17	Abstract
18	
19	Myopia, projected to affect half of the global population by 2050, is a growing healthcare
20	concern. Chronotype, an output of the human biological clock, and sleep parameters have
21	been associated with several diseases, including myopia. We explored the connection
22	between refractive errors and sleep and circadian rhythm parameters by employing a sample
23	of 71,016 adults who completed the Munich Chronotype Questionnaire in the Estonian
24	Biobank. After accounting for possible confounders, such as age, sex, education level, and
25	duration of daylight exposure, we observed that individuals with late chronotype, characterised
26	by a delayed sleep-wake pattern on free days, had higher odds for myopia. In contrast, early
27	chronotype was associated with hyperopia. Furthermore, increased social jet lag and reduced
28	sleep duration were associated with both myopia and hyperopia. These results emphasise the
29	complex interplay between circadian rhythms and sleep in refractive development, with
30	potential implications for public health and clinical practice.

NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.

#### 31 Introduction

### 32

33 Myopia, or short-sightedness, is an ocular condition characterised by impaired distant vision. 34 It has increasingly been recognised as a substantial global public health concern as its 35 prevalence is rising rapidly and is estimated to reach 50% by 2050<sup>1</sup>. During eye development, 36 the length of the eye and the structures that bend incoming light rays, the cornea, and the 37 crystalline lens, must become balanced to focus light on the retina, where visual signalling is 38 initiated. Myopia results from a failure in this refractive development process, caused primarily 39 by excessive eyeball elongation, leading to light entering the eye and focusing in front of the 40 retina. The opposite condition, where the eye remains too short, is termed hyperopia or long-41 sightedness. Although refractive development occurs during childhood and is complete by early adulthood, the shorter axial length in hyperopia is initially compensated by an elastic 42 crystalline lens<sup>2</sup>. Thus, the hyperopes remain asymptomatic and do not receive the diagnosis 43 until later in adulthood<sup>2</sup>. Although myopia and hyperopia can be corrected with spectacles or 44 45 contact lenses, the mechanical strain induced by the excessive elongation of the eye in myopic 46 individuals increases the susceptibility to severe ocular pathologies that could jeopardise 47 vision in later stages of life. These include myopic macular degeneration, retinal detachment, 48 glaucoma, and cataracts<sup>3</sup>. This not only impairs the quality of life of affected individuals but 49 also imposes substantial social and economic costs<sup>4</sup>. Given the considerable impact of 50 myopia, a better understanding of the mechanisms governing its development and associated 51 risk factors is required.

52 Several studies have suggested a connection between refractive development and 53 circadian rhythms. For example, the axial length of the eye displays rhythmicity over a day in 54 humans<sup>5</sup> as well as in chickens<sup>6</sup>. Furthermore, the rhythmicity of axial length is disrupted in chickens developing myopia<sup>7</sup>. Additionally, a meta-analysis of genome-wide association 55 studies (GWAS), which included over 500,000 study subjects, revealed that genes associated 56 with myopia were enriched for genes regulating circadian rhythms<sup>8</sup>. These findings have led 57 58 to the analysis of behavioural circadian rhythms in myopia. Chronotype, an individual's 59 inherent predilection for sleep-wake timing, is dictated by the individual's biological clock<sup>9</sup>. This 60 preference spans a spectrum from early chronotypes, or "larks" (individuals with a propensity for early rising and retiring), to late chronotypes, or "owls" (individuals who favour delayed 61 sleep and wake times)<sup>9</sup>. The establishment of activity patterns is a result of the extensive 62 63 interaction between the biological clock, the natural cycle of light and darkness, as well as 64 social schedules, often referred to as the social clock<sup>9</sup>. Misalignment of the biological and social clock, termed social jet lag (SJL)<sup>10</sup>, is associated with various adverse health outcomes, 65 66 including metabolic and cardiovascular diseases<sup>11</sup>. SJL is strongly predicted by chronotype<sup>12</sup> 67 as later chronotype is associated with increased SJL. Furthermore, chronotype is intricately 68 linked to other sleep parameters, as late chronotype has been associated with worse sleep

guality<sup>13-15</sup> and shorter sleep duration<sup>13</sup>. Collectively, the parameters pertaining to sleep and

quality<sup>13-15</sup> and shorter sleep duration<sup>13</sup>. Collectively, the parameters pertaining to sleep and
circadian rhythms are complexly interconnected, thereby posing challenges to their
investigation.

72 Various sleep parameters, particularly bedtime, sleep quality, and duration, have been 73 investigated in myopia but, thus far, have yielded mixed results. Several studies have found that children with myopia sleep later than children without myopia<sup>16–19</sup>, while some have found 74 75 no association<sup>20–23</sup>. Myopia has been associated with lower sleep guality in some studies<sup>16,24</sup>, while no associations have been found in others<sup>25</sup>. Myopia has been associated with shorter 76 77 sleep duration<sup>16,26</sup>, while other investigations have not confirmed this finding<sup>17,20-25</sup>. 78 Chronotype has also been studied in the context of myopia, but no definitive associations have 79 been established. Some studies have reported an association between myopia and late chronotype<sup>16,27,28</sup>, while in other reports, the circadian rhythms of myopes and non-myopes did 80 not differ<sup>29</sup> and self-reporting as "morning" or "evening" type was not associated with myopia 81 progression<sup>18</sup>. In conclusion, the existing research presents a mosaic of findings suggesting 82 83 potentially complex relationships between circadian rhythms and refractive errors.

Leveraging data from the Estonian Biobank (EstBB), we adopted an exhaustive 84 85 methodology to explore the intricate relationships among refractive errors, chronotype, and 86 sleep parameters. We first characterised chronotype and sleep parameters obtained with the 87 Munich Chronotype Questionnaire (MCTQ)<sup>9</sup> in the EstBB. Using logistic regression, we then 88 investigated the associations between chronotype, SJL and sleep duration with myopia and 89 hyperopia in ~71,000 individuals aged between 18 and 70 years. We found that late chronotype was associated with myopia, while early chronotype was linked with hyperopia. 90 Increased SJL and shorter sleep duration were associated with increased odds for both 91 92 conditions. These associations remained significant after accounting for factors shown to be associated with myopia in previous studies, such as time spent in daylight<sup>30–33</sup>, the highest 93 level of education, birth season<sup>34,35</sup> and photoperiod at birth<sup>34</sup>, and the first ten genetic principal 94 95 components.

### 98 Results

99

# 100 Characterisation of chronotype and sleep parameters in the Estonian Biobank

101

The MCTQ<sup>9</sup> includes questions about daily sleep habits, separately for work and work-free days, and was filled out by 136,618 EstBB participants. MCTQ defines chronotype as the midpoint of sleep on work-free days adjusted for sleep debt accumulated over workdays (midpoint of sleep on free days, sleep debt corrected, MSFsc). With MCTQ, chronotype can

106 only be accurately estimated for those who have not done any shift work over the previous three months and who wake up without an alarm clock on free days<sup>9</sup>. Individuals not fulfilling 107 these criteria were not included in the analyses presented below (see Supplementary Fig. 1 108 109 for sample selection workflow). SJL is defined as the absolute difference between the midpoint 110 of sleep on free days and the midpoint of sleep on workdays<sup>9</sup>. Weekly average sleep duration 111 was calculated based on the sleep duration on working days and free days<sup>9</sup>.

112 In our study sample, chronotype could be calculated for 79,247 participants aged 113 between 18 and 80 years. We observed significant variability in chronotype and sleep 114 parameters across age groups between sexes (Fig. 1a-c, Table 1). In line with previous 115 reports<sup>12,36</sup>, chronotype was significantly later in young adults, and it became gradually earlier 116 with increasing age. Males exhibited later chronotypes until the mid-40s and became earlier chronotypes from the 50s, similar to what has been documented previously<sup>12,36</sup>. As shown 117 118 before<sup>10,12</sup>, SJL decreased with age and became negligible by mid-60s. As late chronotype is 119 associated with increased SJL, one would expect to see similar sex differences in chronotype 120 and SJL. Instead, we found that SJL was not significantly different between males and females in early adulthood but was larger in females from 30s to 60s. Consistent with previous 121 reports<sup>37-39</sup>, the average sleep duration decreased with age. Interestingly, we detected a 122 123 subsequent increase in sleep duration from the mid-60s, which coincides with the statutory 124 retirement age in Estonia. Females slept longer than males throughout early adulthood to the 125 mid-50s, driven primarily by longer sleep on weekends (Supplementary Fig. 2c). An additional 126 determinant of an individual's sleep patterns is the duration of daylight exposure as an increased daylight exposure has been associated with an earlier chronotype<sup>40</sup>. We found that 127 128 males reported spending significantly more time in daylight across all ages (Fig. 1d), 129 suggesting that other factors, not daylight exposure, may account for chronotype differences 130 between males and females. Other sleep-related variables of MCTQ are reported in 131 Supplementary Fig. 2.

To understand to what extent chronotype, SJL, sleep duration, and daily light exposure 132 133 relate to each other, we analysed the correlation between these variables. We detected a 134 moderate positive correlation between chronotype and SJL (Spearman  $r_s = 0.526$ ) but no 135 correlation between the other variables (Fig. 1e).

136

### 137 Association between sleep and circadian rhythm parameters with refractive errors 138

139 Next, we wanted to analyse the associations between chronotype and sleep parameters with 140 refractive errors. As myopia and hyperopia are opposite conditions-myopia is associated 141 primarily with an increased ocular axial length and hyperopia with a reduced axial length<sup>2</sup>, this 142 approach allows us to investigate factors predisposing eyes to abnormal growth and the 143 factors affecting the directionality of this eye growth. We also included in our analysis factors

known to be associated with myopia, including time spent in daylight<sup>30–33</sup>, the highest level of 144 education, birth season<sup>34,35</sup> and photoperiod at birth<sup>34</sup>. We only included participants aged  $\leq$ 70 145 as age-related diseases, e.g. ocular and neurological conditions and eye diseases, can 146 influence one's sleep patterns and circadian rhythms<sup>41,42</sup>. The workflow for obtaining the 147 148 sample is presented in Supplementary Figure 1, and descriptive statistics for the obtained 149 sample and refractive error subgroups are presented in Table 2.

150 Myopia frequency was highest in the youngest age group, reaching 37% in the 18-25-151 year-olds, and decreased with age; conversely, the frequency of hyperopia increased with age 152 (Fig. 2a). The distribution of myopia and hyperopia across ages follows a similar pattern as the estimated prevalence of these refractive errors in Europe<sup>43</sup>. While a total of 12% of males 153 154 had hyperopia and 19% of males had myopia, the proportion of females with these refractive errors was higher—16% and 29%, respectively (Fig. 2b). Of all myopes, 54% had a higher 155 156 education degree, this figure was 44% amongst those with no refractive error and 36% in 157 hyperopes (Fig. 2c). The opposite trend was evident for basic and middle education, which 158 were more prevalent in hyperopes and people with no refractive error (Fig. 2c). The distribution 159 of birth season and photoperiod at birth was uniform in myopes, hyperopes and those without 160 a refractive error (Table 2). There were significant differences in chronotype, SJL, average 161 sleep duration and average daily daylight exposure in myopes, hyperopes and individuals with 162 no refractive error across ages (Fig. 2d-g, Table 2).

163 Next, we used logistic regression analysis to determine whether circadian rhythm and 164 sleep parameters were associated with refractive errors. We first conducted adjusted 165 univariate models to examine the individual effects of each independent variable on the 166 dependent variables myopia and hyperopia while controlling for age, age squared, and sex 167 (Supplementary Table 1). All three sleep and circadian rhythm parameters, chronotype, SJL 168 and sleep duration, were associated with both myopia and hyperopia. Additionally, education 169 level and time spent in daylight showed significant associations with both myopia and 170 hyperopia, and the autumn birth season and longest photoperiod were associated with higher 171 odds of hyperopia compared to the winter birth season and shortest photoperiod.

172 To further assess whether the detected associations are independent of each other, 173 we employed multivariate models that incorporated all these factors. As refractive errors have 174 a considerable genetic predisposition<sup>8</sup>, we also included in our analysis the first ten genetic 175 principal components calculated from the genetic data of the EstBB participants. The 176 relationships between all studied sleep and circadian parameters remained significant and 177 with similar directionality as in the adjusted univariate analyses (Table 3). Chronotype 178 exhibited an opposite association with refractive errors—one hour later chronotype increased 179 the odds for myopia (OR 1.03, 95% CI 1.01–1.05) and decreased odds for hyperopia (OR 180 0.95, 95% 0.93–0.98). SJL and sleep duration influenced the odds of myopia and hyperopia 181 in a similar direction. Larger SJL increased the odds for both myopia and hyperopia (per one

182 hour of larger SJL: OR 1.04, 95% CI 1.02–1.07 for myopia; OR 1.09, 95% CI 1.05–1.13 for 183 hyperopia). Shorter sleep was associated with both myopia and hyperopia (per one hour 184 longer sleep duration per day: OR 0.95, 95% CI 0.93–0.97 for myopia, OR 0.92, 95% CI 0.90– 185 0.94 for hyperopia). As expected, more time in daylight decreased the odds for myopia (OR 186 0.95, 95% CI 0.93–0.97 per additional hour/day). Interestingly, the opposite was evident for 187 hyperopia, more time outdoors was associated with higher odds for hyperopia (OR 1.06, 95%) 188 CI 1.04–1.07 per additional hour/day). As has been shown previously, a higher education level 189 increased myopia odds (higher education compared to middle education, OR 1.42, 95% CI 190 1.36–1.47). Again, the opposite was detected for hyperopia, where higher education was 191 associated with decreased odds (OR 0.73, 95% CI 0.70–0.77). Birth season and photoperiod 192 at birth were not significantly associated with either myopia or hyperopia in the multivariate 193 models.

194 For sensitivity analysis, we applied the multivariate model to a sample including 195 participants aged >45 years only. We chose this age as hyperopia often goes undiagnosed 196 until around that age, as the elastic lens compensates for the shorter ocular axial length<sup>2</sup>. We 197 found that the associations with chronotype, SJL, sleep duration, time spent in daylight, and 198 education remained significant with the same directionality (Supplementary Table 2). 199 Collectively, these findings suggest that processes related to SJL and sleep duration are 200 associated with refractive errors in general. In contrast, chronotype is associated with the 201 directionality of refractive error development, revealing a complex relationship between 202 circadian rhythms and sleep and refractive errors.

203

204

#### 205 Discussion

206

207 In this study, we analysed the associations between refractive errors and circadian rhythm 208 and sleep parameters using an extensive chronotype dataset encompassing 71,016 209 participants from the EstBB. The large age span of our sample enabled us to investigate 210 opposite refractive errors and thus to dissect factors predisposing to eye growth abnormalities 211 in general and factors influencing the directionality of eye growth. One of the most striking 212 findings is the robust bidirectional association of chronotype with refractive errors, where 213 individuals with a later chronotype showed increased odds of having myopia, aligning with 214 previous reports employing smaller samples<sup>22,27,28</sup>. In contrast, an earlier chronotype was linked to a higher likelihood of hyperopia. It should be noted, however, that refractive 215 development occurs primarily in childhood and adolescence<sup>2</sup>, while chronotype was assessed 216 217 during adulthood in our study sample. Nevertheless, chronotype has a considerable genetic basis, reaching a heritability of 12-20%<sup>44-46</sup>, with some of the most significant genetic hits 218

being genes regulating the circadian clock on a molecular level<sup>44–46</sup>, such as period 1, 2 and 219 220 3 (PER1, PER2, PER3), cryptochrome 1 (CRY1) and ARNTL. In twin studies, self-reported 221 morningness-eveningness has been shown to reach an inheritance of 44% in adolescent twins 222 and 47% in twins in their mid-40s<sup>47</sup>. Furthermore, variations in molecular circadian clock genes 223 underlie extreme sleep-wake cycle phenotypes, for example, the familial advanced sleep-224 phase syndrome, characterised by a persistent 3-4-hour advanced sleep schedule compared to desired times<sup>48</sup>, is caused by mutations in two core molecular clock genes, *PER2*<sup>49</sup> and 225 casein kinase 1 delta  $(CSNK1D)^{50}$ . Collectively, these data suggest that chronotype reflects 226 227 an intrinsic property rather than a transient state of an individual's sleep-wake cycle. We also 228 found that time spent in daylight as an adult was associated with myopia and hyperopia. We 229 hypothesise that although the amount of time spent outdoors in adulthood would not affect 230 refractive development, it may reflect habits ingrained from childhood.

231 This association between chronotype and refractive errors raises multiple hypotheses 232 regarding the biological mechanisms influencing eye growth. First, chronotype may influence 233 the development of refractive errors by predisposing individuals to a factor associated with 234 myopia and hyperopia. For example, late chronotypes might spend less time outdoors, as shown in previous reports<sup>9,51</sup>, which is a well-characterised risk factor for myopia<sup>31–33</sup>. 235 236 Speaking against this hypothesis, we found no correlation between chronotype and time spent 237 outdoors in our study sample (Fig. 1e), and we adjusted our analysis for the reported time 238 spent outdoors. However, these might not have reflected the variables in childhood, as 239 240 could be that having myopia or hyperopia shifts individuals' sleep-wake cycles later and 241 earlier, respectively. The primary brain centres regulating circadian activity are the 242 suprachiasmatic nuclei (SCN), which receive extensive direct input on light levels from the 243 retinas of the eves<sup>52</sup>. It is known that some aspects of retinal signalling are altered in myopia<sup>53</sup>. 244 which could potentially modify the light input reaching the SCN and result in variations in 245 chronotype. Third, the link between chronotype and refractive errors may reflect parallel 246 molecular processes rather than a causal relationship, as the development of the SCN and circadian system is modulated by input from the eyes<sup>52</sup>. Various processes in the eye, 247 including the length of the eye<sup>5</sup>, display a daily rhythm, which is abolished in animals 248 249 developing myopia<sup>6</sup>. If we consider chronotype as a marker for circadian rhythms on a 250 molecular level, it may suggest that genetic variations that lengthen the circadian clock and 251 result in late chronotype may also lead to excessive eye elongation by disrupting the 252 rhythmicity of eye growth. Further genetic studies and investigations in animal models are 253 required to uncover the causality of this finding.

Intriguingly, we witnessed that decreased sleep duration and increased SJL increased 254 255 the odds of myopia and hyperopia. SJL is indicative of the discrepancy between the inner 256 biological clock of an individual and the social clock imposed by society<sup>12</sup>, and it has been

257 associated with several adverse health outcomes, including metabolic disorders, cardiovascular problems, and psychiatric diseases<sup>11</sup>. It can be hypothesised that increased 258 259 SJL may disrupt processes governing eye development. Alternatively, an increased SJL might 260 be desirable-individuals generally accumulate sleep debt over workdays, which is 261 counterbalanced by longer sleep on the weekends<sup>54</sup>. A larger difference between the mid-262 point of sleep on working and free days can thus indicate voluntary sleep extension on the 263 weekends, which can serve to dissipate sleep debt<sup>54</sup>, complicating the interpretation of this 264 finding.

265 Additionally, we provide evidence that some factors protective of myopia may be risk 266 factors for hyperopia. We demonstrate that an increased amount of time in daylight, which is 267 protective of myopia<sup>31–33</sup>, associates with higher odds of hyperopia. Additionally, a higher level 268 of education, which is linked with myopia, decreased the odds of hyperopia. While it has been 269 shown that children with uncorrected hyperopia have worse academic performance<sup>55</sup>, 270 moderate hyperopia has previously not been associated with a lower level of education in 271 adulthood<sup>56</sup>. These findings further suggest that myopia and hyperopia are conditions on the 272 same spectrum, and specific factors affect the conditions in opposing directions. This insight 273 is crucial for further analysis of the factors underlying myopia, highlighting several elements 274 that predispose individuals to refractive errors in general, as well as those influencing their 275 directionality.

276 In addition to investigating circadian rhythms and sleep in refractive errors, we 277 characterise chronotype and sleep parameters in the EstBB. As reported previously, we found that chronotype decreased throughout adulthood, showed differences between sexes<sup>12,36</sup>, and 278 279 SJL also decreased with age<sup>10,12</sup>. As a novel finding, we characterise the sex differences of SJL. Since late chronotype has been associated with increased SJL<sup>12</sup> and men have a later 280 chronotype until around the 50s<sup>12,36</sup>, men have also been hypothesised to display larger SJL<sup>11</sup>. 281 282 Surprisingly, we found that SJL was larger in women from the 30s until late adulthood when 283 SJL became negligible (Fig. 1b, Table 1). These findings indicate that although SJL is 284 influenced by chronotype, these two measures are distinct and characterise specific aspects 285 of the interaction between circadian rhythms and sleep.

286 While providing valuable insights into the relationship between refractive errors, 287 chronotype and sleep, this study is subject to certain limitations that warrant consideration. 288 First, although the sample is representative of the Estonian population<sup>57</sup> and has sufficient 289 statistical power, the ethnic diversity within the EstBB is relatively low (see Table 2). It is known that circadian rhythms are affected by ethnicity<sup>58,59</sup>, and it is, therefore, challenging to 290 291 generalise our findings to non-European populations. Consequently, it is crucial to replicate 292 the results presented here in more diverse and also non-European settings to ascertain their broader applicability and to understand the potential variances in these associations across 293 294 different populations. Second, we defined myopia and hyperopia using data from electronic

295 health records and self-reports, which do not indicate the extent of the refractive errors. It 296 would be insightful to conduct similar analyses with refractive error as a continuous variable 297 to determine whether the extreme chronotypes would also be associated with extreme 298 refractive errors. Such studies would further strengthen the finding of an inverse relationship 299 between chronotype and refractive errors.

300 To unravel this complex interplay between circadian rhythms and refractive errors, 301 further research using a variety of approaches is required. Genetic studies, particularly those 302 leveraging large biobank datasets, could be instrumental in identifying specific genes that 303 contribute to this association. Such genetic insights would enhance our understanding of the 304 molecular mechanisms of eye development and aid in developing targeted therapeutic 305 interventions. Additionally, studies in animal models will be invaluable in dissecting causality 306 and molecular mechanisms that link circadian rhythms with refractive development. Animal 307 models enable the manipulation of genes, molecular pathways, and environmental conditions 308 in a controlled fashion, allowing the detailed study of these interactions. Finally, there is a 309 compelling need for additional observational studies, especially those focusing on critical 310 developmental stages such as childhood and adolescence, to validate and extend the 311 correlations identified in this work. Longitudinal studies tracking individuals over time would 312 be particularly informative, as they could establish temporal relationships and potentially 313 causal links between chronotype, sleep patterns, and refractive development. These 314 investigations should also elucidate the interaction of environmental factors, such as light 315 exposure and lifestyle habits, with genetic predispositions that could provide a more holistic 316 understanding of refractive development. This could lead to more effective prevention 317 strategies tailored to individual risk profiles, incorporating both genetic and environmental 318 considerations.

319

320

#### 321 Methods

322

#### 323 Data in the Estonian Biobank

The Estonian Biobank (EstBB) is a population-based biobank with 210,500 adult participants 324 in the 20<sup>th</sup> December 2022 data freeze<sup>57</sup>, which was used for this study. All biobank 325 participants have signed a broad informed consent form. Information on medical diagnoses is 326 327 obtained through annual linking with the Estonian National Health Insurance Fund and other 328 relevant databases. Diagnoses are coded with the International Classification of Disease 10<sup>th</sup> 329 edition (ICD-10). The majority of the electronic health records have been collected since 330 2004<sup>57</sup>. The activities of the EstBB are regulated by the Human Genes Research Act<sup>60</sup>, which 331 was adopted in 2000 specifically for the operations of EstBB. Individual level data analysis in 332 EstBB was carried out under ethical approval 1.1-12/624 from the Estonian Committee on

333 Bioethics and Human Research (Estonian Ministry of Social Affairs), using data according to 334 release application 3-10/GI/34223 from the EstBB.

335 All EstBB participants have been genotyped at the Core Genotyping Lab of the Institute 336 of Genomics, University of Tartu, using Illumina Global Screening Array v3.0 EST. Samples 337 were genotyped and PLINK format files were created using Illumina GenomeStudio v2.0.4. 338 Individuals were excluded from the analysis if their SNP call-rate was <95%, if they were 339 outliers of the absolute value of heterozygosity (>3 standard deviations from the mean) or if 340 sex defined based on heterozygosity of X chromosome did not match sex in phenotype data $^{61}$ . 341 Genotyped variant positions were in build GRCh37, and genetic principal components analysis (PCA) was performed in PLINK2<sup>62</sup>. Ancestry proportions and ancestry grouping were 342 343 estimated with bigsnpr<sup>63</sup>. For ancestry inference, genotypes were imputed using 1000 344 Genome Project samples (n=2495). The total number of SNPs used for the inference was 345 ~4.54 million. Samples from all ancestries were included in the study.

346

#### 347 Munich Chronotype Questionnaire

The standard questionnaire administered to all EstBB participants contains the Estonian 348 translation<sup>64</sup> of the Munich Chronotype Questionnaire (MCTQ)<sup>9</sup>. The questionnaire asks 349 350 participants about their sleep habits over the past four weeks separately for working and free 351 (non-working) days. Participants were included in the analysis only if they reported not having 352 done any shift work in the past three months and waking up without an alarm clock on free days, as only then is the calculated chronotype value estimating true biological clock<sup>9</sup>. All sleep 353 354 parameters were calculated as per Roenneberg et al. 2003<sup>9</sup>. Briefly, chronotype was defined 355 as the mid-point of sleep on free days adjusted for sleep debt (MSFsc) and reported as local time<sup>9</sup> in 24-hour format. SJL was defined as the absolute difference between one's midpoint 356 357 of sleep on free and working days. Average daily sleep duration was calculated as (sleep 358 duration on a working day \* 5 + sleep duration on a free day \* 2) / 7. Average daily exposure 359 to daylight was calculated as (time in daylight on a working day \* 5 + time in daylight on a free 360 day \* 2) / 7. Replies were filtered for unrealistic and extreme values (see Supplementary Fig. 361 1 for workflow). MCTQ parameters were characterised in participants <80 years at the time of 362 replying to MCTQ.

363

#### 364 Definition of myopia and hyperopia

365 Participants were classified as myopes if they had received the ICD-10 diagnosis of H52.1 366 (myopia) or if they reported having received the diagnosis of myopia; and hyperopes if they 367 had received the diagnosis of H52.0 (hyperopia) or if they reported having received the 368 diagnosis of hyperopia. Self-reported diagnoses constituted 11% and 13% of the total number 369 of diagnoses for myopia and hyperopia, respectively. Self-reported diagnoses were included 370 as in Estonia, people with refractive errors are often followed primarily by optometrists, whose

371 diagnoses are not reflected in the National Electronic Health records. Participants who had 372 both myopia as well as hyperopia were excluded from the analysis (Supplementary Fig. 1). All 373 remaining participants were defined as controls.

374

#### 375 Additional sociodemographic characteristics included in the analyses

376 The highest level of education was self-reported by the participants on a nine-level scale, and 377 these were further combined into three categories as follows: 1) basic education (no primary 378 education, primary education, and basic education); 2) secondary education (secondary 379 education and vocational secondary education); 3) higher education (higher education, 380 applied higher education and advanced academic degree). The education level reported at 381 the time of filling out the MCTQ was used. Daily time spent in daylight was reported by 382 participants as part of the MCTQ separately for weekdays and free days. The average daily 383 time spent in daylight was calculated as follows: (time spent in daylight on a working day \* 5 + time spent in daylight on a free day \* 2) / 7. The season of birth was defined as follows. 384 385 Spring: March, April, May, summer: June, July, August; autumn: September, October, November; winter: December, January, February. Photoperiod categories were defined as per 386 387 Mandel *et al.* 2008<sup>34</sup>. Briefly, the civil twilight hours (period from dawn until dusk) in Tallinn in 388 2022 were downloaded from the US Navy Astronomical Applications Department public 389 repository (available at: https://aa.usno.navy.mil/data/Dur OneYear, accessed August 31, 390 2023). Tallinn was chosen as the reference as it is home to approx. 33% of the Estonian 391 population. The 365 days of the year were divided into four photoperiods so that they would 392 include approximately an equal number of days. Photoperiods were defined as shortest (6 393 hours 3 minutes to 8 hours 23 minutes of daylight; November 6 – February 1, 90 days), 394 followed by short (8 hours 25 minutes to 12 hours 21 minutes of daylight; February 2 – March 395 21 and September 21 – Nov 5, 91 days), long photoperiod (12 hours 23 minutes to 16 hours 396 18 minutes of daylight; March 22 – May 5 and August 6 – September 20, 92 days) and longest 397 photoperiod (16 hours 18 minutes to 18 hours and 39 minutes of daylight, May 6 – August 5, 398 92 days). Age at filling out the MCTQ was used as the age reported in the article. Age was 399 included as a covariate in the logistic regression analyses with one-month precision. MCTQ 400 parameters were characterised for participants aged ≤80 years to allow for comparison with previously published datasets<sup>12,65</sup>. Logistic regression analysis was performed in participants 401 402 aged ≤70 years old as age-related diseases, e.g. ocular and neurological conditions and eye 403 diseases, can influence one's sleep patterns and circadian rhythms<sup>41,42</sup>.

#### 405 Statistical analysis

406 Descriptive statistics (mean and standard deviation; median and interguartile range; number 407 and proportion) were used to characterise the study population and refractive error subgroups. 408 Variables characterised included age, sex, education, birth season, photoperiod at birth, 409 ethnicity, chronotype, SJL, sleep duration (SDweek) and daylight exposure.

410 Chronotype, SJL and average sleep duration in a day were characterised by sex 411 across age groups. The study population was divided into 12 age groups, the youngest aged 412 18-25 years, followed by 5-year intervals up to age 80. For variables with normal distribution 413 (MSFsc and SDweek), a linear regression model including an interaction term between sex 414 and age group was fitted. The emmeans R package version 1.8.9<sup>66</sup> was used further to 415 compare MSFsc and SDweek between sexes within each age group and to estimate marginal 416 means with 95% confidence intervals. Differences between sexes were analysed with two-417 tailed t-tests followed by the Bonferroni method to control for the family-wise error rate. To 418 estimate medians and 95% confidence intervals of medians of SJL across sexes and age 419 groups, bootstrapping using the boot R package version 1.3-28.1<sup>67</sup> was employed. A quantile regression model was fitted using the guantreg R package version 5.96<sup>68</sup> including an 420 421 interaction term between sex and age group. Differences in median values between the sexes 422 within each age group were assessed using the p values associated with the interaction terms 423 between sex and each age group in the quantile regression model. Correlations between 424 chronotype, SJL, average sleep duration and time spent in daylight were estimated using 425 Pearson and Spearman correlation for normally and non-normally distributed variables, 426 respectively.

427 To assess the association between a set of predictors and myopia/hyperopia, we fitted 428 separate logistic regression models with myopia or hyperopia status as the dependent 429 variable, including participants classified as myopes or hyperopes as cases, respectively and 430 participants with no refractive error as controls. For univariate analysis, a separate model 431 adjusted for age, age squared, and sex was fitted for each predictor (chronotype, SJL, average 432 sleep duration, time spent in daylight, education level, season at birth and photoperiod at 433 birth). For multivariate analyses, all the aforementioned predictors were simultaneously 434 analysed, and the models were additionally adjusted for the first ten genetic principal 435 components. Multicollinearity was tested by calculating the variance inflation factor for independent variables in regression models, and no multicollinearity was detected between 436 437 the variables of interest. As a sensitivity analysis, the same multivariate analyses were 438 pursued in a subsample with age >45 years.

All analyses were carried out and visualised using R 4.3.1<sup>69</sup> and RStudio 439 2023.06.1+524<sup>70</sup>. A p value of <0.05 was considered statistically significant. 440

### 442 Inclusion & Ethics

443 All biobank participants have signed a broad informed consent form, and information on ICD-444 10 diagnosis codes is obtained via regular linking with the National Health Insurance Fund 445 and other relevant databases, with the majority of the electronic health records having been 446 collected since 2004<sup>57</sup>. The activities of the EstBB are regulated by the Human Genes 447 Research Act<sup>60</sup>, which was adopted in 2000 specifically for the operations of EstBB. Individual 448 level data analysis in EstBB was carried out under ethical approval 1.1-12/624 from the 449 Estonian Committee on Bioethics and Human Research (Estonian Ministry of Social Affairs), 450 using data according to release application 3-10/GI/34223 from the EstBB.

451

## 452 Acknowledgements

This research was supported by the European Union through Horizon 2020 research and innovation programme under grants no 810645 and 894987, through the European Regional Development Fund project no. MOBEC008, and the Estonian Research Council grants PRG1291 and PRG1414. Data analysis was carried out in part in the High-Performance Computing Centre of the University of Tartu. We acknowledge the Estonian Biobank Research Team (Andres Metspalu, Reedik Mägi, Mari Nelis and Georgi Hudjashov). We would like to thank Priit Palta for constructive feedback on the manuscript.

460

## 461 Author contributions

462 T.P. and E.A. designed the study, T.P., M.T.-L. and K.-L.K. performed the MCTQ calculations 463 and data cleaning. T.P and N.T. performed the sample characterisation and statistical 464 analyses. U.A., E.A. and K.R conducted the genetic analyses for genetic principal components 465 and ancestry. E.A and T.E supervised the study. T.P. and E.A. wrote the first draft of the 466 manuscript. All authors critically reviewed the manuscript. E.A. and T.E. contributed equally to 467 this work.

468

### 469 **Competing interests**

- 470 The authors declare that they have no competing interests.
- 471

### 472 Data availability

473 Pseudonymised genotype and phenotype data are available from the Estonian Biobank

- 474 (https://genomics.ut.ee/en/content/estonian-biobank) upon request.
- 475

### 476 Code availability

477 Analyses used are described in the Methods section of the manuscript.

Table 1. Characterisation of chronotype, social jet lag and sleep duration by sex and age group in a population aged between 18 and 80 years

<sup>1</sup> Generalised linear model was fitted with two independent variables, age group and sex, along with their interaction, and the dependent variable, MSFsc or SDweek. Post-hoc comparisons were conducted using the emmeans R package. Estimated marginal means (EMMs) and their 95% CI were calculated for each combination of sex and age group. The significance of differences between sexes within each age group was assessed using two-tailed t-tests and the Bonferroni method to adjust for multiple comparisons.

<sup>2</sup> Quantile regression model was fitted with two independent variables, age group and sex, along with their interaction, and the dependent variable SJL. Differences in median values between the sexes within each age group were assessed using the *p* values associated with the interaction terms between sex and each age group in the quantile regression model. *p* values < 0.05 are indicated in bold. Medians and 95% CI for medians were estimated using bootstrapping with the boot R package.

CI – confidence interval, EMM – estimated marginal means, MSFsc – mid-point of sleep on free days adjusted for sleep debt, SD – standard deviation, SDweek – weekly average sleep duration, SJL – social jet lag.

### Table 2. Characteristics of the study population included in the logistic regression analysis

Characteristic	<b>Overall</b> N = 71,016 (100%)	<b>None Myopia</b> N = 41,832 (58.9%) N = 18,516 (26.7		Hyperopia N = 10,668 (15.0%)	p value <sup>1</sup>

Observations	60,348			52,500			

Odds ratios were obtained from two multivariable logistic regression models with myopia or hyperopia status as the dependent variable, including participants classified as myopes or hyperopes as cases, respectively, and participants with no refractive error as controls. Both models used MSFsc, SJL, SDweek, LEweek, education, birth season, and photoperiod at birth as predictors, and were adjusted for age, age squared, sex and first ten genetic principal components. p values < 0.05 are highlighted in bold.

LEweek -average daily exposure to daylight, MSFsc - mid-point of sleep on free days adjusted for sleep debt, SDweek weekly average sleep duration, SJL - social jet lag, CI - confidence interval.
