18

19 **ABSTRACT:**

20 Objectives: Medical research in Syria faced significant limitations due to inadequate human and
21 financial resources, exacerbated by the ongoing war. Until recently, the curriculum did not
22 incorporate sufficient training on research skills. Consequently, extracurricular workshops were
23 initiated or utilized nationwide to acquire research-related expertise, aiming to bolster research
24 output. This study aims to characterize and evaluate these training endeavors concerning
25 research-related knowledge, attitudes, barriers, as well as research productivity.

26 Methods: This case-control study encompassed all training initiatives in Syria from 2011 to 2020,
27 both on-site and online. Participants consisted of early career healthcare professionals affiliated
28 with all Syrian universities and were recruited into four equal groups based on the quantity of
29 research projects they undertook and published. Our participants reported and assessed
30 individual extracurricular workshops regarding their gained knowledge, attitudes, and practical
31 skills. These initiatives were compared to curricular training and practical peer-led support
32 regarding these outcomes.

33 Results: The study included 53 on-site and 30 online workshops, displaying diverse distributions
34 and features. Attendance of extracurricular workshops correlated with participants' knowledge,
35 attitudes, and research productivity ($p < 0.001$). The most effective interventions were massive
36 open online courses and workshops lasting over 12 hours. Extracurricular workshops and peer-
37 led support has comparable effectiveness and associated with higher knowledge, attitudes, and
38 practical skills of their beneficiaries in comparison to curricular training (adjusted $p < 0.05$). Lastly,
39 peer trainers in these workshops exhibited more publications and higher levels of knowledge and
40 attitude than the rest of the sample (adjusted $p < 0.05$).

41 Conclusions: Overall, extracurricular interventions and peer support demonstrated their
42 superiority over curricular training. Despite the varied nature of these workshops and the absence
43 of institutional organization, these approaches exhibited significant potential in enhancing
44 research-related knowledge, promoting positive attitudes, and augmenting research productivity
45 in resource-constrained settings such as Syria.

49

50 **INTRODUCTION:**

51 Research in Syria faced many challenges before the war, including limited research capacities
52 and financial support, which led to poor quantity and quality of research output (1,2). The situation
53 was exaggerated during the Syrian armed conflict, which severely devastated the medical and
54 educational infrastructure and forced the majority of the medical personnel to flee the country
55 (3,4). Consequently, the remaining physicians had to deal with a flood of cases related and
56 unrelated to war (5). leaving them too little motivation and time to improve their academic skills
57 and conduct scientific research (6). In addition, the war also impacted the psychological wellbeing
58 of healthcare professionals and workplace violence exacerbated the incidence of burn-out
59 syndrome among them, which put them under constant pressure and depleted their mental health,
60 competence, productivity, and work satisfaction (7,8). Moreover, the lack of research
61 opportunities, as well as the poor training and mentoring became more prominent as the country

62 was left with a scarcity of expertise in this field (9,10). It is worth mentioning that evidence-based
63 medicine (EBM) was not formally part of the curriculum in Syrian medical faculties until 2016
64 (9,11). Hence, the pressing and yet unaddressed requirement remained the implementation of
65 accessible, cost-effective, and sustainable training methodologies aimed at augmenting research-
66 related competencies among Syrian medical professionals (12).

67 On the other hand, significant efforts started to target this paucity at the different Syrian medical
68 schools and they were mainly led by small teams of residents and medical students (9). Local
69 peer-led workshops arose as an alternative cheap method to assist medical students and
70 residents in this field (13). Initially, these teams leveraged online international resources to
71 enhance their research-related knowledge and skills. This initiative empowered them to
72 autonomously strategize, execute, and publish research studies. Subsequently, they effectively
73 orchestrated workshops across Syria, imparting fundamental principles of medical research to
74 their peers, thereby sharing the expertise and experiences acquired. On the institutional level,
75 these efforts were aided by associations gathering Syrian medical professionals practicing abroad
76 such as the Syrian American Medical Society, who also coordinated advanced online courses
77 regarding EBM and academic writing (14,15). Recently, more basic online workshops were
78 delivered by peers performing research careers abroad (13,16). These online workshops were
79 shown to be as effective as face-to-face workshops on participants' knowledge (14), but offered
80 valuable advantages like affordability, flexible accessibility (13), and safety especially in war
81 zones,(15) non-governmental controlled areas (17), and during pandemics (18,19), which made
82 them more favorable in countries with limited resources like Syria. The progress made by Syrian
83 efforts on this front paved the way for Syrian doctors to seek further training from international
84 bodies when provided as massive open online courses (MOOCs) (9,16). For instance, remote-
85 sites were liaised for the comprehensive course “the Introduction to the Principles and Practice of
86 Clinical Research (IPPCR)” provided by the American national institutes of health (NIH) in several
87 Syrian medical faculties and in several years. These steps made it possible to leverage from more

88 formal sources of medical research training even for participants in massively destroyed cities like
89 Aleppo (20).
90 Despite the great efforts spent to achieve all these extracurricular interventions and, when
91 assessed, their proven effectiveness, it is difficult to tell whether they collectively achieved the
92 goals they were aimed at nation-wide. These efforts were not tailored based on comprehensive
93 assessments of the needs and barriers at each phase, location, and field (16). Additionally, they
94 were mostly run by individual or team efforts and lacked cohesive organization and coordination,
95 which hindered both the learning and teaching processes in the long run and challenged any
96 comparison of the efficacy of the different efforts. Consequently, it is still to be proved that the
97 Syrian medical research synthesis significantly improved in quality and quantity due to these
98 initiatives, as most of the research articles published from Syria are still mostly case reports and
99 cross-sectional studies and when they do not end up unpublished, they mostly get published in
100 low impact journals. Therefore, this study aimed to characterize all extracurricular training
101 opportunities utilized by early career Syrian healthcare workers during the first decade of the
102 Syrian war and to assess their impact on attendees' knowledge, attitudes, perceived barriers, as
103 well as their research productivity.

104 **METHODS:**

105 **The identification of extracurricular events targeting medical research:**

106 We identified all interventions targeting research capacity building for Syrian healthcare
107 professionals during the period 2011-2020. This was performed through interviews with trainers
108 and trainees from different academic levels and at all Syrian medical schools. We additionally
109 performed a comprehensive search for event invitations on social media platforms, particularly in
110 groups and channels that target Syrian healthcare professionals and medical and paramedical

111 students around the country. The final list of workshops included all extracurricular in-house
112 training that took place at any of the Syrian medical schools as well as those offered online by
113 international associations or platforms like the American National Institute of Health (NIH) and
114 Coursera. We then extended our interviews to retrospectively define the features of each
115 workshop including its city, year, trainers (professionals or peers), length (approximate number of
116 training hours), size (approximate number of attendees), and focus (research methodology,
117 critical appraisal, academic writing, statistical analysis, systematic reviews, and case reports).
118 Online workshops were also classified into international workshops (i.e., offered by the NIH,
119 Cochrane, Coursera, and Stanford school of Medicine) and Syrian workshops (i.e., offered by the
120 Syrian American Medical Society and Syrian peers abroad). All of the international workshops
121 were delivered in English, while most of the Syrian workshops were presented in Arabic. During
122 data collection, participants also had the possibility to add missing workshops and provide details
123 about their features (e.g., year, city, and duration).

124 **Study design and population:**

125 This study had a case-control design, and its sample population is identical to the one reported
126 in our previous article (21). The recruitment for data collection took place between 05.01.2021
127 and 06.07.2021. Briefly, we communicated the questionnaire individually to all undergraduate
128 students, postgraduate students, residents, and fresh specialists in all Syrian medical and
129 paramedical faculties, who have at least one published article in a peer-reviewed journal. These
130 participants were grouped into two equal arms, the first with one publication and the second with
131 two or more publications. We then recruited two equal control groups, one with participants who
132 contributed to at least one research study (without any publication) and the second with
133 participants who had no previous research contributions. We maintained equal arms at every
134 university and academic level (under- and postgraduates). Syrian specialists and postgraduate
135 students who are currently practicing outside Syria but received their medical training in one of

136 the Syrian universities were not excluded. Participants in their first or second year of
137 undergraduate studies or after more than one year from the end of their specialization were
138 excluded. Further details regarding the ethical approval, data collection, and sample
139 characteristics can be found in our previous article (21); which also reported participants' self-
140 reported research-related knowledge, attitudes, and perceived barriers. Briefly, the ethical
141 approval for this study (30/2020) was obtained from the institutional review board of Damascus
142 University on 19.01.2021. All participants provided their written informed consent for the
143 publication of their anonymous data before their participation.

144

145 **The data collection tool:**

146 The questionnaire developed first asked the participants to identify all the workshops and trainings
147 they took part in by selecting them from a list that contained the name, year, and city of each
148 workshop. In the next step, participants had the possibility to refer to their first, second, and third
149 best workshops in terms of knowledge and skills gained from it. For each of these one to three
150 workshops, participants also assessed the gained knowledge, attitudes, and practical practice on
151 a scale from one to ten, where one stood for poor benefit and ten stood for outstanding benefit.
152 In order to compare these evaluations to other methods of gaining research-related knowledge
153 and skills, we asked the participants to perform the same evaluation for undergraduate and
154 postgraduate curricular research training as well as the practical support they received from peers
155 they worked with on specific research projects. As most of the in-house training was peer-led, we
156 supplemented the questionnaire with a section asking the participants to identify the workshops
157 they participated in training. This information was used afterwards to compare the cohort of these
158 peer trainers to the rest of the sample in terms including knowledge, attitudes, and publications.

159 **Data analysis:**

160 The data was exported to Microsoft Excel 365 version 2011 (year 2020) then analyzed using the
161 Statistical Package for the Social Sciences version 23.0 (SPSS Inc., Chicago, IL, United States).
162 Details about the presentation and statistical analysis of the demographic characteristics,
163 knowledge, attitudes, and barriers including association and correlation tests can be found in the
164 first article (21). In addition, we used different logistic regression tests for models that predicted
165 conducting and publishing research studies as well as number of extracurricular workshops
166 attended and research knowledge and attitudes. For these analyses, regression coefficients and
167 their 95% confidence intervals (CI) were reported as measures of association together with their
168 P values.

169 As most of the participants with multiple publications attended several workshops with various
170 features, we could not link higher research productivity (i.e., number of conducted and published
171 research projects) to specific workshops characteristics. However, to sidestep this obstacle, we
172 grouped participants repeatedly based on the dominant features in the workshops they attended.
173 These groups of participants were then compared to draw conclusions about features responsible
174 more for higher research conduction. For instance, if more than half of the workshops attended
175 by a participant were delivered by peers, he was included in the group of peer-led training and
176 otherwise he would be in the professional-led training group. The same applied when more than
177 half of the training attended by the participant happened online, originated from international
178 organizations, focused on research methodology, took place after 2017, had more than 12 training
179 hours, and recruited more than 40 participants.

180 To limit the number of workshops presented, we excluded those that were attended by less than
181 four participants from our population. To mitigate the possibility of over- or underestimating the
182 rank or the self-assessed benefit from any workshop, we also excluded all workshops that
183 received less than three evaluations (by three participants). For the rest, we allocated points
184 based on the ranking the participants gave to each workshop, where workshops ranked first,

185 second, and third best got three, two, and one points, respectively. To adjust the rankings for the
186 number of attendees, we divided the sum of the points of each workshop by the number of
187 participants in our sample who reported attending this workshop. On the other hand, the gained
188 knowledge, attitudes, and practical practice for each workshop were averaged among entries.

189 An Alpha value of 0.05 was used as a cutoff to determine statistical significance after Bonferroni
190 correction for multiple comparisons. Figures were created using Microsoft Excel 365 version 2011
191 (year 2020) and the Statistical Package for the Social Sciences version 23.0 (SPSS Inc., Chicago,
192 IL, United States), while illustrations were designed using Adobe Illustrator (year 2017) and
193 Microsoft PowerPoint 365 version 2011 (year 2020).

194 **Patient and Public Involvement:**

195 The target audience for this project encompasses medical under- and postgraduates, and this
196 report presents their assessment of the needs and challenges faced towards better research
197 productivity. It is important to note that this project was solely executed by a team comprising
198 these individuals, ensuring that the research directly addresses their needs and interests.

199 **RESULTS:**

200 **The demographics of extracurricular medical research workshops:**

201 Fifty-six in-house workshops that targeted research-related skills were identified during the study
202 period. Our workshops' list additionally included 53 online workshops that were accessible to
203 Syrian healthcare personnel to learn about medical research. Of which, three in-house and 23
204 online workshops were attended by less than four of our participants and were, therefore,
205 excluded from the sample. The few in-house workshops that took place before 2017 were
206 concentrated in Damascus. Afterwards, workshops increased in number and extended to the

207 other two major Syrian medical schools (i.e., Aleppo, and Latakia). In general, the workshops
208 varied in the length of training, number of trainees, and covered topics. However, it can be noted
209 that the most common trained topic of in-house workshops was research methodology (26; 49%),
210 and these workshops had larger size than the ones focusing on other research skills. It is also
211 worth mentioning that the topics covered were not homogenously distributed across the years
212 (e.g., most systematic review workshops happened between 2016 and 2017). Additionally, the
213 majority of in-house workshops (n=45; 85%) were conducted by peers, leaving only seven
214 professional-led workshops, which focused mainly on research methodology. On the other hand,
215 the majority of online workshops were delivered by professionals as MOOCs (n=22; 71%), and
216 they mostly had more than 12 training hours. However, we could still isolate a group of online
217 workshops delivered by Syrians, which were classified into professional-led trainings conducted
218 by the SAMS and peer-led ones (Fig 1).

219

220 Fig 1: Inhouse and online training sources on medical research.

221 Fig 1 legend: Panel a illustrated inhouse trainings while panel b illustrates online sources of
222 training.

223

224 The vast majority of these extracurricular workshops were offered for free and to all under- and
225 postgraduate students as well as specialists. Nevertheless, we found that participants affiliated
226 with the University of Aleppo attended more workshops compared to participants in Damascus
227 and Latakia ($P<0.001$). Furthermore, participants who had better internet connectivity or higher
228 English competence also attended more workshops (S. table 1).

229 **The effectiveness of extracurricular medical research workshops:**

230 After excluding the participants who never attended any research focused extracurricular
231 workshop, we found a significant moderate positive correlation between the number of
232 extracurricular trainings attended and the number of research projects conducted. The number of
233 attended trainings also correlated with the number of publications as well as the total scores of
234 knowledge and attitudes (Fig 2). Moreover, we entered the number of trainings attended together
235 with the total scores of knowledge, attitudes, and barriers, as well as the academic score in a
236 stepwise multiple regression model to predict the number of research projects conducted or
237 published for each participant. This analysis showed that the total knowledge score could
238 independently predict research conduction and publication similarly to our previous article.(21)
239 However, the number of attended extracurricular workshops had an independent added change
240 of 3.6 % to the R2 ($P < 0.001$) specifically in the prediction of number of conducted research studies
241 (S. table 2).

242

243 Fig 2: The impact of the number of workshops attended on research productivity as well as the
244 self-reported knowledge and attitudes towards medical research.

245 Fig 2 Legend: Panel a represents the correlations of conduction (blue) and publication (orange)
246 of research studies, while panel b represents the same for the total knowledge (green) and
247 attitudes (grey) scores. The correlations were estimated based on Spearman's rho methods.
248 Participants who never attended any workshop were excluded ($n=452$ for participation and panel
249 b; $n=364$ for publication).

250

251 **Comparing the features of medical research extracurricular workshops:**

252 MOOCs and workshops that had more than 12 training hours were associated with a higher
253 number of conducted and published studies as well as higher knowledge scores than Syrian-led
254 trainings and shorter workshops, respectively (Fig 3 and Fig 4). These findings were confirmed
255 by stronger correlations between the number of workshops attended with these features on the
256 first side and research productivity, knowledge, and attitudes on the other side (S. table 3).
257 However, as these two features significantly coexist (i.e., most MOOCs had more than 12 training
258 hours), we ran an ordinal logistic regression that confirmed the independent contributions of these
259 two features to the higher research productivity (S. table 4). Furthermore, to isolate the added
260 value of these two features, we added the total knowledge score (i.e., the best predictor of
261 publications) to the same logistic regression. Interestingly, MOOCs lost their independence in
262 predicting the number of publications while the length of the workshops retained its independent
263 effect (S. table 5). On the other hand, participants who attended more professional-led trainings
264 also conducted more research projects and had higher knowledge than those who attended more
265 peer-led trainings. This difference was evident on the correlation analysis but did not show
266 independent contributions to the predictions in the regression analyses.

267

268 Fig 3: The impact of workshops features on research conduction and publication.

269 Fig 3 legend: The bars refer to statistically significant differences in Mann-Whitney U test after
270 Bonferroni correction for multiple comparisons ($P=0.05/8=0.006$); the boxes depict interquartile
271 ranges; the horizontal lines in the boxes present the medians; the X signs show the means; the
272 extending vertical lines illustrate the ranges; and the dots that exceed the line represent outliers.

273

274 Fig 4: The impact of workshops features on participants' knowledge, and attitudes towards
275 research.

276 Fig 4 Legend: The bars refer to statistically significant differences in Mann-Whitney U test after
277 Bonferroni correction for multiple comparisons ($P=0.05/8=0.006$); the boxes depict interquartile
278 ranges; the horizontal lines in the boxes present the medians; the X signs show the means; the
279 extending vertical lines illustrate the ranges; and the dots that exceed the line represent outliers.

280

281 **Participants' evaluation of extracurricular medical research workshops, curricular**
282 **training, and peer support:**

283 Three-hundred-fifty-six participants of our sample indicated the best one to three extracurricular
284 trainings they attended then self-evaluated their gained knowledge, attitudes, and practical skills
285 from each one of them. After excluding the workshops that received less than three individual
286 evaluations, only 54 workshops remained for the analysis. These assessments showed that
287 averaged evaluations of the one to three best extracurricular workshops refer to higher gained
288 knowledge, attitudes, and practical practice than the average of under- and postgraduate official
289 curricular training. It also showed that practical peer support was rated as high as the
290 extracurricular workshops and was also significantly higher than curricular training on the three
291 scales (S. Fig 1). We then ran a correlation analysis between the self-evaluated gained knowledge
292 and attitudes from each of the three training sources with the total knowledge and attitudes scores.
293 The correlations confirmed our findings as they were significant for extra-curricular workshops
294 and peer support but not for the curricular training. Additionally, the estimation of the gained
295 knowledge, attitudes, and practical practice from peer support correlated significantly with
296 research productivity, which did not apply to evaluations regarding curricular training. Meanwhile,

297 the same correlations regarding extracurricular workshops did not survive correction for multiple
298 comparisons (S. table 6).

299 To compare the evaluations of gained knowledge, attitudes, and practical practice among the
300 different features of the workshops, we averaged the assessments of each workshop across
301 participants. Then, we compared the groups of workshops for each gained outcome. However,
302 the only difference that survived the correction for multiple comparisons was the higher practical
303 skills gained from MOOCs when compared to other online workshops (S. Fig 2).

304 **Training on extracurricular medical research workshops:**

305 Seventy-five participants in our sample trained in at least one of the studied peer-led workshops;
306 most of them (n=62, 82.7%) trained in less than three workshops, and 49 of them (65.3%) were
307 affiliated with the University of Aleppo (S. table 7). Participants who trained in workshops reported
308 higher numbers of research projects conducted and published as well as greater knowledge and
309 attitudes compared to those who did not train on any workshop regardless of whether they
310 attended or did not attend any workshop. Trainers also showed higher English competence and
311 attended more workshops compared to those who did not participate in training any workshop
312 (Fig 5). Among these five variables (i.e., research conduction, publication, knowledge, attitudes,
313 and English level), the number of research projects conducted, and knowledge and attitudes
314 scores were isolated as significant independent predictors of the variability between those who
315 trained and did not train on workshops in a binary logistic regression analysis (S. table 8).

316

317 Fig 5: Comparison of the demographic characteristics and research contributions between peer
318 trainers and attendees of research related trainings as well as those who never attended any of
319 these trainings.

320 Fig 5 Legend: The bars represent statistically significant differences in the post-hoc Dunn-
321 Bonferroni-Test pairwise comparison (adjusted $P < 0.05$); the boxes depict interquartile ranges; the
322 horizontal lines in the boxes present the medians; the X signs show the means; the extending
323 vertical lines illustrate the ranges; and the dots that exceed the line represent outliers.

324

325 **DISCUSSION:**

326 Despite the unprecedented humanitarian crisis in Syria, Syrian students sought to develop their
327 research skills by attending numerous in-house and online workshops conducted through Syrian
328 efforts or provided by international organizations. This study was novel in providing a broad
329 overview of the characteristics and effectiveness of all these interventions used during the first
330 ten years of the Syrian armed conflict. We first proved that attending more of these workshops
331 was associated with higher research knowledge, attitudes, and productivity. Then, we showed
332 that self-reported research knowledge had particularly the strongest correlation with the number
333 of attended workshops and was also the strongest predictor of the number of conducted and
334 published research projects. Additionally, we could, using participants' evaluations, show that
335 these extracurricular interventions were more effective than curricular training and as valuable as
336 practical peer support during ongoing research projects. Finally, we presented a scheme
337 summarizing all the modifiable personal factors that play a role in improving or hindering research
338 productivity in our limited resources settings (Fig 6).

339

340 Fig 6: A scheme depicting all the investigated factors that affect research productivity among early
341 career health professionals as well as the interrelations among them.

342 Fig 6 Legend: The blue arrows represent significant positive correlations; the orange arrows
343 illustrate significant independent predictors with the dependent variable ahead of the arrow; and
344 the green arrows depict significant association with higher effectiveness or recruitment of the
345 extracurricular trainings.

346

347 Even in countries where research training is deeply rooted as a part of the curriculum, research
348 workshops seemed to be the most effective way of training (22). These workshops are also widely
349 recognized as an effective tool for promoting medical research in low- and middle-income
350 countries (LMICs) (23–25). In Syrian, they were suggested as an attainable alternative to address
351 the shortcomings of the research curriculum (10,16). Previous reports assessing individual
352 interventions that targeted research skills including EBM and academic writing in Syria highlighted
353 the knowledge-enhancing effects of their workshops (11,13,14,26), or at least improvement
354 limited to attendees' confidence (27), or perceived skills (15). Additionally, a recent cross-
355 sectional study on Syrian residents suggested that attending more trainings on medical research
356 correlates with better practices of EBM (28). We similarly proved that attending more research
357 workshops has a significant positive impact on research-related knowledge. Although this finding
358 comes in line with previous reports, it uniquely generalizes their findings employing a novel
359 comprehensive assessment that pooled all eligible interventions in the study period and recruited
360 a large sample size from several universities and academic levels.

361 Our findings also confirmed that participants who attended more workshops reported higher
362 attitudes towards research, which was described as a major outcome of one workshop targeting
363 EBM.(26) Notably, attitudes towards research were less strongly correlated with workshops
364 attendance compared to knowledge. We can attribute that to the fact that medical personnel in
365 Syria, even those who have never conducted any research project, generally reported high

366 attitudes towards research (10,16), and this does not apply to the poor research-related
367 knowledge repetitively reported (21,28,29). The weak impact of workshops on attitudes can also
368 be due to the limited effectiveness of workshops in addressing certain research barriers, such as
369 language, internet connection, and time availability (10,11,16,29), thus, hindering attitudes
370 strengthening towards medical research.

371 Despite that, when it comes to studying the improvement in research productivity, trainings on
372 research skills can achieve it in several pathways (Fig 6). Our previous article established that
373 self-reported knowledge explains much of the variability in the number of conducted and
374 published scientific papers (21). The current study also proves that attending research-related
375 workshops as an independent factor has a positive additional value on research conduction. This
376 can be attributed to the development of leadership and time management skills through
377 extracurricular activities (30) and the possibility to engage more effectively in the research
378 community during such trainings (31). The extracurricular workshops in Syria were also
379 suggested to help in establishing research networks that foster research knowledge and
380 participation, in addition to enhancing students' understanding of research materials (10,20). The
381 higher research productivity we found among participants who attended longer workshops
382 supports this logic, as the time by itself may offer a higher probability to the establishment of the
383 aforementioned research networks. Although, the literature suggests that shorter courses can be
384 of higher feasibility and effectiveness (12,32), they might not offer further mentorship after the
385 training (33), possibly suggesting a lower impact on research productivity, which meets our
386 findings.

387 Although MOOCs and traditional learning showed similar effectiveness in medical education by
388 means of a meta-analysis (34), MOOCs remain a valuable, and sometimes the only, asset in
389 LMICs to acquire the needed knowledge and skills to conduct research projects (35). In line with
390 that, our study found that participants who attended MOOCs reported higher knowledge and

391 research productivity than those who attended other workshops. This can be explained by the
392 findings of Li et al, which highlighted that MOOCs attendees tend to have higher motivation to
393 learn (36). The open-structure of MOOCs also allows students to design their individual learning
394 objectives depending on their needs (37). Therefore, we can speculate that participants who had
395 running projects preferably attended MOOCs to address the specific knowledge gaps they faced
396 during the progress of their projects, which could be the reason behind the higher knowledge and
397 research conduction we found among MOOCs attendees. A similar pattern was evident in an
398 academic writing workshop, where participants who practiced research skills through writing
399 assignments gained higher objective knowledge than those who did not achieve these
400 assignments (13).

401 Although the investigated workshops were in general effective in improving research knowledge,
402 attitudes, and productivity, it is difficult to believe that Syrian healthcare personnel leveraged from
403 the full capacities of these interventions. It was quite evident that these interventions lacked a
404 consistent pattern across the different cities and varied in terms of content, delivery, and targeted
405 group(s). This lack of organization can be attributed to the fact that they were in most cases driven
406 by the needs in their proximity, which suggests a significant room for improvement if they become
407 tailored based on up-to-date representative assessments of the needs and barriers towards
408 research (10,13,16,21). On the other hand, we assume that the lack of institutional collaborations
409 constrained the amplitude of benefit, especially from in-house workshops, to specific groups and
410 locations. Therefore, it is important to emphasize the role of the concerned faculties and ministries
411 in organizing research training efforts. This is particularly relevant in developing countries, where
412 personnel with decision-making capacities are less involved in the scientific progress (38).

413 Nevertheless, this study emphasized the role of peers in pushing the wheel of research training
414 in Syria (9). The vast majority of in-house trainings, as well as some online workshops, in our
415 analysis relied heavily or completely on under- or postgraduate peer trainers with wider research

416 experiences and higher research-related knowledge and attitudes. This role of peers was
417 particularly underlined in countries grappling with significant training gaps and depletion of
418 professionals, as reported in the Syrian case (10,11,13,16). The reliance on peers in such settings
419 is both justified and indispensable, as peer-led training presents a practical and affordable solution
420 that alleviates the burden on professors and faculty members (39,40). Superiority of peer training
421 might also be argued, as one study also reported negative experiences (e.g., uncomfortable
422 interaction) in extracurricular activities delivered by faculty members (30). Notably, the support
423 from peers extended beyond extracurricular trainings to personalized peer-to-peer assistance
424 during ongoing research projects (9,16). Our study further underscored that these two forms of
425 peer-support are of comparable value in the gained knowledge, attitudes, and practice.
426 Interestingly, both of these methods were significantly more valuable to beneficiaries than the
427 previously deemed substandard curricular research training (10,11,16), suggesting them as an
428 established solution for the dearth of expertise in Syria (13).

429 **Limitations:**

430 In spite of the strengths that reside in our sample and methodology, our findings still provide proof
431 of association rather than causality. For instance, it might be argued that participants with higher
432 knowledge, attitudes, and more research projects are those who attend workshops training
433 research skills. However, this remains unlikely for two reasons. First, this explanation does not
434 justify how high our participants evaluated the best workshops they attended (S. Fig 1). Second,
435 a significant group of participants had multiple research projects despite declaring that they never
436 attended any workshop training research skills (Fig 5). On the other hand, one systematic review
437 suggests that increased knowledge may be driven by medical students' motivation to achieve
438 higher grades on curriculum-based assessments (41). This explanation does not apply to our
439 sample, as several reports described how Syrian researchers lack the institutional and curricular
440 motivation to perform research (10,11,16). Additionally, the academic scores of our participants

441 did not correlate with any measure of attitudes towards research (21). Moreover, the tool we used
442 remains subjective and lacks the objectivity in assessing research-related knowledge in particular.
443 It might have also been affected by recall bias as some of the trainings were ten years old by the
444 time of data collection. Finally, as many participants attended a mixture of workshops of different
445 characteristics, it was quite difficult to purely assess the impact of each of their characteristics
446 individually. However, we believe that the clustering methods we used in addition to the self-
447 evaluation of the best workshops are the best feasible approaches to overcome this obstacle.

448 **Conclusion:**

449 The extracurricular interventions targeting medical research paucity in Syria have proven
450 successful in helping Syrian early-career medical researchers to find their voice (27). Regardless
451 of the dreadful circumstances of war, these workshops increased research attitudes, knowledge,
452 skills, and productivity, and facilitated engagement in the research community. Local peers and
453 international professionals played crucial roles in this progress; however, these efforts still lack
454 the institutionally-organized framework that can be achieved by joining forces with medical
455 faculties.

456

457 **DECLARATIONS:**

458 **Acknowledgements:**

459 The authors are grateful to Luma Haj Kassem and Ahmad Naem for their support in data
460 collection.

461 **declaration of interest:**

462 None of the authors have any conflict of interest that is relevant for this project.

463 **Contributions:**

464 IH conceptualized the project. IH, MA, KK, ARR collected the data. IH, RS, and ARR analyzed
465 and interpreted the data. IH, MA, KK, and MGN prepared the manuscript. IH supervised the
466 project. All authors revised and approved the final version of the manuscript.

467 **Ethical approval and consent for publication:**

468 The ethical approval for this study (30/2020) was obtained from the institutional review board of
469 Damascus University on 19.01.2021. All participants provided their written informed consent for
470 the publication of their anonymous data before their participation.

471 **Data availability statement:**

472 The data supporting this manuscript is available and can be provided upon reasonable request to
473 the corresponding author.

474 **Funding:**

475 None of the authors received any funding from any agency that is related to the work on this
476 project.

596

597 **PRACTICE POINTS:**

598 Syrian extracurricular training initiatives positively impact knowledge, attitudes, and research
599 productivity among early career healthcare professionals.

600 Expanding extracurricular initiatives could offer a maintainable method to significantly enhance
601 research capacity in resource-constrained settings.

602 Massive open online courses and longer-duration trainings are more effective in achieving these
603 outcomes.

604 Policymakers and educators may incorporate these initiatives to optimize research outcomes
605 despite limited resources.
