Abstract (249/250) 33

- 34
- Background: Gay, bisexual, and other men who have sex with men (GBMSM) face a 35
- disproportionate burden of sexually transmitted infections and are eligible for targeted 36
- vaccinations for hepatitis A (HAV), hepatitis B (HBV), human papilloma virus (HPV) and 37
- mpox. This study examines the sociodemographic characteristics, sexual behaviours, and 38
- sexual healthcare service (SHS) use associated with vaccination uptake. 39
- Methods: We undertook analyses of RiiSH-Mpox an online, community-based survey with 40
- $\begin{array}{l} \textbf{Mote:} This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.\\ \textbf{GBMSM} recruited via social media and dating apps. We calculated vaccination uptake (<math>\geq 1$) 41

- 42 dose) among eligible GBMSM. Bivariate and multivariable logistic regression was performed
- 43 to identify factors independently associated with vaccination uptake among eligible
- 44 participants.
- 45 **Results**: Reported uptake in eligible GBMSM was around two-thirds for each of the
- 46 vaccinations considered: mpox 69% (95% confidence interval (CI): 66%-72%), HAV 68%
- 47 (CI:65%-70%), HBV 72% (CI:69%-74%) and HPV 65% (CI:61%-68%). Vaccination course
- 48 completion (receiving all recommended doses) ranged from 75% (HBV) to 89% (HAV)
- 49 among eligible GBMSM. Individuals who represented missed opportunities for vaccination
- 50 ranged from 22-30% of eligible SHS attendees. Younger participants, individuals identifying
- as bisexual, reporting lower educational qualifications, or being unemployed reported lower
- 52 uptake across GBMSM-selective vaccinations. Individuals who reported greater levels of
- 53 sexual behaviour and recent SHS use were more likely to report vaccinations.
- 54 **Conclusion**: Eligible participants reported high uptake of vaccinations; however, uptake was
- 55 lower amongst young GBMSM and self-identifying bisexual men. Awareness of groups with
- 56 lower vaccination uptake will help inform practice, delivery strategies and health promotion,
- 57 to improve the reach and impact of vaccinations amongst GBMSM.

58 **Contributions:**

- 59 DP, RW, KF, CHM, JS, HM reviewed and updated the survey instrument. Survey
- 60 implementation, data collection and data management were carried out by RW and DO. GB,
- 61 CM, DO, HM curated secondary analysis plan with review and contributions from KF, MC,
- 52 JS, RS, SM. GB conducted analysis and completed the first manuscript draft. All authors
- 63 contributed to successive drafts and reviewed and approved the final manuscript.

64 **Ethics statement:**

65 Ethical approval of this study was provided by the UKHSA Research and Ethics Governance

66 Group (REGG; ref: R&D 524). Online informed consent was received from all participants

and all methods were performed in accordance with guidelines and regulations set by the

68 UKHSA REGG.

69 **Competing interests:**

70 Authors have no competing interests to declare.

71 Data availability statement:

- 72 The data that support the findings of this study are available upon reasonable request from the
- 73 UK Health Security Agency (UKHSA). Requests can be directed to Dr Hamish Mohammed
- 74 (<u>hamish.mohammed@ukhsa.gov.uk</u>).

75 Funding:

This study did not receive any funding and was conducted as part of the UKHSA publichealth response to mpox.

93 Introduction

- 94
- 95

Gay, bisexual, and other men who have sex with men (GBMSM) continue to be

97 disproportionately affected by sexually transmitted infections (STIs) and viral hepatitides

98 (VHs) both globally¹ and in the UK². To reduce individual and public health impacts of these

99 infections in the UK, several vaccines are recommended for $GBMSM^{3-6}$, this includes HPV

100 (human papilloma virus), Hepatitis A (HAV) and Hepatitis B (HBV), which can be spread

- 101 through sexual contact amongst other means⁷.
- 102

103 UK immunisation policy and clinical advice is outlined in The Green Book: Immunisation

against Infectious Disease, a compilation of immunisation evidence, procedures, and

105 guidance for vaccine preventable diseases⁸. The UK currently recommends opportunistic

immunisation against HAV and HBV to all GBMSM, particularly those who change sexual

107 partners frequently^{3,7}. HPV vaccination in the UK was initially introduced for girls aged 12-

108 13 to prevent cervical cancer^{9,} but was recommended for GBMSM up to and including age 45

from 2016 and for adolescent boys from 2019^5 . Most recently, GBMSM-selective

110 vaccination programmes have been brought into focus through the rapid introduction of

vaccination for mpox in response to the 2022 mpox outbreak which particularly affected this
 group¹⁰.

113

114 There is limited literature examining STI/VH vaccination uptake and acceptability among

115 GBMSM. While a pilot study among UK GBMSM found that 89% would willingly receive

the HPV vaccine upon recommendation¹¹, reported uptake of the HPV vaccine is only 34%

among GBMSM attending sexual health services (SHS) in England (uptake has also likely

decreased due to the impact of COVID-19 on SHS in-person service delivery)¹². Data on

119 HAV/HBV vaccination uptake among GBMSM in England is also very limited.

120

121 To understand STI/VH vaccination uptake inequalities, we investigated the factors associated

with uptake of recommended STI/VH vaccines in the UK among a community-sample ofGBMSM.

124

125 Methods

126

127 Study design and Data collection

128

129 This study used data collected by the 2022 round of the 'Reducing inequalities in Sexual

130 Health during the mpox outbreak' (RiiSH-mpox) survey, part of a series of cross-sectional

131 community-based surveys first run in 2017^{13} . The RiiSH surveys focus on health and

132 wellbeing, sexual risk behaviours, and use of SHS amongst GBMSM, and have been used to

improve understanding of the factors underlying STI trends among GBMSM in the $UK^{14,15}$.

134 RiiSH-Mpox included questions on these core topics as well as mpox vaccine uptake during

the 2022 mpox outbreak. Details of the RiiSH-Mpox methodology have been previously
 reported¹⁵.

137

The RiiSH-Mpox survey was deployed from 24 November-19 December 2022 and included
participants that were aged ≥16 years, a UK resident, individuals self-identifying as men

- 140 (cisgender/transgender), transgender women, or gender-diverse individuals assigned male at
- 141 birth (gender was overlooked in this analysis, 99% self-identified as a cis-male), and
- 142 individuals who self-reported having had sex with a man in the last year. Participants were
- recruited through advertisements on social media (Facebook, Instagram, Twitter [now X])
- and through the geospatial networking application ('dating app') Grindr. Online consent was
- 145 provided by all participants. Lookback periods for healthcare-related factors and sexual risk
- behaviours varied from reporting since August 2022 (i.e. last 3-4 months), to ever.
- 147
- 148 Due to relatively low numbers of participants who did not self-report being white or
- 149 gay/homosexual these variables were dichotomised as white or any other ethnic group, and
- 150 either gay/homosexual or bisexual, respectively.
- 151
- 152 Data analysis
- 153

154 Vaccination uptake

155

156 To measure uptake and completion levels of vaccination, percentages and 95% confidence

157 intervals (CI) (Clopper-Pearson) were calculated. Uptake was defined as receiving at least

- 158 one dose of a vaccine and completion as receiving all recommended doses as outlined by the
- 159 UK vaccination guidance at the time of the survey (2 doses of HAV, HPV or mpox vaccine
- and 3 HBV vaccine doses).
- 161
- 162 Uptake amongst all participants and eligible GBMSM for each vaccine was calculated.
- 163 Reflecting UK vaccination guidance³, we considered all GBMSM as eligible for HAV and
- 164 HBV vaccination. HPV vaccination eligibility was considered in GBMSM reporting SHS
- 165 attendance who were up to and including age 45, given opportunistic vaccination
- 166 recommendations across SHS. In line with mpox vaccination guidance^{6,10}, mpox vaccination
- eligibility was considered in those reporting: ≥ 10 physical male sex partners, meeting
- 168 partners in public sex environments (Sex on premise venues (SOP), cruising grounds or sex
- 169 parties), having a positive STI test, report of HIV-PrEP or use of chemsex-associated
- 170 recreational drugs (crystal methamphetamine, mephedrone or gamma-
- 171 hydroxybutyrate/gamma-butyrolactone). SHS attendance was not considered as part of
- 172 eligibility for HAV, HBV and mpox vaccination given vaccination availability outside of
- 173 SHS (e.g. mpox vaccination outreach, general practice and travel clinic availability for VH
- 174 vaccination).
- 175
- To measure the association between uptake of different vaccine types, logistic regression was used to generate the unadjusted (uOR) and adjusted odds ratio (aOR) of receiving at least one

178	dose of a respective vaccine versus also receiving at least one dose of another vaccine
179	(vaccines were compared sequentially, in a pairwise manner). For adjusted analyses, age-
180	group and sexual orientation were considered a priori, and additional factors were added in a
181	forwards stepwise manner based on significant bivariate association and evidence from
182	previous literature ^{11,16–19} .
183	
184	Missed vaccination opportunities in those attending sexual health services
185	
186	GBMSM who reported ever having attended an SHS and who met respective proxy
187	vaccination eligibility were considered missed opportunities for vaccination if no vaccination
188	history was reported.
189	
190	Factors associated with vaccination uptake
191	
192	Among all participants irrespective of previous SHS attendance (except those over age 45/
193	those who had not previously attended SHS for HPV vaccination), Pearson's chi-squared test
194	and bivariate logistic regression was used to examine association between sociodemographic,
195	sexual behaviour and health-related factors with vaccination uptake for the HAV, HBV and
196	HPV vaccines, respectively. Analysis of factors associated with vaccination for mpox uptake
197	has been previously reported ¹⁵ so was not examined in this analysis. Multivariable adjustment
198	for significant sociodemographic, sexual behaviour and health-related factors, as per methods
199	described above, was applied.
200	
201	All analysis was completed using Stata V17.0 (College Station, TX, USA) and all p values
202	below 5% were deemed statistically significant.
203	
204	

Results 205

Altogether, 1435 individuals engaged with RiiSH-Mpox survey, of whom 1333 met the 206 inclusion criteria. Of these, half were aged over 45 years, 37% were 30-44 and the remaining 207 208 13% were 16-29. Almost all self-identified as gay/homosexual (89%) and were of white

ethnicity (92%). Most lived in England (86%), 81% were employed, 37% reported at least 209

- degree level education, with 48% responding that they were financially comfortable. See 210
- 211 Appendix A for sample characteristics.

212

213 **Vaccination Uptake**

- 214
- 215 Among all participants, 97% self-reported receiving at least one dose of any STI/VH
- 216 vaccination. HAV vaccination uptake was 68% (CI:65%-70%, 903/1333) and HBV
- vaccination was 72% (CI:69%-74, 954/1333). Mpox vaccination uptake among eligible 217
- participants was 69% (CI:66%-72%, 601/875), or 52% (CI:49%-55%, 692/1,333) among all 218

medRxiv preprint doi: https://doi.org/10.1101/2024.03.08.24303981; this version posted March 10, 2024. The copyright holder for this preprint (which was not certified by peer review) is the author/funder, who has granted medRxiv a license to display the preprint in

perpetuity. All rights reserved. No reuse allowed without permission.

GBMSM. In those under age 45 who had ever attended a SHS, HPV vaccination was 73% 219 (CI:69%-76%, 417/574), or 42% (CI:39%-45%, 562/1333) among all participants. 220 221 222 Receiving one vaccine type was uniformly associated with receiving at least one other 223 (Appendix B). The highest association was found between the HAV and HBV vaccines, 224 individuals who had received one were 12 times more likely to have received at least one 225 dose of the other (aOR:11.98, CI: 9.01-15.92). 226 **Vaccine Completion** 227 228 229 HAV vaccination had the highest completion level amongst participants with 89% (CI:87%-230 91%, 807/903) of those that had received at least one dose completing the course. Among 231 individuals that initiated HBV vaccination, 75% completed the course (CI:72%-77%, 712/954). Of those that had initiated HPV vaccination 84% (CI:80%-88%, 350/417) had 232 233 completed the course and 42% (CI:38%-45%, 288/692) of those that had initiated vaccination 234 for mpox completed the course. 235 236 Missed vaccination opportunities in those attending sexual health services 237 238 Missed vaccination opportunities among GBMSM who ever reported SHS attendance history 239 were considered 27% (CI:24-29%) for HAV vaccination, 22% (CI:20-25%) for HBV vaccination, 27% (CI: 26-33%) for HPV vaccination, and 30% (CI: 26-33%) for mpox 240 241 vaccination. 242 Factors associated with vaccination uptake 243 244 245 Hepatitis A Vaccination uptake 246 There was a bivariate association between HAV uptake and sexual orientation, educational 247 248 level, and employment status, see Table 2. There were significantly lower odds of HAV 249 vaccination amongst those self-reporting as bisexual (aOR:0.56, (CI:0.4-0.8) vs gay/homosexual), having an education that was below degree-level (aOR:0.7, (CI:0.55-0.9)) 250 251 and being unemployed (aOR:0.69, (CI:0.52-0.92)). There was no evidence of an independent 252 association existing between HAV vaccination uptake and age, however uptake was lower in both the 16-29 age group (aOR:0.54, (CI:0.37-0.78)) and the over 45 age group (aOR:0.74, 253 254 (CI:0.57-0.97)). 255 256 Sexual behaviours associated with HAV vaccination uptake included self-reported usage of 257 chemsex-related recreational drugs in the previous year (aOR:1.87, (CI:1.16-3.02)), reporting ten or more male physical sex partners (aOR:1.85, (CI:1.4-2.44)), reporting attendance at 258 SOP venues (aOR:1.58, (CI:1.22-2.05)), self-reporting ≥ 10 condomless anal sex (CAS) 259 260 partners (aOR:1.44, (CI:1.12-1.86)) (all since Aug 2022). Health related factors associated 261 with HAV vaccination uptake included self-reporting being a person living with HIV

(PLWHIV) (aOR:2, (CI:1.38-2.88)), receiving a positive STI test in the past year (aOR:1.95, 262 (CI:1.29-2.96)), visiting a SHS in the past year, (aOR:4.31, (CI:3.36-5.54)), STI test in the 263 past year (aOR:3.25, (CI:2.53-4.18)) and reporting usage of HIV-PrEP since December 2021 264 265 (aOR:3.15, (CI:2.43-4.07)). 266

267 Hepatitis B Vaccination uptake.

268

269 There was a bivariate association between HBV uptake and sexual orientation, educational qualifications, and employment status, see Table 3. There were lower odds of HBV 270

271 vaccination uptake in those self-reporting as bisexual (aOR:0.57, (CI:0.39-0.82) vs

272 gay/homosexual), having an education that was below degree-level (aOR:0.59, (CI:0.46-

0.76)) and being unemployed (aOR:0.71, (CI:0.53-0.96)). There was no evidence of an 273

274 independent association existing between HBV vaccination uptake and age however uptake

275 was lower in both the 16-29 age group (aOR:0.44, (CI:0.3-0.65)) and the over 45 age group 276 (aOR:0.53, (CI:0.4-0.7)).

277

278 Sexual behaviours associated with uptake included reported usage of chemsex-related 279 recreational drugs in the previous year (aOR:1.75, (CI:1.06-2.88)), reporting ten or more 280 physical male sex partners (aOR:1.89, (CI:1.41-2.53)) reporting attendance at SOP venues 281 (aOR:1.51, (CI:1.15-1.99)), self-reporting ≥10 CAS partners (aOR:1.77, (CI:1.37-2.29)) (all 282 since Aug 2022). There were associations with reporting being a PLWHIV (aOR:1.84, (CI:1.26-2.68)), receiving a positive STI test in the past year (aOR:3.17, (CI:1.9-5.29)), 283 visiting a SHS in the past year, (aOR:5.33, (CI:4.1-6.93)), having an STI test in the past year 284 285 (aOR:4.29, (CI:3.31-5.58)) and reporting usage of HIV-PrEP since Dec 2021 (aOR:4.68, (CI:3.51-6.26)).

- 286
- 287 288

289 **HPV** vaccination uptake

290

291 Among eligible individuals the only sociodemographic factors found to have an association 292 with HPV vaccination uptake were being in the 16-29 (younger) age-category (aOR:0.62, (CI:0.43-0.89 vs those aged 30-44)) and having an education below degree-level (aOR:0.55, 293 294 (CI:0.39-0.78)), see Table 4.

295

296 The sexual behaviours that were associated with HPV vaccination uptake include usage of 297 chemsex-related drugs in the previous year (aOR:1.92, (CI:1.01-3.63)), reporting ten or more 298 physical male sex partners (aOR:3.85, (CI:1.77-8.37)) reporting attendance at SOP venues 299 (aOR:1.84, (CI:1.26-2.67)), self-reporting ≥10 CAS partners (aOR:4.27, (CI:2.38-7.65)) (all 300 since August 2022). There were increased odds of HPV vaccination in a multivariable model 301 amongst those reporting being a PLWHIV (aOR:3.3, (CI:1.7-6.39)), receiving a positive STI test in the past year (aOR:7.77, (CI:3.5-17.28)), visiting a SHS in the past year (aOR:14.3, 302 303 (CI:9.51-21.51)), STI test in the past year (aOR:7.74, (CI:5.14-11.65)) and reporting usage of HIV-PrEP since December 2021 (aOR:4.12, (aOR:8.99, (CI:5.97-13.53)). 304

305 306

307 **Discussion**

Analyses of a large, community-based survey of GBMSM in the UK show that vaccination

- 309 uptake was high but far from universal for all targeted vaccinations, with uptake at around
- two-thirds across each of the STI/VH vaccinations considered. In GBMSM attending SHS,
- approximately a quarter were considered potential missed opportunities for vaccination
- across each vaccine type. There was highly correlated uptake between different vaccines and
- 313 similar sociodemographic, behavioural and SHS use factors were associated with uptake of
- each STI/VH vaccine. This provides an important insight into HAV, HBV and HPV
 vaccination uptake amongst GBMSM for which there is limited uptake data in the UK²¹.
- vaccination uptake amongst GBMSM for which there is limited uptake data in the UK^{21} .
- **316** The sociodemographic factors identified in this study found to commonly be associated with
- lower vaccination uptake were younger age, self-identifying as bisexual, and markers of
- 318 lower financial or social capital such as an education below degree-level or being
- 319 unemployed. Vaccination uptake was higher amongst those reporting sexual behaviour which
- 320 increases risk of STI transmission, and relatedly, in those reporting recent SHS use (greater
- sexual behaviour is often associated with SHS utilisation²⁰); indicating that those who are
- most at need of vaccines are receiving them. This mirrors findings of a previous analysis of
- mpox vaccination uptake¹⁵. Vaccine completion ranged from 42% for mpox to 89% for
- HAV. The lower completion rate for the mpox vaccination is likely due to the recency of
- implementation of the vaccination in response to the outbreak in 2022, as well as the fact that
- **326** the offer of second doses only commenced 2-3 months prior to the survey¹⁰.
- 327 The lower odds of vaccination amongst younger age groups has previously been reported in
- 328 other studies assessing HBV and HPV vaccination^{16,19,21}. Gay self-identification, higher
- 329 levels of education and employment were also consistently found to be linked with higher
- 330 vaccination uptake amongst GBMSM, including both HBV and HPV vaccinations^{16,18,21}.
- **331** Young people and bisexual/straight-identifying GBMSM have been identified as groups that
- have a higher sexual risk and a lower SHS engagement²²⁻²⁴. Promotion focused on bisexual
- men is important to reduce the burden of these vaccine preventable STI/VHs amongst
- ${\rm 334} \qquad {\rm GBMSM, \ but \ also \ potentially \ amongst \ women^{25}}.$
- **335** There is also a consistent association between higher vaccination uptake and SHS usage
- 336 (although HAV/HBV vaccines are also administered outside of SHS). Previous research has
- found that GBMSM are not actively seeking out vaccines such as the HPV vaccine^{11,17} and
- that vaccination for HPV is reliant on recommendation by $clinicians^{26,27}$. It follows that to
- **339** become aware of, and to be identified as a candidate for vaccination, they must be attending
- 340 SHSs, (HPV vaccination is targeted to GBMSM attending SHS only). This association has
- been identified previously with one study finding that 90.9% of GBMSM reporting HPV
- 342 vaccination had attended a SHS in the previous year²⁸ (86% in this sample).

343

Those with markers of lower financial or social capital reported lower vaccination uptake, 344 indicating that health inequalities faced by GBMSM are exacerbated amongst those who 345 already experience inequity. The effects of marginalisation may be compounded, and this 346 347 requires an intersectional approach to understanding these groups and how to target them 348 effectively. Understanding their behaviour and whether they require changes in policy and tailored interventions to increase their engagement with SHS, and subsequently uptake of 349 350 STI/VH vaccinations, is needed. This could be through health-promotion messaging such as community outreach programmes and media-based advertisements to reach those who may 351 not normally access SHS. One means may be through encouraging online SHS²⁹ to identify 352 potential vaccination candidates, but this does require online services that are well-integrated 353 with physical SHS and have good signposting for GBMSM, as vaccination requires 354 355 attendance at a physical venue.

- Vaccine completion is also incredibly important to confer the maximum protection against 356
- 357 infection, amongst this sample many of those that initiated vaccination completed the course
- of vaccination. One previous study assessing incomplete vaccination amongst GBMSM in 358
- England found that the most common reason for not receiving additional vaccine doses was 359
- because they were unaware when their next dose was due²⁶. This indicates that vaccine 360
- completion requires additional or alternative promotion to encourage that those who receive 361
- their initial dose will continue to receive additional vaccine doses. 362
- 363 This study has limitations due to the cross-sectional methodology used. For example, there
- may have been recall error as vaccination was self-reported. Also, participants' behaviours 364
- may have changed, and chronology of vaccination relative to behaviour cannot be ascertained 365
- (except vaccination for mpox which only became established June 2022¹⁰). There may also 366
- 367 be a degree of misclassification bias by retrospectively applying eligibility criteria to
- 368 participants as their behaviours may have changed over time.
- Due to the questions regarding vaccination which fell into the 'ever' lookback period, it is 369
- 370 impossible to know when vaccination occurred, which could explain high association
- 371 between HAV and HBV vaccination due to combined packaging of the HAV and HBV
- 372 vaccination or administration of the combined (HAV/HBV) Twinrix vaccine.
- 373 There are also limitations based on the participants' demographics with lower response
- numbers from young people and people who did not self-describe as white. This necessitated 374 dichotomising variables, limiting the quality of these findings for minority groups who also 375
- have an increased burden of STIs^{2,30,31}, using dichotomised measures limits this study's 376
- ability to assess inequalities in vaccine access by ethnicity or gender identity. There is also 377
- 378 potential participation bias, for example the sample appears to be more health conscious than
- the general GBMSM population. For instance, HPV vaccine uptake within the eligible 379
- sample was 65% compared to 34% of GBMSM nationally¹². This sample also excludes 380
- GBMSM not using the applications that this survey was advertised on. However, unlike 381

- previous studies^{28,32} which often focus on those attending SHS, the target population for this
 study was the GBMSM community more broadly.
- 384 Improving uptake is dependent on understanding barriers faced by GBMSM which limit
- vaccination uptake. Within the UK, awareness of factors affecting uptake (especially as the
- 386 JCVI has advised routine implementation of opportunistic vaccination for mpox³³ and
- 387 gonorrhoea [the latter using 4CMenB vaccination³⁴]), will help inform practice and health
- **388** promotion that aligns with NHS³⁵ and UKHSA³⁶ health equity goals. In an international
- 389 context, these results could raise awareness of potential limitations in vaccination uptake due
- **390** to service provision differences and sociodemographic factors in equivalent and future
- **391** GBMSM-selective vaccination programmes.
