Abstract

Background: Previous viral outbreaks have highlighted implications for the management of complex health conditions. This study delves into the repercussions of the COVID-19 pandemic on stroke care, by examining evidence of shifts in healthcare utilization, the enduring effects on post-stroke recovery, and the overall quality of life experienced by stroke survivors.

Methods: A scoping review was conducted following the Joanna Briggs Institute Methodology for Scoping Reviews. The search strategy encompassed electronic databases (APA PsycInfo, Embase, Medline, and CINAHL). English language articles published between December 2019 and January 2022 were included, focusing on individuals who experienced a stroke during the COVID-19 pandemic. Data extraction involved identifying study characteristics and significant findings, facilitating a qualitative and narrative synthesis of the gathered evidence.

Results: Seven domain summaries were identified. They all described the aspects of systemic transformations in stroke care during the COVID-19 pandemic: (1) patient behavior and awareness; (2) telemedicine and remote care; (3) delays in treatment; (4) impact on healthcare resources; (5) quality of care; (6) changes in stroke severity; and (7) reduction in stroke admissions.

Conclusions: This study underscored the critical need to encourage swift patient response to acute stroke symptoms, by finding new avenues for treatment, mitigating hospital-related infection fears, and advocating for the establishment of centralized stroke centers. These measures are integral to optimizing stroke care delivery and ensuring timely interventions, particularly in the challenging context of a pandemic.

TIA Transient Ischemic Attack

INTRODUCTION

Past large-scale outbreaks, exemplified by the 2015 Middle East Respiratory Syndrome (MERS), have been associated with changes in the utilization of emergency care services for conditions such as ischemic stroke and myocardial infarctions¹. Similarly, the COVID-19 outbreak, as a result of SARS-CoV-2, demonstrated an impact on the management of cardiovascular disease². The World Health Organization (WHO) emphasizes the necessity of drug treatment for hypertension, diabetes, and hyperlipidemia in effectively managing cardiovascular diseases³. Successful cardiovascular management requires patients to be involved in their care, having social and interprofessional support, and consistent follow-ups with healthcare providers⁴. Although these comprehensive approaches to stroke are crucial, when COVID-19 spread across regions worldwide, there were escalating concerns regarding the capacity of global healthcare systems to meet rising demands for acute emergencies and provide effective rehabilitation services for individuals who experienced strokes⁵. In this review, we assess the global impact of the COVID-19 disaster on stroke care, focusing on evidence for changes in healthcare access and utilization, long-term impacts on post-stroke recovery, and the quality of life of stroke survivors.

The WHO declared the COVID-19 pandemic on March 11th, 2020, catapulting many countries into a state of emergency⁶. Many institutions reported that this affected hospital resource allocation and well-established pathways for care⁷. This includes the protocols and process measures for the care/management of stroke⁷, the second leading cause of death and the foremost cause of disability worldwide^{8,9}.

Each year, 15 million individuals around the globe experience a stroke¹⁰. To address the challenges posed by COVID-19 on healthcare systems, novel strategies were introduced to enhance in-hospital workflow, optimize the availability of healthcare workers, and minimize risks

for patients, families, and care partners^{8,11}. These changes largely affected people experiencing stroke and other non-COVID-19 conditions, which required extensive resources related to imaging, diagnostics, treatment options, and length of stay¹². The impact of the ongoing crisis on stroke care continues to be influenced by in-hospital decisions, regional public health protocols, prehospital triage, and equitable access to acute treatments¹³. It is also the result of different statewide strategies to prevent and contain the spread of COVID-19¹⁴. These strategies (e.g. quarantine, isolation, screening and triage protocols), may not only influence traditional stroke pathways but also health-seeking behaviors¹⁵.

The negative impacts of preventative public health initiatives that target the spread of infections within hospitals have been recognized, and they are anticipated to give rise to various epidemiological consequences (e.g., increased mental health disorders, antibiotic resistance)¹⁶. As the pandemic persists, there will likely be a continued shift in the epidemiology of stroke and other cardiovascular events¹⁷. In Italy, the restrictive lockdown required adaptations of the integrated care pathways (ICP) serving stroke and other time-dependent conditions¹⁸. In the United Kingdom, non-urgent elective care was paused as the English National Health Service (NHS) reprioritized the delivery of care for COVID-19 patients¹⁹. In the United States, emergency treatment protocols, such as for thrombolysis and endovascular revascularization, were at risk of significant time delays²⁰. The urgency imposed by COVID-19 pushed these rapid public health reforms. With minimal forewarning and planning, healthcare institutions were forced to swiftly formulate, communicate, and implement an organizational response to the pandemic. This involved recalibrating healthcare delivery to strike a balance between providing timely and effective care while mitigating the risk of COVID-19 infection. For example, the American Heart Association and American Stroke Association quickly issued temporary emergency guidelines for stroke

hyperacute management²¹, and the Canadian Stroke Best Practice recommendations were rapidly modified to provide a virtual tele-stroke healthcare management-toolkit²².

During disasters, stroke survivors are likely to experience serious disruptions that can impact social, cognitive, and motor outcomes²³. The impacts of the pandemic on stroke survivors produced "collateral damage" ²⁴, yet the global evidence for the direct and indirect impacts of the COVID-19 pandemic on stroke care has yet to be synthesized. Hence, to support knowledge mobilization, the purpose of this scoping review is to form an evidence-based framework to describe the resiliency and capacity of stroke care systems during the pandemic and to formulate recommendations for reducing the risks for stroke patients during an emergency/disaster. This knowledge will inform future emergency preparedness protocols supporting effective response and highlight the needs of stroke survivors in a disaster context.

METHODS

Scoping review methodology allows researchers to navigate the landscape of evidence by exploring emerging findings in situations where clarity is lacking, allowing for the formulation of more comprehensive and specific questions²⁵. The value of conducting this study as a scoping review is that it will inform evidence-based practices in the broader field of cardiovascular healthcare service delivery by identifying gaps in the research knowledge base²⁵. The Joanna Briggs Institute (JBI) Methodology for Scoping Reviews²⁶, provides a contemporary methodological framework to facilitate knowledge translation in health research. This framework instructed our reporting outline, inclusion criteria, search strategy, extraction, presentation and summarization of the results, and any potential implications for research and practice.

Search strategy

The following four electronic databases were systematically searched as shown in the PRISMA chart in Appendix A: APA PsycInfo, Embase, Medline, and CINAHL. Additionally, grey literature was hand-searched using open-access repositories and the reference lists from selected articles. Two levels of search terms were used: (1) terminology for stroke and (2) the COVID-19 pandemic. The protocol for the review design and search strategy was developed by study researchers (MY, SO) and health science librarians from the University of Ottawa Library (KF & NL) prior to database searches. The search strategy is presented in Appendix B. Guidelines from the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews (PRISMA-ScR) were followed, and the PRISMA-ScR checklist, which guides the reporting of scoping reviews was completed²⁷. This reporting guideline is consistent with the JBI guidance for scoping reviews and highlights the importance of methodological rigor in conducting scoping reviews²⁵.

Study screening and selection

All stages of the screening process (i.e., title and abstract screening, full text screening and selection) were completed using Covidence. Two researchers (MY, SO) participated independently at each stage. In the case of any discordance between authors' selection, there was a discussion between co-authors (MY, SO, IM, AM & KS) to reach a consensus regarding the inclusion or exclusion of the article.

English language articles published between December 2019 (the inception of the COVID-19 pandemic) and January 2022 were included. Population characteristics include people who had a stroke (clinically defined as hemorrhagic stroke (intracerebral and subarachnoid), ischemic stroke, TIA, or any condition that can be classified as a cerebrovascular accident) during the

COVID-19 pandemic, as defined by the period between when SARS-CoV-2 was initially identified as a threat - to January 2022. The outcomes of interest of selected articles were the impact of the COVID-19 pandemic on individuals who had a stroke, including stroke care during the pandemic, changes in healthcare delivery, functional outcomes, and quality of life after stroke. Articles presenting original research findings or analyses thereof were included, including primary and secondary data, or synthesis of available literature reflecting the functional outcomes of patients who had a stroke.

Studies were excluded if the outcomes of interest were the impact of SARS-CoV-2 on stroke symptoms, stroke as a complication or prognostic factor of SARS-CoV-2, or risk of stroke in people who contracted COVID-19. Opinion pieces, commentary papers and recommendation papers were excluded if they did not report on empirical results from an original study. Articles from the position of, or solely focusing on the experiences of, Health Care Professionals (HCPs) were excluded.

Data collection and analysis

Authors (MY, IM, AM & KS) jointly developed a data-charting table to determine the variables to extract. Extraction was initially conducted by one author (MY) and confirmed for accuracy by other authors (IM, AM & KS). All authors iteratively updated the extraction tables. We extracted data on study characteristics (Appendix C), including year, country, study design, and significant findings from the manuscripts. A comprehensive qualitative and narrative synthesis of the gathered data was performed in preparation for a content analysis²⁸. The authors refined the analysis and presentation through thoughtful deliberations and consensus-building, particularly when adjustments were required or in the presence of conflicting opinions. To establish coding reliability, title and abstracts were dually coded, followed by the full inclusion of articles. Title

and abstract screening for interrater reliability was initially performed by MY and SO, resulting in a strong agreement with a kappa value of 0.85. Following this, a secondary screening of the 84 included articles was carried out by AM and KS, yielding a kappa value of 0.9, indicating strong agreement.

RESULTS

Study characteristics

The search and screening processes are presented in Appendix A. We identified a total of 861 studies after the removal of duplicate studies. A total of 650 records were excluded following title and abstract screening. Of the 211 full articles assessed for eligibility, 84 met inclusion criteria and were retained.

The included articles underwent a reevaluation by three members of the research team (KS, IM & AM) to further confirm their eligibility for inclusion. The included articles were composed of 46 retrospective studies (cohort (n=7); observational (n=11); cross-sectional (n=3); archive (n=1); review (n=1); unspecified (n=23)); 10 prospective studies (cohort (n=2); observational (n=3); cross-sectional (n=3); unspecified (n=2)); 26 observational studies (reports (n=9); cohort (n=7); cross-sectional (n=1); unspecified (n=9)); one matched pairs study; and one survey and one exploratory design. The included articles demonstrated wide geographical spread spanning Bangladesh²⁹; Canada^{30–32}; Chile³³; China^{15,34–37,37–44}; Egypt⁴⁵; Finland⁴⁶; France⁴⁷; Germany^{48–50}; India⁵¹; Iran^{52,53}; Israel^{54–56}; Italy^{8,57–67}; Japan^{9,68}; Lithuania⁶⁹; Malaysia⁷⁰; Netherlands⁷¹; Norway^{72,73}; Saudi Arabia^{74,75}; Spain^{76–79}; Switzerland⁸⁰; Taiwan⁸¹; United Kingdom^{82–84}; and United States of America^{7,20,24,39,85–104}. The studies encompassed participants from a wide range of diverse backgrounds, including individuals from various racial and ethnic communities, linguistic

minorities, and persons with differing levels of disability. A wide range of ages was also captured

in the articles ranging from early to late adulthood.

Review findings

A total of seven domain summaries were identified through content analysis²⁸. This

analytical approach embraces the consideration of multiple perspectives to gain a comprehensive

understanding of a specific area of focus in a given timeframe (i.e., stroke care during the COVID-

19 pandemic), through systematic content analysis 105. After becoming familiar with the data,

domains were developed, and summaries for each domain were compiled. The domain summaries

reflect the diverse ways in which the COVID-19 pandemic affected stroke care globally. They

highlight the challenges faced by healthcare systems in maintaining quality stroke care amid the

disruptions caused by the pandemic. These domain summaries include: (1) patient behavior and

awareness; (2) telemedicine and remote care; (3) delays in treatment; (4) impact on healthcare

resources; (5) quality of care; (6) changes in stroke severity; and (7) reduction in stroke admissions.

The domain summaries were then grouped into three domains: patient conduct, healthcare

delivery, and stroke characteristics, as depicted in Figure 1.

Domain 1: Patient conduct

Domain Summary 1: Patient behavior and awareness

Patient behavior, such as the reluctance to seek medical attention, emerged as a significant

factor affecting stroke outcomes during the pandemic. The fear of contracting COVID-19 and

changes in healthcare-seeking behavior were recurrent themes 42,77,96. Individuals experiencing

mild stroke symptoms and those with lower functional abilities were less inclined to seek medical

attention^{7,42,59,77}. Patients tended to delay seeking medical help, often surpassing the eligible

treatment timeframes^{33,39}. Additionally, external factors such as national traffic control measures

(for example, in China) played a role in hindering prompt access to healthcare services¹⁵.

Moreover, the implementation of additional COVID-19 prevention protocols, such as mandatory

travel history checks, contributed to prolonged stroke management periods¹⁵.

Domain Summary 2: Telemedicine and remote care

Amid the pandemic, there was a surge in patient reliance on telemedicine for stroke

consultations and follow-ups, particularly for non-acute treatment, as noted in numerous

studies 31,77,79,87,90,92. This shift in healthcare delivery aimed to address pandemic-related challenges

and ensure ongoing patient care. However, despite these efforts, older adults experienced a

reduction in weekly telestroke consultations and decreased utilization of telestroke services²⁴.

Conversely, there was a significant decline in in-person outpatient visits and inpatient care for

stroke patients, particularly affecting high-risk populations such as immunocompromised

individuals and those with underlying health conditions ^{31,77,79,87,90,92,99}. While telemedicine became

increasingly common for both new and existing patients in younger cohorts, outpatient clinics that

remained operational implemented stringent safety measures such as the use of personal protective

equipment (PPE) and isolation protocols^{36,37,42,46,87}.

Domain 2: Healthcare delivery

Domain Summary 3: Delays in treatment

The focus on COVID-19 patients and facilities led to a restructuring of pre-hospital

transportation, decreased interactions with stroke specialists, centralization of stroke centers and

rehabilitation routes, a reduction in the availability of additional diagnostic tests, timely therapies,

and emergency pathways for stroke patients 45,51,82. These changes resulted in delays, which in turn

affected the utilization of immediate treatments, and had implications for prognosis⁷⁶. The advent

of the COVID-19 pandemic prompted a shift in healthcare priorities, diverting attention and resources away from routine stroke care, including the essential procedures of thrombolysis and thrombectomy^{20,45,72,104}. As a result, the pandemic caused a strain on healthcare systems, resulting in a noticeable decline in the performance of these two critical interventions by skilled practitioners such as cardiologists, radiologists, vascular surgeons and emergency medicine physicians^{20,45,72,104}. Fewer referrals for specialized stroke care were made during the pandemic^{48,55,69,75,83,98}. Factors contributing to these delays included changes in hospital protocols, reorganization of healthcare resources, and changes in patient health-seeking behaviors as a result of fear 42,77,96. The crowding of hospitals during the COVID-19 pandemic not only led to delayed acute treatment for stroke patients, 75 but also resulted in increased symptoms-to-door time (i.e., the time between the onset of symptoms and arrival at the hospital) and door-to-treatment time (i.e., the time between arrival at the hospital and the initiation of treatment) for reperfusion. ^{30,34,60,76,79}. However, prehospital triage proved helpful in the provision of timely care in resource-limited areas⁶⁹. Notably, some hospital Emergency Departments implemented two distinct intra-hospital pathways to ensure the safe management of stroke patients⁶⁵.

Domain Summary 4: Impact on healthcare resources

The reorganization of healthcare resources, reallocation of stroke professionals, and the prioritization of COVID-19 patients⁵⁹ led to changes in stroke care pathways, delays in acute treatment⁷⁵, and consequences for stroke outcomes⁷⁶. Ambulance services experienced an excessive burden due to the pandemic⁵⁸. There was also an increase in the demand for computed tomography (CT) scans¹⁰⁰; discontinuation of rehabilitation programs due to the reorganization of resources; shortfalls in health insurance coverage for stroke patients; and limited access to

specialized care units and diminished workforce in hospitals ^{59,68,74,102}. Ultimately, these pandemic-

related healthcare interruptions led to a fragmented stroke chain of survival and care pathways.

Domain Summary 5: Quality of care

During the COVID-19 pandemic, reductions in quality-of-care metrics, including door-to-

CT (time from arrival to hospital and initiation of a CT scan), dysphagia screenings, early

antithrombotic use, and rehabilitation evaluations, were observed in various

studies^{70,77,81,83,90,99,100,102}. Despite discussions about the preservation and, in some cases,

improvement in stroke care quality during the pandemic^{20,81,82}, challenges and disruptions in

outpatient care, rehabilitation, and follow-up care were noted in several articles^{6,7,30,62,65,66}.

Furthermore, studies indicated that patients treated during the pandemic had worse discharge

outcomes and increased mortality rates^{20,33,85}. Regrettably, higher rates of in-hospital death and

hospice discharges were observed during the pandemic period, attributed to longer treatment

delays 16,26,79,87. Additionally, higher post-stroke disability (e.g., loss of peripheral vision, muscle

spasticity, hemiplegia¹⁰⁶), measured using the modified Rankin Scale, was correlated with the

discontinuation of rehabilitation services due to the pandemic^{74,102}.

Domain 3: Stroke characteristics

Domain Summary 6: Changes in stroke severity

During the pandemic, noticeable shifts in stroke severity were observed, with many studies

highlighting an escalation in the severity of strokes compared to pre-pandemic

measures^{33,40,48,63,91,98,103}. Particularly noteworthy is the finding that stroke severity upon hospital

admission was significantly higher in the pandemic period compared to pre-pandemic cohorts^{48,91}.

This phenomenon may be attributable to delayed patient presentations; a lack of close observers

to notice stroke symptoms due to lockdowns and stay-at-home directives; and a hesitancy among

individuals to promptly seek medical attention.

Domain Summary 7: Reduction in stroke admissions

Many articles discussed the impact of the COVID-19 pandemic on hospital admissions for

stroke patients^{9,15,29,36,40,44,45,47–54,58,60,61,65,66,69,71,72,82,83,86,88,91,103,104}. A few articles mentioned a

 $decrease in the number of stroke admissions during the pandemic {}^{29,39,40,52,53,69,72,76,77,79,83,84,90,97,107}\\$

despite reperfusion therapy, thrombolysis and thrombectomy rates remaining unchanged during

this period^{50,54,63,65,71,91}. There were also fewer presentations of emergent large vessel occlusion

(ELVO) in the emergency departments⁴⁵, less stroke unit admissions^{8,64,79}, and fewer code

strokes^{77,79}. A reduction in transfers between facilities was also observed, likely attributed to

precautionary measures implemented early in the pandemic to minimize the risk of COVID-19

transmission through interfacility transfers^{57,98,108}. These reductions in stroke admissions were

attributed to factors such as patient reluctance to seek medical care, fear of infection, and changes

in healthcare protocols^{61,77,82,96}.

[PLACEHOLDER – Figure 1. Systemic and interrelated transformations in stroke care

during the COVID-19 pandemic presented as a framework]

DISCUSSION

In this scoping review we aimed to explore the repercussions of the COVID-19 pandemic

on stroke care, examining evidence concerning shifts in healthcare utilization, the enduring effects

on post-stroke recovery, and the overall quality of life experienced by stroke survivors. A thorough

literature search uncovered 84 articles that satisfied the inclusion criteria for this review. Included

articles reflected the condition of stroke care at healthcare facilities or the stroke experiences of

individuals from several continents. Findings from the articles were analyzed using content analysis¹⁰⁵. This resulted in three domains: patient conduct, healthcare delivery and stroke characteristics; and seven domain summaries: (1) patient behavior and awareness; (2) telemedicine and remote care; (3) delays in treatment; (4) impact on healthcare resources; (5) quality of care; (6) changes in stroke severity; and (7) reduction in stroke admissions, as presented in Figure 1.

The results of the current review align with existing literature wherein pandemic-related health measures and states of emergency affect the likelihood of seeking medical care during acute cardiovascular incidents¹⁰⁹. Current research suggests that states of emergency influence patient behavior by decreasing admission rates for cardiovascular events and causing broader shifts in health-seeking behaviors¹⁰⁹. Similarly, results from this review indicate that patients feared contracting SARS-CoV-2, thus when making health-related decisions, the risk of being admitted to a hospital for an acute cardiovascular event was weighed against the risk of COVID-19 mortality for older and/or institutionalized patients¹¹⁰.

In sum, the impact of COVID-19 on stroke care was multifaceted, with social isolation and stay-at-home orders contributing to fewer witnesses of stroke symptoms, delayed recognition of mild stroke signs, and increased avoidance of advanced care^{7,42,59,77}. Raising awareness about stroke symptoms and the critical need for immediate medical attention, even amidst a pandemic, is paramount¹¹¹. This effort can encompass diverse strategies, including public service announcements, targeted social media Face, Arm, Speech, Time (FAST) campaigns during lockdowns, and proactive community outreach initiatives¹¹². Additionally, fostering support networks through structured systems of assistance within communities to aid individuals experiencing stroke symptoms, particularly those who are socially isolated or face barriers in seeking assistance, is essential for mitigating adverse stroke outcomes during times of crisis¹¹³.

Amidst crises, stroke care systems face numerous challenges, including delays in hospital presentation, ineligibility for time-sensitive treatment, and a reduction in thrombolysis and thrombectomies^{20,45,60,86}. To address these challenges, adaptability in stroke care systems is essential. Recent research has indicated that the successful implementation of performance improvement programs and robust stroke care systems can help maintain high-quality care during health emergencies¹¹⁴. Additionally, mitigating delays and preventing reluctance to seek medical care requires addressing various factors such as overcoming fear of COVID-19 infection¹¹⁵; managing transportation restrictions (i.e., many individuals indicated being ensure whether travel to hospital was permitted and feared exposing patients to COVID-19¹¹⁶), and alleviating burdens on the healthcare system. Notably, innovations have been proposed to alleviate these burdens and safeguard stroke survivors during crises, including: (1) implementing teleneurology networks to enhance thrombolysis access for acute ischemic stroke; (2) enhancing the efficiency of emergency care for acute ischemic stroke (e.g., by preregistering patients during transport via ambulance and having the neurologist obtain clinical history electronically prior to arrival at the hospital); and (3) offering alternatives to inpatient care for transient ischemic attacks through an accelerated diagnostic protocol in the observation unit¹¹⁷.

This emphasizes the importance of rapid adaptation and multidisciplinary changes in stroke care protocols, including effective triage screening, proper PPE utilization, and increased equipment cleaning to minimize treatment delays¹¹⁸. Recognizing the impact of social isolation and the stress of the pandemic on the mental health of patients and staff also underscores the need for comprehensive psychological support measures in stroke care strategies¹¹⁹. To address COVID-19-related fears, stroke care must include the integration of psychological support, particularly emphasizing the consideration of physiological risk factors linked to COVID-19

comorbidities¹¹⁵. For future preparedness, a holistic approach that encompasses technological advancements, public education, and mental health support will be essential to ensure optimal patient outcomes and maintain the integrity of stroke care systems during crises. Findings from this review also point to a need to compare the quality of stroke care delivered through telemedicine with that provided in traditional, in-person settings.

Strengths and limitations

While the scoping review offers valuable insights into the challenges faced by stroke care systems and survivors during the COVID-19 pandemic, it is important to acknowledge certain limitations. One notable limitation is the restriction of the search to English language articles, which may have resulted in the exclusion of relevant studies published in other languages, potentially limiting the comprehensiveness of the review. However, by analyzing studies from multiple continents and considering diverse populations, the review provides a global perspective on the challenges faced by stroke care systems during the pandemic. Additionally, the review includes articles published only up to January 2022, which may not capture the most recent developments in stroke care during the ongoing pandemic. Furthermore, while the review offers a qualitative synthesis of the literature, the absence of quantitative analysis limits the ability to quantify the magnitude of the impact of COVID-19 on stroke care outcomes. Despite these limitations, the review provides a thorough examination of the impact of the COVID-19 pandemic on stroke care, encompassing various aspects such as changes in healthcare utilization, long-term effects on post-stroke recovery, and quality of life considerations for stroke survivors. The use of scoping review methodology, guided by the JBI framework, ensures a systematic and transparent approach to navigating the available evidence.

16

Conclusions

As evidenced by our scoping review, the COVID-19 pandemic has profoundly altered

stroke care around the globe. Heightened patient fear and subsequent delays in seeking medical

attention, coupled with rapid shifts towards telemedicine, highlight the urgent need for adaptable

stroke care systems. Recommendations include prioritizing telemedicine and improving its access

to older adults and high-risk populations; and implementing robust performance improvement

programs to mitigate treatment delays. Future research should explore strategies for enhancing

patient education and communication to address fear-related delays in seeking medical attention.

Longitudinal studies tracking the long-term effects of pandemic-induced changes in stroke care

delivery are also needed for understanding their sustained impact and informing future emergency

preparedness protocols.

Appendix C. Included studies exploring stroke care during the COVID-19 pandemic.

Author/Year	Purpose	Design/Methods	Main Findings
Bangladesh			
Hasan et al. [29]	Examine the impact of COVID-19 on the admission of acute stroke patients.	Retrospective	There was a reduction in stroke admission per month and number of patients getting reperfusion treatment.
Canada			
Dowlatshahi et al. [31]	Perform a rapid review of stroke care delivery at our comprehensive stroke center (CSC) and through the provincial telestroke system, both before and after the pandemic "shutdown."	Retrospective	Thrombolysis and endovascular thrombectomy rates remained constant. Fewer patients received stroke services across the spectrum from prevention, acute care to telestroke care in Ontario, Canada, during the COVID-19 pandemic.
Katsanos et al. [30]	Investigate the impact of regional imposed social and healthcare restrictions on management of AIS patients.	Retrospective	After the state of emergency was imposed, there was an increased door-to-CT time, and DNT for those receiving intravenous tPA or EVT.
Neves Briard et al. [32]	Study the impact of the COVID-19 pandemic on stroke treatment metrics.	Observational cohort	During the pandemic, longer delays between stroke onset, initial evaluation, and reperfusion therapy was observed. In-hospital infection control measures may have delayed acute stroke management.
Chile		<u> </u>	
Silva-Pozo et al. [33]	Analyze the impact of the COVID-19 pandemic outbreak on hospital ischemic stroke admissions, use of reperfusion therapies, and mortality.	Observational	There was an increase in severity of ischemic stroke on admission and in-hospital mortality during the pandemic. There were not significant changes to admission and intervention rate.
China			
Chen et al. [24]	Determine whether COVID-19 affected the treatment and prognosis of hemorrhagic stroke in a reginal medical center.	Retrospective	During the pandemic, there were milder and less stroke presentations, longer door-to-department times, and higher rate of pneumonia complications. Clinical outcomes of patients during the pandemic were worse than those during pre-pandemic.
Gu et al. [15]	Evaluate the impacts of the COVID-19 on treatment delays of AIS.	Retrospective	Patients experienced both pre- and post-hospital delays after the start of the COVID-19 pandemic. This impacted the smaller proportion of AIS patients receiving intravenous thrombolysis. Delayed treatment was

Jing Zhao et al. [36]	Compare the impact of the COVID-19 pandemic on outpatient stroke clinics and inpatient services.	Survey	associated with lower education levels, rural residency, mild symptoms, small artery occlusion, and transportation of than ambulance. The COVID-19 pandemic caused a significant drop of in-person outpatient visits and inpatient services for stroke. Outpatient clinics that were open exercised increased precautions following recent guidelines regarding the use of PPE and isolation techniques. Telemedicine was used for new and
Li et al. [38]	Examine the management of endovascular treatment for AIS during the pandemic.	Retrospective observational	follow up patients. Patients admitted during the pandemic had longer time between symptom onset and recanalization, longer neuro-intensive care unit length of stay, and higher hospitalization costs.
Wang et al. [39]	Compare emergency visits and efficiency of stroke treatment pre-, early, and peak, and late pandemic	Retrospective	During early and peak pandemic, there was a lower rate of hospital admissions but higher rate of MT for stroke. Medical practice strictly followed hospitals contingency plans and the new national expert consensus on stroke treatment.
Wu et al. [40]	Investigate the impact of the COVID-19 outbreak on stroke emergency care during the pandemic.	Retrospective	There was a significant reduction and delays in stroke emergency admissions during the lockdown period. Stroke severity also increased during this time.
Xin et al. [41]	Understand how COVID-19 affected stroke care systems.	Retrospective	During the pandemic, there were no differences in pre-hospital or in-hospital workflow metrics while the degree of neurological deficit, treatment effects and long-term prognosis were worse. Rates of admission were maintained.
Yao et al. [42]	Conduct interviews with community residents to investigate actions took by community residents after onset of stroke symptoms. Explore factors associated with seeking timely	Prospective cross- sectional	Residents who suspected TIA often avoided seeking medical attention when their symptoms disappeared quickly. The pandemic was found to influence their behavior as there was fear of infection from community health centres as well as fear that the

	medical attention during the pandemic.		pandemic would necessitate complicated procedures at the centres. However, those who sought medical attention were more often males, those with a previous history of stroke, and residents who had a dual attack within a week with aphasia or dysarthria.
Zhang et al. [43]	Report on stroke care in a regional hospital.	Retrospective	A regional telestroke network was constructed as a Hub and Spoke model to extend stroke care in a resource-limited area. Fever clinical was incorporated into the stroke pathway during the pandemic. Prehospital triage provided timely transfer of stroke patients while minimizing risk of infectious exposure. There was a reduction in stroke admissions and longer treatment times.
Zhang et al. [44]	Analyze EVT in patients presenting acute anterior circulation AIS-LVO during the pandemic and postepidemic periods.	Retrospective observational	Total patients, total time, and prehospital time were prolonged during the pandemic and post-epidemic periods. There was no difference in procedural time and clinical outcomes.
Zhao et al. [37]	Evaluate the QOL of people with stroke during the pandemic.	Match paired	Physical and mental component scores (PCS and MCS) were higher among the pandemic group than the pre-pandemic group. Pandemic stress, demographic and clinical characteristics were associated with PCS and MSC. Pandemic stress affected stroke patients' QOL, but personal recovery decreased the impacts of pandemic stress.
England		1	
Padmanabhan et al. [84]	Examine the impact of COVID-19 on stroke admissions, treatments, and outcomes.	Retrospective observational	There was a reduction in stroke admissions and arrival times during the pandemic. Rates of thrombolysis and thrombectomy were maintained. A lower number of stroke admissions allowed better service to admitted individuals.
Egypt			

Altschul et al. [45]	Evaluate the impact of the pandemic on ELVO systems of care, treatment, and outcomes.	Retrospective cohort	During the pandemic, there was a decreased rate of thrombolysis and mechanical thrombectomy, and less people presenting with ELVO. There was more delayed admission to the hospital, especially in younger patients who had lower outcomes scores upon admission.
Finland			
Gronroos et al. [46]	Describe case reports of an ultra-fast diagnostic proposal in the settings of AIS in the ED of a primary stroke centre during the pandemic.	Observational	AIS protocol during COVID-19 did not change, the circumstances could change. Patients were triaged and screened for COVID-19 upon arrival; if positive, the patient was treated in a separate cohort area. Examination and treatments were performed with full PPE and laboratory testing and radiology services in a separate CT room.
France			
Gabet et al. [47]	Assess the impact of the COVID-19 pandemic on stroke hospitalization rates, patient characteristics, and case fatality rates.	Observational and cross-sectional	During the lockdown, there was greater in-hospital case fatality rates, and less patients hospitalized for stroke and TIA (and they were more likely to have major stroke symptoms). Patients were more likely to be admitted to stroke care units rather than resuscitation units, and more likely to be quickly transferred to rehabilitation unites after the acute stage of stroke care.
Germany			
Hoyer et al. [50]	Assess and quantify the dynamics of admission for stroke and TIA and rates of reperfusion therapies during the COVID-19 pandemic and to estimate a potential impact of the partial lockdown.	Retrospective cohort	During the pandemic, there was a significant decrease in stroke admission rates for TIA but reperfusion therapy rates remained unaffected. The number of ischemic events was correlated with mobility measures.
Ikenberg et al. [48]	Analyze numbers and patterns of code stroke patients dispatched by	Retrospective	Rates of Code Stroke referrals and thrombolysis and thrombectomy treatments remained stable between the pandemic and pre-pandemic groups. The

			There was a decline in presentation of all stroke subtypes during the pandemic compared to the pre-
	rates during the pandemic.		pandemic period. Provision of acute recanalization treatments was not affected by the pandemic.
India	,		<u> </u>
Sylaja et al. [51]	Identify the challenges in acute stroke care, poststroke rehabilitation, and care of stroke survivors during the pandemic in India and propose mitigating measures.	Observational report	The stroke chain of survival and care pathways were affected by the shortfall of health insurance coverage, inaccessibility of specialized stroke care units, and reduced workforce available for stroke services. There was a reduction in stroke cases, intravenous thrombolysis, and endovascular procedures observed since the lockdown. This decrease was larger than that of the US. The lockdown prevented some timely consultation with caregivers, leading minor stroke diagnoses to be missed. Patients from remote areas were at greatest risk of not reaching hospitals due to the suspension of public transport.
Iran			
Ghoreishi et al. [53]	Examine the changes in stroke epidemiology and care during the COVID-19 pandemic.	Cohort	Stroke hospitalization rates per 100,000 population decreased during the pandemic. Lower admission rates were also observed for patients with mild ischemic stroke.
Tavanaei et al. [52] Israel	Examine the observed decrease in stroke admissions during the COVID-19 pandemic period and explore potential contributing factors at an academic neurology and neurosurgery center.	Retrospective cohort	The pandemic period was associated with the decline in stroke admissions, time from onset to hospital arrival, and outcomes. No substantial changes in the stroke network were found during the pandemic period.

Libruder et al. [54]	Investigate the impact of COVID-19 outbreaks on admission rates and inhospital care for stroke.	Retrospective observational	During the pandemic, there was a significant reduction in hospital admissions. Reperfusion therapy rates and in-hospital care parameters did not change.
Mor et al. [55]	Examine the effect of social distancing on AIS patients' referral to the ED.	Retrospective archive	The percentage of AIS diagnoses fell in 2020 but the number of patients receiving tPA or EVT increased. The rate of patients arriving after symptom onset was highest in 2020.
Saban et al. [56]	Examine the impact of the COVID-19 pandemic on the presentation and care to AIS patients at ED.	Retrospective	During the pandemic, there was a decline in the number of AIS patients admitted to the ED but there was an increase in number of patients who underwent EVT.
Italy			
Asteggiano et al. [58]	Describe the reorganization carried out during the pandemic at one stroke center in Italy.	Retrospective	Adopted measures of self-protection did not affect recanalization time. There was a significant increase in the time between hospital admissions during the pandemic as compared to the same period in 2019 for three reasons: patient's anxiety may have discouraged them from going to the hospital; available ambulances were overloaded dure to COVID-19 emergency; and patients had longer distances to travel to stroke specific hospitals.
Bersano & Pantoni [8]	Discuss the main direct and indirect impacts of COVID-19 on stroke care in Italy.	Observational report	Stroke health professionals were reallocated and many stroke units became designated for COVID-19. Acute stroke patients were met with a lack of services and delays in time-dependent treatment or diagnostics. Insufficient follow-ups and management measures increased the risk of recurrent events or complications.
Brunetti et al. [60]	Evaluate the impact of the pandemic and the lockdown measures on the hub-and-spoke stroke network.	Retrospective observational	During the COVID-19 period, there was a reduction of number of thrombolysis, shorter length of hospitalization, and an increase of pneumonia. There was an increase in onset-to-door time and in door-to-

			groin time. There is no statistically significant interaction between years (2019 vs 2020) and facility of admission (hub vs spoke).
Candelaresi et al. [61]	Analyze the impact of the COVID-19 pandemic and lockdown measures on incidences of stroke.	Retrospective	The global number of patients with acute stroke did not significantly decline from 2019-2020. However, during the lockdown, there was a significant reduction in reperfusion treatments with longer time-to-imaging. Protocols were burdened by protective measures across all phases of stroke care, contributing to delays. Family members were not able to enter hospitals which created delays in obtaining patient history. Distinct pathways were created for suspected or confirmed cases of COVID-19.
Frisullo et al. [57]	Evaluate the impact of lockdown measures on performance indicators of hospital ICP dedicated to ischemic stroke.	Observational cohort	There was a significant increase in ODT indicating that pre-hospital stroke care was related to patient and bystander behaviours and efficacy of the EMS. Psychological factors could have contributed to a "wait-and-see" behavior. This led to many patients missing the time window for IVT and delays in EVT. During the pandemic, there were shorter hospitalization times due to the need to minimize risk of exposure at the hospital and a faster transfer to patients to rehabilitation units.
Mammi et al. [62]	Share experiences of delivering speech-language rehabilitation for stroke inpatients during the COVID-19 outbreak	Observational report	Providing rehabilitation services during the pandemic with a new work routine was feasible, but presented challenges including space, activity, relational, and time limitations. Appropriate interventions were important for patients' functional progress
Manganotti et al. [63]	Examine stroke management during pre-lockdown and lockdown periods.	Retrospective observational	There was a significant decrease in thrombectomy during the lockdown period, while thrombolysis rate was unaffected. Dedicated protected rooms in stroke units for stroke patients' emergencies and specific

Naccarato et al. [64]	Evaluate the effects of COVID-19 pandemics on stroke management.	Retrospective cross-sectional	training for operators helped to maintain the rate of reperfusion therapies. More minor stroke patients were treated at home by general practitioners while severe patients presented to hospitals. There was a significant reduction in total admissions to the Hub Stroke Unit and higher prevalence of
	paraemes on science management.	eross sectional	severe stroke (high NIHSS) during the lockdown as compared to the pre-pandemic period. The structured pathways adopted by the local health system were effective in their prehospital and intrahospital time response.
Paolucci et al. [65]	Evaluate changes in incidence and management of suspected stroke cases in a stroke network.	Retrospective observational	During the pandemic, there was a decrease of stroke cases managed in the ED and no delays in reperfusion therapies. To screen and triage COVID-19-suspected patients, the ED adopted two parallel intra-hospital routes to manage stroke patients safely without affecting the effectiveness of the neurovascular team.
Pero et al. [66]	Characterize the impact of the pandemic on the medical system's responsiveness regarding endovascular treatment for ischaemic stroke.	Retrospective observational	During the pandemic, stroke treatment was delayed, particularly in the first wave, likely due to reallocation of resources and shutting down of spoke centers.
Sacco et al. [67] Japan	Investigate the rate of hospital admissions for cerebrovascular events and of revascularization treatments for AIS during the coronavirus disease 2019 outbreak.	Prospective	Stroke hospitalizations and intravenous thrombolytic treatments decreased possibly due to a delay in hospital arrivals, as a consequence of patient reluctance to come to hospitals during the outbreak. COVID-19 procedures may have caused further delays. Rate of endovascular procedures did not decrease as centralization of patients was and effective strategy to limit the impact on stroke management.

Ota et al. [9]	Assess the number of patients with acute stroke seeking emergency care since the declaration of the state of emergency in the COVID-19 pandemic.	Retrospective and prospective	The number of stroke patients admitted in 2020 decreased when the state of emergency was declared. The ratio of thrombectomy to LVO did not differ. After lifting the state of emergency, the reduced number of outpatient departments and elective operations recovered quickly.
Sakamoto et al. [68]	Examine changes that occurred in stroke patients who had temporary interruption of rehabilitation due to the COVID-19 pandemic.	Observational	Stroke patients had worse functional scores during the pandemic, associated with a disruption to outpatient rehabilitation and resulting inactivity.
Lithuania	•	<u> </u>	
Melaika et al. [69]	Compare stroke care patterns before and during a state-wide lockdown.	Prospective observational	During the lockdown, there was as decrease in stroke alerts, stroke admissions, and prehospital stroke triage quality for patients with referrals for suspected stroke.
Malaysia			
Loh et al. [70]	Compare the admission and outcome variables between pre-pandemic and pandemic phases.	Cross sectional	The number of stroke events remained stable with an increase of recanalization therapies and better inhospital workflow metrics during the pandemic. Time for COVID-19 screening for stroke patients was increased.
Netherlands			
Rinkel et al. [71]	Assess trends in hospital admissions and workflow parameters of acute stroke during the pandemic.	Retrospective cohort	There was a decreased number of patients with suspected stroke presenting in EDs. The proportion of patients who underwent reperfusion therapy and treatment times did not change. Outpatient visits were suspended during the outbreak and non-acute care was done via telephone.
Norway			
Kristoffersen et al. [73]	Investigate how the initial phase of COVID-19 affected hospital stroke management and research.	Prospective	Most neurological departments changed their practice during the initial phase of the COVID-19 pandemic, resulting in a worse standard of care. Hospitals took longer time than usual on thrombolysis assessments,

Thommessen et al. [72] Saudi Arabia	Investigate how the pandemic lockdown the number of admissions of acute stroke.	Retrospective	reduced outpatient clinic activities during lockdowns, post-postponed follow-ups, and limited stroke rehabilitation. There was significant reduction in number of admissions for stroke and TIAs during the lockdown. A large proportion of patients missed the time window for thrombolysis. The ED and stroke unit did not change criteria for stroke admissions and all treatment options were as available as before the lockdown.
Ahmed et al. [74]	Investigate rates of depression and anxiety in stroke patients during the COVID-19 pandemic to improve early psychological interventions for stroke patients during a crisis.	Prospective cross-sectional	Rates of PSD were comparable to the pre-pandemic rates; however, PSA was significantly higher in the pandemic group. Discontinuation of rehabilitation programs had a negative association with PSA but a positive association with PSD. A lack of social support during the pandemic is associated with more depression and anxiety symptoms. Higher post-stroke disability was also correlated with the discontinuation of rehabilitation services due to the pandemic, which was associated with more PSD.
Samkari et al. [75]	Assess the impact COVID-19 had on ischemic stroke admission rate and severity.	Retrospective	There was a reduction in AIS during the pandemic but no significant differences in rate of admission, stroke severity, and rate of thrombolysis before and after the outbreak. The ER was restricted to eligible patients or referrals. There was a reduction in referrals.
Spain		Τ	
Montaner et al. [79]	Evaluate the number of stroke cases attending and treated at a South European region before and during the outbreak.	Retrospective cross-sectional	During the confinement period of the pandemic, stroke unit admissions, number of code stroke, and telestroke consultations declined. Timely acute treatment was also delayed. This was associated with

			the increased in COVID-19 cases that crowded
			hospitals
Riera-Lopez et al. [78]	Examine the impact of COVID-19 on	Retrospective	There was a significant reduction of SC cases during
	SC in the EMS.	observational	the COVID period as compared with the seasonal
		cohort	influenza period but not the same period the year
			before.
Rudilosso et al. [77]	Analyze how the COVID-19	Retrospective	During the pandemic, there were notable reductions
	pandemic affected acute stroke care	_	in Stroke Code activations, stroke admissions, and
	in a CSC.		thrombectomies compared to March 2019. Despite
			these declines, workflow metrics and the rate of good
			clinical outcomes remained comparable to the data
			from 2019. A distinctive observation was that
			patients experiencing strokes during the pandemic
			were notably younger, suggesting that older
			individuals might have been more hesitant to seek
			emergency assistance due to fears of contracting
			COVID-19.
Tejada Meza et al. [76]	Analyze the impact of the COVID-19	Retrospective	There was a decrease in admissions for ischemic
3	pandemic on reperfusion therapies for	observational	stroke and reperfusion therapies during the pandemic.
	stroke.		There was an increase in detection of symptoms-to-
			door time and door-to-puncture time for reperfusion.
Switzerland			
Altersberger et al. [80]	Investigate if the COVID-19	Prospective cohort	During the lockdown, the number of patients treated
	pandemic lockdown affected acute		with acute reperfusion therapy was lower compared
	stroke care service.		with the reference period in centers with severe
			lockdown but not in centers with mild lockdowns.
			Pre-hospital and in-hospital time-based performance
			measures, short-term clinical and safety outcomes did
			not change significantly.
Taiwan			
Chen et al. [81]	Investigate the effects of a nationwide	Retrospective	There was a trend towards less daily stroke
	collaborative model to improve		admissions as there were more COVID-19 cases. The
	_		quality metrics during the pandemic were

United Kingdom (not specified)		D. d.	comparable to the 2019 period and there was improvement in rehabilitation evaluation and stroke education.
Kwan et al. [83]	Examine the impact of COVID-19 on stroke thrombectomy services.	Retrospective	During the pandemic, stroke admissions decreased but thrombectomy and successful recanalization rate were maintained. Time metrics and early neurological outcomes did not significantly change. There was a drop in external stroke thrombectomy referrals despite the referring hospitals being instructed to continue referring as before.
United States			
Agarwal et al. [20]	Describe experiences of providing acute stroke care at a CSC and compare time metrics for receiving thrombolysis or mechanical thrombectomy to a pre-pandemic cohort.	Retrospective	There were no significant group differences in stroke time metrics and "defect-free care" (treatment within stroke quality recommended time limits). Patients treated during the pandemic had worse discharge outcomes and increased mortality. There was a lower volume of AIS admissions during the pandemic and less thrombolysis and MT were performed.
Balucani et al. [86]	Examine the impact of the COVID-19 pandemic on stroke admissions and stroke care.	Retrospective	During the pandemic, there were decreased stroke admissions and thrombolysis treatments, and increased 'last know well' to hospital arrival. Rates of thrombectomies were unchanged.
Cummings et al. [87]	Investigate the trends in telestroke consults during the pandemic.	Retrospective and prospective	Weekly telestroke consults dropped during the pandemic. There were no differences in baseline features, however, black patients were less likely to present with strokes during the pandemic. There was a higher rate of tPA administered to black patients during the pandemic compared with before.
de Havenon et al. [89]	Provide descriptive statistics for stroke and ACS during and before COVID-19.	Retrospective	There was a significant decrease in the number of stroke patients discharged from hospitals and volume of tPa for AIS during the pandemic period as

de Havenon et al. [88]	Assess hospital discharge rates and outcomes of ischemic stroke patients during the pandemic.	Retrospective cohort	compared to the same time at different years. However, there was only a mild decrease in MT for AIS. The mean number of discharges began decreasing in Feb. 2020 but returned to pre-pandemic levels by Jul. 2020. Black and Hispanic patients accounted for
			more of those discharged with ischemic stroke and comorbid COVID-19.
Desai et al. [24]	Understand the impact of the COVID-19 pandemic on the utilization of stroke emergency services on a CSC.	Retrospective	Number of total ED encounters, acute ischemic strokes, and TIAs decreased between March of 2017–2019 compared to March of 2020. The number of patients undergoing EVT in March 2020 was comparable to March 2017–2019.
Etherton et al. [90]	Determine the effect of the pandemic on patterns of stroke patient presentation and quality of care.	Retrospective	During the pandemic, there were reduced quality of care metrics, telestroke consults, and ischemic stroke admissions. There were no changes in patient presentation or timeliness of in-hospital stroke evaluation and treatment. Thrombectomy rates and clinical severity did not change.
Greenwood et al. [91]	Determine the impact of COVID-19 safety protocols on the management of an acute stroke.	Retrospective	Pandemic restrictions lowered volume of stroke alerts, mostly driven by a decrease in mild stroke patients. Stroke severity at admission was significantly higher in the pandemic group. There was a significant increase in probability of patients receiving stroke treatment (thrombolytics; mechanical reperfusion). The risk of COVID-19 contraction in-hospital was low.
Huang et al. [92]	Describe the effects of the pandemic on telestroke service lines 30 days before and after the pandemic's declaration.	Cross-sectional	There was a decrease in telestroke utilization during the pandemic. The time from symptom onset to telestroke activation decreased.
Jillella et al. [93]	Investigate whether the COVID-19 pandemic led to a delay in	Observational cohort	Longer treatment delays were observed during COVID-19 and were associated with higher in-

	intravenous thrombolysis (IVT) among stroke patients.		hospital death/hospice discharge irrespective of admission period.
Nogueira et al. [94]	Evaluate the impact of COVID-19 in screening for acute stroke utilizing an artificial intelligence (AI) platform.	Prospective	There was a decrease of stroke imaging during the pandemic and more delayed hospital arrival times.
Rameez et al. [95]	Examine the impact of the stay-at- home order on stroke admission, subtype, and metrics during the pandemic.	Retrospective	Following stay-at-home orders, there was an increase in hemorrhagic stroke, and decrease in AIS. There was a delay in ED arrivals and increase in number of younger stroke patients.
Schirmer et al. [96]	Analyze the impact of the pandemic on the timing and presentation of acute ischemic stroke patients and the association between delays and pandemic-related limitations.	Retrospective	There was no significant difference between the severity of stroke presentation (NIHSS score) of the groups. The COVID-period saw higher a time interval between LKW to presentation as compared to the Baseline period but did not see an age difference. Delay in presentation may be linked to patients' perceived concerns or outright fear of interacting with the health-care system during a pandemic.
Sharma et al. [97]	Investigate a decline in admissions for stroke and TIA/stroke, and ED stroke alert activations.	Retrospective	There was a decline in hospital admission that coincide with the stay-at-home recommendations. ED stroke alerts declined. Social distancing practices may have led to lack of contact with others and under-reporting symptoms.
Siegler et al. [98]	Confirm whether anecdotal reports that stroke admission rates may decline due to the pandemic are supported by prospective observations.	Exploratory analysis	During the pandemic period, there was a fall in new stroke diagnoses in comparison to the period before March. 1st, 2020. This related to the fall in number of daily transfers from referral centers, telestroke consultations, and hospital presentations through emergency services. The severity of stroke was greater during the COVID-19 period than the months preceding it. A reduction in the utilization of MRI during the pandemic may have contributed to the lower stroke rate observed.

Siegler et al. [99]	Evaluate the effect of the COVID-19 pandemic on systems of care in the management of acute stroke.	Retrospective observational	Evaluation for AIS during the pandemic was associated with a delay in thrombolysis but not thrombectomy time metrics. There were delays in imaging to treatment initiation.
Srivastava et al. [100]	Analyze the characteristics, evaluation, treatment, and in-hospital outcomes of stroke patients during the pandemic.	Retrospective observational	Stroke presentations decreased during the COVID-19 period, but rates of intervention, computed tomography, and time metrics were maintained.
Tabibian et al. [101]	Evaluate the effects of a new thrombectomy protocol during the pandemic.	Retrospective cohort	After activation of an adaptive code stroke protocol during the pandemic, there were no significant differences in recanalization rates but worse stroke outcomes.
Thau et al. [102]	Evaluate discharge planning and long-term outcomes of stroke patients treated during the COVID-19 pandemic who were recommended for discharge to inpatient rehabilitation.	Retrospective observational	During the pandemic, there was an increase in discharge disability and decrease in discharges to inpatient rehabilitation.
Tong et al. [103]	Examine rates of stroke hospitalization and adherence to stroke quality-of-care measures during the pandemic.	Retrospective	During the COVID-19 period, there was a reduction in stroke hospitalizations with stroke severity being higher. Rates of defect-free care and stroke education delivery were not affected by the pandemic.
Velasco et al. [104]	Investigate the impact of the pandemic on acute stroke care at a nonurban medical centre without widespread community transmission.	Retrospective and prospective	During the pandemic, there was a decrease in transports to the ED. The interval between EMS dispatch to ED arrival for stroke patients was significantly longer in the pandemic period. Volumes of IV thrombolysis, DTN times, and short-term outcomes were similar.

Chowdhury et al. [35]	Gather and summarize information	Cross-sectional	The number of AIS patients and EVT cases
	from tertiary care stroke centers	study	decreased during the pandemic. Most centers had a
	during the COVID-19 pandemic.		dedicated stroke team and modified protocols for
			managing AIS. Most centers did not alter anesthetic
			management plans.
England, Wales & North Ireland			
Douiri et al. [82]	Describe the impact of the initial	Prospective cohort	There was a drastic reduction in patients presenting
	wave of the pandemic on		to hospitals with stroke during the pandemic,
	administrations, care quality, and		especially for older patients and for ischemic stroke.
	outcomes of stroke patients.		Prehospital routing protocols were not implemented
			country wide. There were no changes in stroke triage
			policies in hospitals. Quality of care was preserved
			and even improved during lockdown.
Italy, France & Germany			

Bersano et al. [59] United States & Germany	Report the experiences of stroke neurologists from three European countries.	Observational report	The prioritization of COVID-19 patients and units resulted in reorganization of pre-hospital transportation, limited consultations with stroke physicians and neurologists, centralization of stroke centres and rehabilitation pathways, reduced availability of ancillary examinations, timely therapies, and emergency pathways for stroke patients. The reorganization in pathways led to consequences in delays, use of acute treatment, and prognosis. There was a reduction of hospitalization for stroke and stroke acute therapies in comparison to the same period in 2019. Fear of in-hospital infection and the advice from health authorities and the media likely contributed to the reluctance to seek when people experienced mild symptoms. The government lockdown measures led to stroke symptoms in individuals being missed by others.
Al Kasab et al. [85]	Evaluate the impact of the pandemic on racial disparities among stroke patients receiving MT.	Prospective study	Patients who presented during the pandemic required a longer procedure time and had a higher rate of mortality. During the pandemic, there was a reduction in the number of African Americans undergoing MT.
