primary care	Education seminars + development and distribution of educational material + provision of non-opioid pain management + access to fast-track referrals to outpatient services + audit and feedback. Use evaluative and iterative strategies + Adapt and tailor to context + Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Referral to imaging</i>	The intervention did not significantly reduce the odds of lumbar imaging OR=0.77 (95% CI of 0.47 to 1.26)	-
Dey et al. 2004 Cluster RCT England	GP's Patients with LBP (2187) Primary care (24 health centers)	Facilitated structured interactive discussion + Posters developed and distributed. Use evaluative and iterative strategies + Provide interactive assistance + Adapt and tailor to context + Develop stakeholder interrelationships + Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Adherence to implemented intervention</i> <i>Referral to imaging</i> <i>Referral to secondary care</i> <i>Prescription of analgesics</i>	No statistical significance on: Referral to X-ray: p=0.62, Issued a sickness certificate: p=0.74, Prescribed opioids or muscle relaxants: p=0.99, Referred to secondary care: p=0.12	!

Eccles et al. 2001 Cluster RCT England and Scotland	GPs (162) Patients with LBP and knee pain (1693) Primary care (48 practices)	<u>Audit & feedback group:</u> Guidelines sent via mail + audit and feedback. Use evaluative and iterative strategies + Train and educate stakeholders <u>Reminder message group:</u> Guidelines sent via mail + reminders attached to reports of radiograph. Train and educate stakeholders + Support clinicians <u>Audit, feedback & Reminder message group:</u> This group received a combined intervention of the implementation strategies.	Comparator only received guidelines via mail.	Healthcare Professionals: <i>Referral to imaging</i>	Statistically significant absolute change of educational reminder messages for lumbar spine radiographs (p<0.05) and knee radiograph requests(p<0.05). No statistically significant change in audit and feedback group. There was no statistically significant increased effect of receiving both interventions for both types of radiographs.	!
Engers et al. 2005 Cluster RCT The Netherlands	GP's (67) Patients with LBP (531) Primary care	2-hour workshop + Educational material + tool for patient education Train and educate stakeholders + Support clinicians	Received no implementation intervention.	Healthcare Professionals: <i>Adherence to implemented intervention</i> <i>Referral to secondary care</i> <i>Prescription of analgesics</i>	The intervention did not promote statistical significance on any outcomes between groups.	!
Evans et al. 2010 Cluster RCT United Kingdom	Physiotherapists (824); chiropractors (336); and osteopaths (598) Patients with LBP Primary care	Printed information package posted to the participants with evidence-based management of acute LBP, based on the latest guidelines. Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Adherence to implemented intervention</i>	Statistically significant difference between groups in advice about activity (p=0.028) and work (p=0.012) but not on bed rest (p=0.078)	!
French et al. 2013 Cluster RCT Australia	GPs (112) Patients with LBP Primary care (92 practices)	Two facilitated, interactive, educational 3-hour workshops + a DVD. Use evaluative and iterative strategies + Provide interactive assistance + Adapt and tailor to context + Develop stakeholder interrelationships + Train and educate stakeholders	Comparator received a printed copy of the guideline.	Healthcare Professionals: <i>Uptake of knowledge</i> <i>Referral to imaging</i>	Statistically significance on vignettes on X-ray adherence (p=0.045), imaging adherence (p=0.000) and activity adherence (p=0.001) There was no statistical significance on bed-rest adherence p=0.354 X-ray referrals (p=0.211) or CT-scan referrals (p=0.598) or both (p=0.244)	-
French et al. 2022 Cluster RCT Australia	Physiotherapists (182); Chiropractors (88) Patients with LBP (1358) Primary care (104 practices)	Full day symposium delivered by opinion leaders + Educational materials were developed and distributed + reminders. Use evaluative and iterative strategies + Adapt and tailor to context + Develop stakeholder interrelationships + Train and educate stakeholders + Support clinicians	Comparator received a printed copy of the guideline.	Healthcare Professionals: <i>Referral to imaging</i> Patients: <i>Function</i>	There was no statistically significant difference between groups in the odds of patients being referred for X-ray. There was no important clinical difference in LBP-specific disability between groups.	-
Goldberg et al. 2001 Cluster RCT The United States of America	Spinal surgeons Primary physicians Patients with LBP Primary care (10 communities inhabited by 245.710 citizens)	Opinion leaders was expected to share information + continued medical education + academic detailing with posters and pamphlets. Use evaluative and iterative strategies + Develop stakeholder interrelationships + Train and educate stakeholders + Change infrastructure	Received no implementation intervention.	Healthcare Professionals: <i>Adherence to implemented intervention</i>	Statistical significance in the intervention period, compared to the baseline period observed rate of surgeries (p=0.01)	-
Hoeijenbos et al. 2005 Cluster RCT The Netherlands	Physiotherapist (113) Patients with LBP (500) Primary care (68 Practices)	This study was performed using data from Bekkering et al. 2005 (a). For a description of the implementation strategies and Waltz's Classification, see Bekkering et al. 2005 (a).		Patients: <i>Quality of life</i> Cost-Effectiveness	No statistically significant difference of quality of life in the intervention group compared to control (p>0.05). Statistically significant lower medical costs at 6 weeks for the intervention group compared to control (p=0.026)	!

					No significant cost differences were found at 12, 26 and 52 weeks between the groups (p= 0.051, p=0.818, p=0.477).	
Jensen et al. 2017 Cluster RCT Denmark	GP's Patients with LBP (475) Primary care (60 practices)	This study was performed using data from Riis et al. 2016. For a description of the implementation strategies and Waltz's Classification, see Riis et al. 2016.		Cost-Effectiveness	The adjusted cost regression did not show a statistically significant average cost saving per patient of €169 (95% CI: -€661 to €323). The adjusted QALY decrement regression did not show a statistically significant average loss of 0.0065 QALY (95% CI: -0.036 to 0.023) per patient over the 12 months of follow-up.	
Leonhardt et al. 2008 RCT Germany	GP's (126) Patients with LBP (1378) Primary care (118 practices)	This study was performed using data from Becker et al. 2008. For a description of the implementation strategies and Waltz's Classification, see Becker et al. 2008.		Patients: <i>Physical activity</i>	No statistically significant difference on physical activity between groups at any timepoint.	
Maas et al. 2015 Cluster RCT The Netherlands	Physiotherapists (149) Patients with LBP Communities of practice	<u>Peer assessment (PA) group:</u> Received link to guidelines + E-mailed program guide + four 3-hour sessions with focus on peer assessment. Provide interactive assistance + Train and educate stakeholders	<u>Case discussion (CD) group:</u> Received link to guidelines + E-mailed program guide + four 3-hour sessions with focus on discussion. Train and educate stakeholders + Develop stakeholder	Healthcare Professionals: <i>Uptake of knowledge</i>	Significant difference on guideline adherence (p=0.031) and awareness of performance (p=0.01) in favour of PA group. No significant difference on groups in reflective practice (p=0.96).	
Mortimer et al. 2013 Cluster RCT Australia	GP's (112) Patients with LBP Primary care (92 practices)	This study was performed using data from French et al. 2013. For a description of the implementation strategies and Waltz's Classification, see French et al. 2013.		Cost-Effectiveness	Adjusted incidence rate ratios suggest that total cost per GP was not statistically significant (p = 0.578). Incremental effects showed that exposure to the intervention reduced total cost per GP by \$375.55 but was not statistically significant (p = 0.605).	
Moseng et al. 2019 Stepped wedge cluster RCT. Norway	GP's (40) Physiotherapists (37) Patients with hip and knee OA (393) Primary care	One day seminar Train and educate stakeholders	No intervention because of a Stepped wedge design	Patients: <i>Patient adherence</i>	Patient-reported data showed a statistically significant higher uptake for all the core treatment components for the intervention group compared to the control group (p<0.05).	
Murray et al. 2015 Cluster RCT Ireland	Physiotherapists (24) Patients with LBP (24) Secondary care	1-hour education session + two 4-h sessions of communication skills training + individual emails. Develop stakeholder interrelationships + Train and educate stakeholders	Comparator only got the 1-hour education session.	Healthcare Professionals: <i>Adherence to implemented intervention</i>	Between group difference in favour of intervention group on Health Care Climate Questionnaire (p<0.001).	
O'Connor et al. 2022 Cluster RCT Australia	GP's (3819) Patients with musculoskeletal conditions Primary care	Individualized audit and feedback (once, twice, visually enhanced, and normal) Use evaluative and iterative strategies + Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Referral to imaging</i>	Statistically significant rate of imaging referrals in the intervention groups compared to the control (p<0.001) No statistically significant difference between intervention groups.	
Peter et al. 2013 RCT The Netherlands	Physiotherapists (248) Patients with hip and knee OA Private practice	Interactive workshop + two educational + examined real patients + feedback + discussion. Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders	Presentation on the guideline development process and two cases.	Healthcare Professionals: <i>Adherence to implemented intervention</i> <i>Uptake of knowledge</i>	Statistically significant difference between groups on the "Quality indicator for physiotherapy care in hip and knee osteoarthritis" questionnaire (p=0.024). No statistically significant difference between groups on self-made uptake questionnaire (p=0.278).	

Peter et al. 2015 RCT The Netherlands	Physiotherapists (319) Patients with hip and knee OA Primary care	Interactive workshop + two educational + examined real patients + feedback + discussion. Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders	Comparator received the same educational course 4 months after the first course	Healthcare Professionals: <i>Uptake of knowledge</i>	Statistically significant difference between groups on both times points in adherence questionnaire (p<0.001, p=0.004) and knowledge questionnaire (p<0.001, p=0.004)	-
Rebeck et al. 2006 Cluster RCT Australia	Physiotherapists (27) Patients with whiplash (103) Primary care	8-hour interactive workshop + Local opinion leaders + follow-up 2-hour educational outreach visits Develop stakeholder interrelationships + Train and educate stakeholders	Comparator received a mail with the guidelines.	Healthcare Professionals: <i>Adherence to implemented intervention</i> <i>Uptake of knowledge</i> <i>HCP satisfaction</i> Patients: <i>Function</i> <i>Patient satisfaction</i>	Self-rated guideline understanding (p=0.001) and for advice "Reassure patient" p= 0.05 "Advise to act as usual" p= 0.04 but not for "Prescribe function" p= 0.22 "Prescribe exercise" p= 1.00 "Prescribe medication" p= 0.10 Statistically significant difference, compared to the control, for uptake (p=0.001). No statistically significant effect on function (p=0.87, p=0.85, p=0.95), patient satisfaction (p=0.69, p=0.87, p=0.93) and global perceived effect (p=0.95)	-
Riis et al. 2016 Cluster RCT Denmark	GP's (60) Patients with LBP (1101) Primary care	Regional information meeting + outreach visits + follow-up Develop stakeholder interrelationships + Train and educate stakeholders + Support clinicians + Engage consumers + Change infrastructure	Regional information meeting about the guidelines.	Healthcare Professionals: <i>Referral to secondary care</i>	Statistically significant reduced odds in the intervention group, compared to control (p= 0.020)	!
Sanders et al. 2017 Cluster RCT The Netherlands	GP's (42) Patients with LBP (226) Primary care	Two 2.5-hour training sessions + decision aid + desktop tool + personalized feedback on videotaped consultation Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Adherence to implemented intervention</i>	Statistically significant mean difference between group in favour of intervention on Level of shared decision making (p<0.05) and Level of positive reinforcement (p<0.05)	!
Schectman et al. 2003 Cluster RCT USA	Clinicians (85) Patients with LBP (2020) Primary care	Guidelines developed and distributed + 90-minute educational outreach by local opinion leaders + audit and feedback + follow-up phone call and visit + reminder. Use evaluative and iterative strategies + Develop stakeholder interrelationships + Train and educate stakeholders + Support clinicians	Received no implementation intervention.	Healthcare Professionals: <i>Referral to imaging</i> <i>Referral to secondary care</i>	Guideline-consistent behaviour increased by 5.4% in the intervention group. Declines 2.7% in the control group (p = 0.046). Overall decline in raw utilization of services of 8.5% in the intervention group versus 0.6% in the control group (p = 0.042).	!
Scheel et al. 2002 Cluster RCT Norway	GP's. Patients with LBP (6179) Primary care (65 municipalities)	<u>Passive strategy group:</u> Targeted information to GP's + checkbox in the form for reporting sick leave + reminder + desktop summary clinical guidelines. Use evaluative and iterative strategies + Train and educate stakeholders + Support clinicians <u>Proactive strategy group:</u> In addition; Proactive resource support person. Use evaluative and iterative strategies + Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders + Support clinicians	Received no implementation intervention.	Healthcare Professionals: <i>Adherence to implemented intervention</i>	Statistically significant different net increase usage of Active Sick Leave in the proactive group, compared to the passive and the control group (p= 0.018).	-
Schröder et al. 2022 Stepped cluster RCT Sweden	Physiotherapists (98) Patients with LBP (500) Primary care	2-day workshop (13.5-hour) Provide interactive assistance + Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Referral to secondary care</i> <i>Referral to imaging</i>	Statistically significant decrease in medical imaging (p=0.011) but not in referrals to specialist (p=0.257)	+
Simula et al. 2021 Cluster RCT Finland	Physiotherapists, nurses and physicians	Booklet was developed and distributed +30 min session on its use. Train and educate stakeholders	Received no implementation intervention.	Healthcare Professionals: <i>Referral to imaging</i> Patients:	Statistically significant decreased odds of referral to imaging (p=0.007) referrals to radiographs (p=0.016) referrals to MRI (p=0.001) referrals to MRI + CT (p=0.014) but not on "Patient Reported	-

				<i>Function</i>	Outcome Measurement Information System T-Score” (p=0.935)	
Stevenson et al. 2004 Cluster RCT England	Patients with LBP (415) Primary care (8 Health centers) Physiotherapists (30) Patients with LBP Community Trust	Interactive evidence-based educational program + utilized opinion leaders + peer group teaching + Two times 2.5-hour sessions on critical appraisal, literature searching skills and management of acute LPB and chronic LPB. Develop stakeholder interrelationships + Train and educate stakeholders	Received education session on different condition than studied.	Healthcare Professionals: <i>Uptake of knowledge</i>	Therapist has support to undertake EPB: Intervention group: Baseline 47% - 6 months: 81% Control group: Baseline: 38% - 6 months: 45% Confidence in critical appraisal: Intervention group: Baseline 24% - 6 months: 62% Control group: Baseline: 15% - 6 months: 50%	!
Stevenson et al. 2006 Cluster RCT England	Physiotherapists (30) Patients with LBP (306) Primary care	This study was performed using data from Stevenson et al. 2004. For a description of the implementation strategies and Waltz’s Classification, see Stevenson et al. 2004.		Healthcare Professionals: <i>Adherence to implemented intervention</i> <i>Uptake of knowledge</i>	No statistical significance on any of the primary outcomes.	-
Suman et al. 2018 Cluster RCT The Netherlands	GP’s (53) Patients with LBP (5130) Primary care (25 practices)	Multidisciplinary continuing medical education in communications interprofessionally and with patients were main themes as means to reduces referral, + educational materials + interactive website. Train and educate stakeholders + Engage consumers	Received no implementation intervention	Healthcare Professionals: <i>Referral to imaging</i> <i>Referral to secondary care</i>	No significant difference between groups over time on the number of total referrals to imaging and medical specialist care (p>0.05).	!
Van Dulmen et al. 2014 Cluster RCT The Netherlands	Physiotherapists (90) Patients with LBP Communities of practice	<u>Problem-Based Peer Assessment (PA)</u> : Four 2-hour meetings + Peer-assessment + feedback. Provide interactive assistance + Develop stakeholder interrelationships + Train and educate stakeholders	<u>Case-Based Discussion (CD)</u> Four 2-hour meetings + case discussions. Develop stakeholder interrelationships + Train and educate stakeholders	Healthcare Professionals: <i>Uptake of knowledge</i>	Statistically significant increase in questionnaire in the peer-assessment group, compared to the case-based discussions group (p=0.001)	!

Abbreviations: GP: General practitioners; LBP: Low back pain; NSAID: Non-steroidal anti-inflammatory drug; OR: Odds ratio; CI: Confidence interval; MD: Mean difference; QALY: Quality adjusted life years; MRI: Magnetic resonance imaging; CT: Computerized tomography; EPB: Evidence based practice.
