## **ABSTRACT:**

### **Background and Objectives:**

*TMEM106B* has been proposed as a modifier of disease risk in FTLT-DTP, particularly in *GRN* mutation carriers. Furthermore, *TMEM106B* has been investigated as a disease modifier in the context of healthy aging and across multiple neurodegenerative diseases. The objective of this study is to evaluate and compare the effect of *TMEM106B* on gray matter volume and cognition in each of the common genetic FTD groups and in sporadic FTD patients.

### **Methods:**

Participants were enrolled through the ARTFL/LEFFTDS Longitudinal Frontotemporal Lobar Degeneration (ALLFTD) study, which includes symptomatic and presymptomatic individuals with a pathogenic mutation in *C9orf72*, *GRN*, *MAPT*, *VCP*, *TBK1*, *TARDBP*, symptomatic non-mutation carriers, and non-carrier family controls. All participants were genotyped for the *TMEM106B* rs1990622 SNP. Cross-sectionally, linear mixed-effects models were fitted to assess an association between *TMEM106B* and genetic group interaction with each outcome measure (gray matter volume and UDS3-EF for cognition), adjusting for education, age, sex and CDR®+NACC-FTLD sum of boxes. Subsequently, associations between *TMEM106B* and each outcome measure were investigated within the genetic group. For longitudinal modeling, linear mixed-effects models with time by *TMEM106B* predictor interactions were fitted.

### **Results:**

The minor allele of *TMEM106B* rs1990622, linked to a decreased risk of FTD, associated with greater gray matter volume in *GRN* mutation carriers under the recessive dosage model. This was most pronounced in the thalamus in the left hemisphere, with a retained association when considering presymptomatic *GRN* mutation carriers only. The minor allele of *TMEM106B* rs1990622 also associated with greater cognitive scores among all *C9orf72* mutation carriers and in presymptomatic *C9orf72* mutation carriers, under the recessive dosage model.

### **Discussion:**

We identified associations of *TMEM106B* with gray matter volume and cognition in the presence of *GRN* and *C9orf72* mutations. This further supports *TMEM106B* as modifier of TDP-43 pathology. The association of *TMEM106B* with outcomes of interest in presymptomatic *GRN* and *C9orf72* mutation carriers could additionally reflect *TMEM106B*'s impact on divergent pathophysiological changes before the appearance of clinical symptoms.

## INTRODUCTION

Frontotemporal lobar degeneration (FTLD) is one of the leading causes of dementia in individuals younger than 65 years and represents 10-20% of all dementias. The term frontotemporal dementia (FTD) is used as an umbrella term for the spectrum of clinical manifestations that may result from FTLD, such as progressive changes in behavior or language difficulties. Some patients may also develop amyotrophic lateral sclerosis (ALS) or parkinsonism. One-third of patients show a strong family history, with most common genetic causes of FTD being autosomal dominant mutations in the progranulin (*GRN*) gene<sup>1,2</sup>, the microtubule-associated protein tau (*MAPT*) gene<sup>3</sup> and the chromosome 9 open reading frame 72 (*C9orf72*) gene<sup>4</sup>.

Apart from autosomal dominant mutations causing FTD, additional genetic risk factors have been identified. In a genome-wide association study (GWAS) for the subgroup of FTLD patients characterized by TDP-43 pathology (FTLD-TDP), *TMEM106B* was identified as a risk factor<sup>5</sup>. The major allele (A) of the lead variant in the *TMEM106B* locus (rs1990622) was associated with an increased risk for developing disease. Interestingly, the association with *TMEM106B* was most pronounced in the subset of FTLD-TDP patients carrying a *GRN* mutation<sup>5</sup>, implying that disease risk imposed by autosomal dominant mutations is also subject to genetic modifiers. In a GWAS of symptomatic *GRN* cases versus population controls, individuals carrying the minor *TMEM106B* haplotype indeed showed a 50% lower chance of developing disease symptoms as compared to *GRN* mutation carriers without the minor *TMEM106B* haplotype<sup>6</sup>. Several other reports support the reduced disease penetrance associated with the minor (protective) *TMEM106B* haplotype<sup>7</sup>, in particular in patients with *GRN* mutations<sup>8,9</sup>. Strikingly, an obligate *GRN* mutation carrier was still unaffected in their 80's, and found to be a homozygous carrier of the minor *TMEM106B* haplotype<sup>10</sup>. This suggests that carrying two copies of the *TMEM106B* minor allele may counteract the disease-causing effects of the *GRN* pathogenic mutation. A protective effect of the minor allele of *TMEM106B* rs1990622 SNP has also been demonstrated in *C9orf72* repeat expansion carriers, though less prominent compared with *GRN* mutation carriers<sup>11</sup>. While this has implications for genetic counselling, genotyping *TMEM106B* in *GRN* mutation carriers in the diagnostic setting is not routinely being performed.

*TMEM106B* has also been investigated as a disease modifier in the context of healthy aging. In elderly adults, the major risk allele of rs1990622 is associated with a smaller volume of the superior temporal gyrus, especially in the left hemisphere<sup>12</sup>, with more advanced TDP-43 pathology at autopsy<sup>13</sup>, increased biological aging in the prefrontal cortex<sup>14</sup>, worse cognitive function<sup>14</sup> and decreased neuronal proportion<sup>15</sup>. Moreover, in patients with FTD carrying two copies of the risk allele (AA) compared with the (AG+GG) group, lower cortical gray matter volumes in the frontal, temporal, cingulate and insula cortices were noted<sup>16</sup>. *TMEM106B* has also been shown to be a modulator of gray matter volume and functional network connectivity in presymptomatic mutation carriers<sup>17-19</sup>, and of

cognitive trajectories over time among clinical FTD patients<sup>20</sup>. However, associations of *TMEM106B* with structural imaging and cognition within different FTD genetic groups remains to be investigated. Beyond FTLD, *TMEM106B* has been implicated in TDP-43 pathology in Alzheimer's disease (AD)<sup>21</sup>, cognition in Parkinson's disease (PD)<sup>20</sup> and ALS, though with conflicting findings in terms of directionality of effects in ALS<sup>22,23</sup>.

In this study, we aimed to investigate the modifying effects of *TMEM106B* in the largest collection of systematically ascertained FTD patients and families from the ARTFL/LEFFTDS Longitudinal Frontotemporal Lobar Degeneration (ALLFTD) study, on gray matter volume and cognitive measures. Understanding the modifying effects of *TMEM106B* across genetic FTD subtypes is crucial in light of genetic counselling and the development of gene-based therapies.

## MATERIAL AND METHODS

### Study participants and genetic analysis

Participants were enrolled through Advancing Research and Treatment for Frontotemporal Lobar Degeneration (ARTFL, NCT02365922) and Longitudinal Evaluation of Familial Frontotemporal Dementia Subjects (LEFFTDS, NCT02372773)<sup>24</sup> which combined into the ARTFL/LEFFTDS Longitudinal Frontotemporal Lobar Degeneration (ALLFTD, NCT04363684) study. These studies enrolled participants through a consortium of 27 centers across the US and Canada between 2015 and 2023. Here, we report data from the most recent study visits for each participant as of October 26, 2023. This study involves human participants and was approved by Johns Hopkins Medicine Institutional Review Board (IRB) serving as the single IRB for the ALLFTD Consortium (CR00042454/IRB00227492). All participants provided written informed consent or assent with proxy consent.

ALLFTD participants had genetic testing at the University of California, Los Angeles using published methods<sup>25</sup> . Briefly, DNA samples were screened for genes previously implicated in neurodegenerative diseases, including *GRN*, *MAPT*, *TBKI*, *VCP*, *TARDBP*, using targeted sequencing or whole-exome sequencing. The presence of hexanucleotide repeat expansions in *C9orf72* was detected using both fluorescent and repeat-primed PCR. *TMEM106B* rs1990622 genotyping was carried out by real-time PCR on a LightCycler® 480 System using Taqman SNP Genotyping Assays (#C\_\_11171598\_20). Assays were run in duplicate.

Genome-wide SNP genotyping data from 1,975 ALLFTD participants was used to perform lineage analysis using PLINK. Briefly, QC was performed to remove individuals with low call rate and filter autosomal SNPs for missingness, frequency, and deviation from Hardy-Weinberg equilibrium. Genetic ancestry was inferred by projecting genotyped samples into the principal components of the 1000 Genomes reference panel, using R package bigsnpr. Identity-by-descent (IBD) estimates were then calculated to determine relatedness, followed by family-network identification and pedigree reconstruction using PRIMUS<sup>26</sup>.

After additional filtering on the availability of clinical data (clinical phenotype, age at visit) and genetic data (mutation in *C9orf72*, *GRN*, *MAPT*, *VCP*, *TBKI*, *TARDBP* or non-carrier) a total of 1,798 individuals were retained (**Table 1**). For affected non-mutation carriers, we only retained those with an FTD spectrum disorder, defined as either behavioral variant FTD (bvFTD), FTD with amyotrophic lateral sclerosis (FTD-ALS), corticobasal syndrome (CBS), progressive supranuclear palsy (PSP), agrammatic/nonfluent primary progressive aphasia (nfvPPA) or semantic variant PPA (svPPA).

## Data collection of outcome measures

### Neuroimaging outcome: gray matter volume

Image acquisition and processing were conducted as described previously<sup>27</sup>. Before any preprocessing of the images, all T1-weighted images were visually inspected for quality control. Images with excessive motion or image artifact were excluded. T1-weighted images underwent bias field correction using the N3 algorithm<sup>28</sup>. The segmentation was performed using SPM12 (Wellcome Trust Center for Neuroimaging, London, UK, <http://www.fil.ion.ucl.ac.uk/spm>) unified segmentation<sup>29</sup>. A customized group template was generated from the segmented gray and white matter tissues and cerebrospinal fluid by non-linear registration template generation using the Large Deformation Diffeomorphic Metric Mapping framework<sup>30</sup>. Subjects' native space gray and white matter were geometrically normalized to the group template, modulated, and then smoothed in the group template. The applied smoothing used a Gaussian kernel with 8~mm full width half maximum. Every step of the transformation was carefully inspected from the native space to the group template. Regional volume estimates were calculated from individual subjects' smoothed, modulated gray matter in template space, by taking the mean of all voxels in several *a priori* regions of interest (ROIs)<sup>31</sup>. The ROIs are summarized in **eTable 1**. All measures were expressed as a percentage of total intracranial volume. For gray matter volumetric measures, data was available for 958 participants (**eTable 2**).

### Cognitive outcome

Cognition was defined using the National Alzheimer's Coordinating Center Uniform Data Set (v3.0) executive function composite score (UDS3-EF), as described previously<sup>32,33</sup>. The UDS3-EF is an item response theory-based composite derived from 7 total UDS3-EF test scores: category fluency (animals and vegetables; total correct), lexical fluency (F and L words; total correct), number span backward (total correct trials), Trail Making Test parts A and B (correct lines per minute). The cognitive domains that factor into the UDS3-EF score (e.g., mental set-shifting, verbal fluency, attention/working memory) support the potential utility as a single composite measure of the common cognitive changes observed across a range of clinical phenotypes in FTD spectrum patients. The UDS3-EF composite score was available for 1,581 participants (**eTable 3**).

### Neurofilament light chain concentrations

Plasma neurofilament concentrations were determined as described previously<sup>34,35</sup>. Venous blood was collected in ethylenediaminetetraacetic acid-containing tubes. Blood was centrifuged at 1500 g and 4 °C for 15 minutes. Plasma samples were aliquoted in 1000- $\mu$ L polypropylene tubes and stored at -80 °C, until further use. Samples (1 thaw only) were gradually brought to room temperature before analysis. Neurofilament light chain (NfL) concentrations were quantified in duplicate using the

ultrasensitive HDX analyzer by single-molecule array (Simoa) technology (Quanterix) by investigators blinded to clinical group allocation.

## Statistical analysis.

All analyses were conducted in R (version 4.2.2). Linear mixed effects analyses were conducted with the function ‘lmer’ in the R package ‘lme4’ (version 1.1.31).

For all cross-sectional analyses, the last available visit with the outcome measure available was used. Linear mixed models were fitted for the assessment of the main effect of the genetic groups according to their affection status (symptomatic/asymptomatic) on outcome variables, with individuals grouped by genetic status and affection status (**eTable 4**), with education, sex, age at visit and CDR®+NACC-FTLD sum of boxes score as fixed covariates and pedigree as random effect. Due to sample size limitations (< 10), only non-mutation carriers and individuals with a mutation in *C9orf72*, *GRN* or *MAPT* were considered.

To investigate the effect of the *TMEM106B* rs1990622 genotype on gray matter volume and cognition, linear mixed models were fitted with education, age, sex, genetic status and the CDR®+NACC-FTLD sum of boxes as covariates. The statistical analyses were performed under an additive (AA vs. AG vs. GG) and recessive [(AA+AG) vs. GG] genetic model, where A and G are the major and minor allele, respectively. Secondary subgroup analyses were conducted in affected individuals only, a participant was defined as affected when the primary clinical phenotype was different from ‘clinically normal’.

In addition, the effect of *TMEM106B* genotype on gray matter volume and cognition was assessed in linear mixed effect models with interaction testing between the *TMEM106B* genotype and genetic group (non-carrier, *GRN*, *MAPT* or *C9orf72*). If  $p < 0.05$  for the interaction term *TMEM106B*\*genetic group, linear mixed models were fitted for the individuals belonging to that genetic group respectively (subgroup analyses), with education, age at visit, sex and CDR®+ NACC-FTLD sum of boxes as covariate.

In longitudinal models, we used linear mixed effects models with random slopes and intercepts [(time since baseline | participant ID) + (1 | pedigree ID)] to evaluate the association between *TMEM106B* genotype dosage and longitudinal changes in gray matter volume and cognition. Each participant’s baseline was defined as the first study visit with available imaging and cognitive data. Only participants with at least two timepoints and with at least one visit with a clinical phenotype different from clinically normal were included. To determine whether *TMEM106B* genotype dosages were associated with rates of change in clinical outcomes, we examined the interaction between *TMEM106B* genotype dosage and time since baseline visit, adjusting for baseline age, sex, education

and baseline CDR®+NACC-FTLD sum of boxes. In addition, each genetic group was analyzed in separate models.

For the analyses with the gray matter volumes as outcome, the primary analysis was conducted with the total gray matter volume as outcome. If  $p < 0.05$  for the association of *TMEM106B* genotype with total gray matter volume, secondary analyses with the individual ROIs were conducted. Sensitivity analyses were conducted excluding individuals with non-European ancestry.

## **Data availability**

De-identified human/patient clinical, demographic, imaging and plasma NFL data are available from ALLFTD upon request. Investigators are required to complete the Request Clinical Data form on the request portal (<https://www.allftd.org/data>) and to review the data sharing and publication policy. Data that could identify a participant are not provided. Any additional information required to reanalyze the data reported in this paper is available from the lead contact and ALLFTD.

## RESULTS

### Association of genetic group and affection status with gray matter volume and cognition

First, we investigated the association between the gene-affection status (combined mutation and affection status) and our outcomes of interest: total gray matter volume and cognition (defined by UDS3-EF composite score), adjusting for education, age at visit, sex, CDR®+NACC-FTLD sum of boxes. As expected, being symptomatic, regardless of genetic status, was associated with lower total gray matter volumes and lower UDS3-EF scores (**eTable 5**). In addition, being a presymptomatic *C9orf72* mutation carrier was associated with lower total gray matter volumes (beta = -1.99, 95% CI [-2.80,-1.19],  $p = 1.68 \times 10^{-6}$ ) compared to clinically normal non-mutation carriers (**eTable 5**).

### Association of *TMEM106B* rs1990622 with gray matter volume

Next, we investigated the association between *TMEM106B* rs1990622 and total gray matter volume in the complete cohort, including sporadic and genetic FTD patients, presymptomatic carriers and non-mutation carrier controls. In linear mixed models with genetic status, years of education, sex, age at visit and CDR®+ NACC-FTLD sum of boxes score as fixed covariates and pedigree as random effect, *TMEM106B* rs1990622 did not statistically associate with total gray matter volume with our sample sizes, neither in the additive dosage model nor in the recessive model (**eTable 6**). In subgroup analyses in all affected individuals, including sporadic and genetic FTD, *TMEM106B* rs1990622 did also not statistically associate with total gray matter volume (**eTable 7**) ( $p > 0.05$ ).

Fitting the linear mixed-interaction model between *TMEM106B* rs1990622 and genetic group (non-mutation carrier, *GRN*, *MAPT* or *C9orf72*), with fixed covariates: years of education, sex, age at visit and CDR®+NACC-FTLD sum of boxes and with pedigree as random effect, a protective effect of the minor allele of *TMEM106B* rs1990622 on total gray matter volume was observed with additive and recessive *TMEM106B* dosages in interaction analyses with *GRN* (**Table 2**). In both the additive and recessive model, statistically significant protective effects on the gray matter volumes of the right caudal anterior cingulate, right cerebellum, left rostral caudal anterior cingulate and left frontal cortex were observed (**Table 3**). In the recessive model, the most significantly associated region was the left thalamus ( $p < 9.05 \times 10^{-5}$ , **Table 3**).

In subgroup analyses in *GRN* mutation carriers, *TMEM106B* remained associated with the total gray matter volume in the recessive model (beta = 3.25, 95% CI [0.37,6.19],  $p = 0.034$ ), with the left thalamic region as individual region of interest with the highest association (beta = 0.03, 95% CI [0.01-0.060],  $p = 0.006$ ) (**eTable 8**). Excluding the non-European *GRN* mutation carriers, *TMEM106B*

remained associated with the total gray matter volume and left thalamic gray matter volume (beta = 3.44, 95% CI [0.72, 6.23],  $p = 0.018$  and beta = 0.03, 95% CI [0.01, 0.06],  $p = 0.006$ , respectively).

*GRN* mutation carriers with the *TMEM106B* rs1990622\*GG genotype are presymptomatic mutation carriers (**Figure 1**). Therefore, exploratory analyses were conducted that include only presymptomatic *GRN* mutation carriers. *TMEM106B* remained associated with the total gray matter volume (beta = 3.20, 95% CI [0.80,5.68],  $p = 0.016$ ) and left thalamic gray matter volume (beta = 0.03, 95% CI [0.01,0.05],  $p = 0.003$ ) in presymptomatic *GRN* mutation carriers in the recessive model after controlling for years of education, sex and age at visit (**eTable 9**). Excluding the non-European *GRN* presymptomatic individual did not materially affect the findings with observed estimates of beta = 3.16, 95% CI [0.73, 5.68],  $p = 0.018$  and beta = 0.03, 95% CI [0.01, 0.05],  $p = 0.003$  for the total gray matter volume and left thalamic gray matter volume respectively.

The mean age of onset of the affected *GRN* mutation carriers in our total cohort with bvFTD, CBS or PPA as primary diagnosis is  $59.23 \pm 9.23$  years old. The presymptomatic *GRN* mutation carriers that carry the *TMEM106B* rs1990622\*GG genotype are 29, 45, 49 and 68 years old at their last visit. NfL levels were available for the presymptomatic *GRN* mutation carriers with *TMEM106B* rs1990622\*GG with an age at visit of 29 and 68 years old, respectively. **Figure 2** depicts the age at visit and NfL levels for all *GRN* mutation carriers with NfL levels available at the time of imaging. Visually, it can be observed that the presymptomatic *GRN* mutation carrier with *TMEM106B* rs1990622\*GG genotype with a current age of 68 years had among the lowest NfL levels (7.967 pg/mL), compared with both symptomatic (mean = 61.250 pg/mL) and presymptomatic *TMEM106B* rs1990622\*AA and rs1990622\*AG genotype *GRN* mutation carriers (mean = 24.774 pg/mL) within the same age range (65-77 year).

Longitudinally, the analyses were conducted with the additive model for *TMEM106B* rs1990622 in affected *GRN* mutation carriers. Statistical analyses were conducted for comparison of the rs1990622\*AA group versus rs1990622\*AG in affected *GRN* mutation carriers. We found no differences in the rate of decline in total gray matter volume across rs1990622\*AG carriers versus rs1990622\*AA carriers (beta = 0.536, 95% CI [-1.25, 2.19],  $p = 0.526$ ).

### **Association of *TMEM106B* rs1990622 with cognition**

In linear mixed models with genetic status, years of education, sex, age at visit and CDR®+ NACC-FTLD sum of boxes score as fixed covariates and pedigree as random effect, *TMEM106B* rs1990622 did not statistically associate with UDS3-EF across the complete cohort, neither in the additive dosage model nor in the recessive model (**eTable 6**), or in subgroup analyses in all affected individuals (**eTable 7**).

Fitting the linear mixed-interaction model between *TMEM106B* rs1990622 and genetic group (non-mutation carrier, *GRN*, *MAPT* or *C9orf72*), with as fixed covariates years of education, sex, age at visit and CDR@+NACC-FTLD sum of boxes and with pedigree as random effect, an effect of *TMEM106B* rs1990622 on UDS3-EF score in *C9orf72* mutation carriers was observed with recessive *TMEM106B* dosages (**Table 4**).

In subgroup analyses in *C9orf72* mutation carriers, *TMEM106B* remained associated with UDS3-EF in the recessive model (beta = 0.36, 95% CI [0.05,0.66],  $p = 0.021$ ), and in subgroup analyses in presymptomatic *C9orf72* mutation carriers (beta = 0.33, 95% CI [0.03,0.63],  $p = 0.036$ ). Similar estimates were obtained upon conducting sensitivity analyses in *C9orf72* mutation carriers of European ancestry only (beta = 0.40, 95% CI [0.09, 0.70],  $p = 0.011$ ) and presymptomatic *C9orf72* mutation carriers of European ancestry only (beta = 0.40, 95% CI [0.10, 0.71],  $p = 0.011$ ). In symptomatic *C9orf72* mutation carriers, there was no effect of *TMEM106B* on UDS3-EF (beta = 0.31, 95% CI [-0.19,0.81],  $p = 0.232$ ).

We did not identify statistically significant longitudinal trajectory differences according to *TMEM106B* genotype group (data not shown). In presymptomatic *C9orf72* mutation carriers with at least 2 visits there was no significant decline in cognitive trajectory over time. However, taking into account all the longitudinally collected visits in presymptomatic *C9orf72* mutation carriers, we found in both the additive (beta = 0.22, 95% CI [0.05, 0.39],  $p = 0.014$ ) and recessive (beta = 0.45, 95% CI [0.13, 0.78],  $p = 0.008$ ) model (**eTable 10**), that the minor allele of *TMEM106B* rs1990622 is associated with an increased UDS3-EF score, in line with the cross-sectional data taking only the last visit into account.

## DISCUSSION

*TMEM106B* was initially identified as genetic risk factor for FTLD-TDP. Since then, it has been shown to not only act as modifier of disease penetrance in FTLD-TDP but also as modifier of pathological, imaging and clinical characteristics of FTD and related neurodegenerative diseases. To further confirm the association of *TMEM106B* SNPs with imaging and clinical characteristics in FTD and to evaluate its role in the different genetic groups of autosomal dominant FTD we performed association analyses in the largest available systematically ascertained cohort of FTD patients.

In our complete cohort with imaging data available, no significant association of gray matter brain volumes with *TMEM106B* were detected. However, in *GRN* mutation carriers, carrying two copies of the minor allele of *TMEM106B* was associated with a larger total gray matter volume. This was most pronounced in the thalamus in the left hemisphere, a finding that remained in a subgroup of presymptomatic *GRN* mutation carriers. Thalamic atrophy is a common feature in frontotemporal dementia, and especially in *GRN* mutation carriers, asymmetry in thalamic volumes is apparent<sup>36</sup>. Furthermore, *GRN* presymptomatic mutation carriers display changes in intrinsic connectivity networks, with the thalamus as key hub<sup>37</sup>. This is in line with findings in mice with homozygous *GRN* deletions (*GRN*<sup>-/-</sup>)<sup>38</sup>, where microglial activation in the ventral thalamus drives neurodegeneration in the thalamocortical circuit<sup>38</sup>. Interestingly, patients with FTLD-*GRN* and *GRN*<sup>-/-</sup> mice show similar transcriptomic and histopathological changes in the thalamus, not only in microglia but also in astrocytes, promoting neurodegeneration<sup>39</sup>. Other regions that appear altered in response to *TMEM106B* are the frontal, temporal, parietal, anterior cingulate areas, insula and cerebellum, in line with known patterns of atrophy described in *GRN* mutation carriers<sup>40-42</sup> and in patients with FTLD-TDP type A, the pathology uniformly present in patients with *GRN* mutations. In addition, previous research showed an effect of *TMEM106B* in these regions in a clinically diagnosed FTD cohort<sup>16</sup>.

Importantly, the *GRN* mutation carriers with two copies of the minor allele of *TMEM106B* were all presymptomatic at time of imaging. With a mean age of onset of 59 years in affected *GRN* mutation carriers in our total cohort, it cannot be excluded that these presymptomatic *GRN* mutation carriers will still develop FTD at a later age; however, one of these presymptomatic *GRN* mutation carriers remained without symptoms at 68 years of age. The strikingly low NfL level of this participant compared to *GRN* mutation carriers within the same age range (65-76 years), also well below the mean value of phenoconverters<sup>43</sup>, supports the hypothesis that carrying two copies of the minor allele of *TMEM106B* might offer protection against developing FTD, or at a minimum a delay in disease onset.

In *C9orf72* we did not observe an association between *TMEM106B* and (sub)cortical atrophy. In fact, at the presymptomatic stage, we found that irrespective of the *TMEM106B* genotype, the presence of

*C9orf72* is associated with lower gray matter volumes in comparison to clinically normal non-mutation carriers, consistent with prior work showing structural brain changes occurring 10 to 40 years before onset<sup>27,40,44</sup>. In *GRN* mutation carriers, on the other hand, changes in brain volume occur only within a few years proximity to onset of symptomatic FTD<sup>27,41,42,44</sup>. Moreover, while the rate of volume loss differs between *C9orf72* and *GRN*, with attenuated atrophy rate after onset of symptomatic FTD in *C9orf72* and with an acceleration of atrophy rate after onset in *GRN*, their rate of functional decline is similar<sup>42</sup>. Hence, there might be earlier and divergent pathophysiological changes in *C9orf72* as compared to *GRN* mutation carriers in the presymptomatic phase, with the early loss of gray matter volume in *C9orf72* mutation carriers masking a potential effect of *TMEM106B*.

Contrary to structural imaging, we did identify a protective effect of the *TMEM106B* rs1990622 minor allele on cognition in *C9orf72*, especially in presymptomatic *C9orf72* mutation carriers. With participants with a *C9orf72* repeat expansion already showing signs of neurodegeneration (e.g. gray matter loss) prior to symptom onset, we hypothesize that *TMEM106B* is able to modulate the resilience against developing clinical FTD during these early stages of disease. In support of this hypothesis, homozygosity for the minor allele has been shown to protect *C9orf72* carriers from developing FTD but not from developing ALS<sup>11</sup>. Moreover, discordance between the presence of disease pathology and effects on cognition in the aging population is a known phenomenon and *TMEM106B* has been suggested as a potential modifier of this ‘cognitive resilience’, with the minor allele of *TMEM106B* rs1990622 being associated with a better performance than expected based on pathological burden<sup>45</sup>.

Previous studies focusing on presymptomatic genetic FTD have identified modulating effects of *TMEM106B* genotype on gray matter volume in mutation carriers (combining *GRN*, *C9orf72*, *MAPT*) versus non-carrier family controls<sup>17,18</sup>. Importantly, a different distribution in genetic groups between our study and the previously conducted studies<sup>17,18</sup> can be noted, with *GRN* being the largest group and *MAPT* being the smallest group in the previous studies while in this study the mutation carriers are enriched for *C9orf72* and *MAPT* carriers, with *GRN* being the smallest group (22% versus 56% in the previous studies). Furthermore, in this study we also included a sporadic FTD cohort without mutations identified in the known FTD genes. Hence, we investigated the association of *TMEM106B* with gray matter volume and cognition in each genetic group separately via interaction modelling and subgroup analyses. We identified associations of *TMEM106B* in the *GRN* and *C9orf72* genetic groups. This is in line with *TMEM106B* being identified as modifier in those with TDP-43 pathology<sup>5,6</sup> but not in most other clinical FTD cohorts of non-TDP<sup>46</sup> or unknown pathology<sup>5,47,48</sup>, with a few exceptions<sup>7,16</sup> potentially due to a substantial proportion of cases with FTLTDP pathology<sup>7,16</sup>. Beyond FTLTDP, *TMEM106B* is associated with hippocampal sclerosis of aging<sup>21,49,50</sup>, with or without accompanying Alzheimer type pathology, with hippocampal sclerosis in

Lewy body disease<sup>51</sup>, and with limbic-predominant age-related TDP-43 proteinopathy (LATE-NC)<sup>52,53</sup>, all characterized by the presence of TDP-43 proteinopathy. Furthermore, TDP-43 inclusions are also present in Alzheimer's disease and Parkinson's disease<sup>54</sup>, explaining the broader modifying roles of *TMEM106B* on endophenotypes such as cognition across neurodegenerative diseases.

Strikingly, *TMEM106B* filaments form aggregates in the brain in elderly and across neurodegenerative diseases<sup>55,56</sup>, with the risk allele associated with greater fibril formation<sup>57</sup> and enhanced TDP-43 dysfunction<sup>58</sup>. While fibril accumulation has been found to be a common age-related phenomenon, fibril aggregates were especially abundant in patients with *GRN* mutations<sup>59</sup>. Both progranulin and *TMEM106B*, are important players in lysosomal health<sup>55</sup>. *TMEM106B* is a transmembrane glycoprotein that primarily localizes to lysosomal membranes where it is proteolytically processed. Progranulin is cleaved in the lysosome into functional granulins, and homozygous loss-of-function mutations in *GRN* cause the lysosomal storage disorder neuronal ceroid lipofuscinosis 11. In addition to convergence of pathomechanisms between *GRN* and *TMEM106B*, *TMEM106B*-induced lysosomal defects due to increased *TMEM106B* expression have been shown to be *C9orf72*-dependent<sup>60</sup>. Altogether, these studies support a specific role for *TMEM106B* as modifier in FTLD-TDP pathophysiology.

We acknowledge that there are limitations with this work. Although we investigated modifying effects of *TMEM106B* in the largest collection of systematically ascertained FTD patients and families from the ALLFTD study, the number of individuals with a *GRN* mutation and two copies of the minor (protective) allele of *TMEM106B*, are small. While this supports a role for *TMEM106B* in reducing disease penetrance, extensive recruitment of unaffected family members of *GRN* mutation carriers followed by genetic analyses of *TMEM106B* and *GRN* will be required to specifically identify those individuals that carry a *GRN* mutation and two copies of the *TMEM106B* minor allele. In addition, to reach the maximum sample size for each outcome measure of interest, the last visit with the measure of interest available was selected. In this way, the analyses differ in their set of unique individuals and their respective time point of assessment, precluding multivariate analysis of variance studies to assess simultaneously associations between *TMEM106B*, imaging and cognition in the same cohort. While we used the largest data set possible, some of our negative statistical associations may be due to small sample sizes. Despite these limitations, we confirmed *TMEM106B* as modifier in *GRN* and *C9orf72* mutation carriers, and reported distinct effects in different genetic groups. Importantly, we showed that *TMEM106B* already exerts effects in the presymptomatic stage of disease. With clinical trials ongoing for gene-based therapies for *GRN* and *C9orf72* mutation carriers, it is important to take *TMEM106B* genetic status into account in the clinical trial design and recruitment of participants.

## STUDY FUNDING AND COMPETING INTERESTS

The ALLFTD consortium is funded by the National Institute on Aging (NIA) and the National Institute of Neurological Diseases and Stroke (NINDS) (U19: AG063911). The former ARTFL and LEFFTDS consortia received funding from the NIA, NINDS and National Center for Advancing Translational Science (U54 NS092089, U01 AG045390). Samples from the National Centralized Repository for Alzheimer Disease and Related Dementias (NCRAD), which receives government support under a cooperative agreement grant (U24 AG021886) awarded by the National Institute on Aging (NIA), were used in this study. M. Vandenberg received funding from the Queen Elisabeth Medical Foundation of Neurosciences (GSKE). E.M. Ramos receives research support from the NIH. N. Corriveau-Lecavalier reports no disclosures relevant to the manuscript. V.K. Ramanan has received research funding from the NIH and the Mangurian Foundation for Lewy Body disease research, has provided educational content for Medscape, has received speaker and conference session honoraria from the American Academy of Neurology Institute, is co-PI for a clinical trial supported by the Alzheimer's Association, is site Co-I for the Alzheimer's Clinical Trials Consortium, and is a site clinician for clinical trials supported by Eisai, the Alzheimer's Treatment and Research Institute at USC, and Transposon Therapeutics, Inc. J. Kornak has provided expert witness testimony for Teva Pharmaceuticals in Forest Laboratories Inc. et al. v. Teva Pharmaceuticals USA, Inc., case numbers 1:14-cv-00121 and 1:14-cv-00686 (D. Del. filed 31 January 2014 and 30 May 2014 regarding the drug Memantine) and for Apotex/HEC/Ezra in Novartis AG et al. v. Apotex Inc., case number 1:15-cv-975 (D. Del. filed 26 October 2015 regarding the drug Fingolimod). He has also given testimony on behalf of Puma Biotechnology in Hsingching Hsu et al, vs. Puma Biotechnology, Inc., et al. 2018 regarding the drug Neratinib. He receives research support from the NIH. C. Mester reports no disclosures relevant to the manuscript. T. Kolander reports no disclosures relevant to the manuscript. D. Brushaber reports no disclosures relevant to the manuscript. A.M. Staffaroni received research support from the NIA/NIH, the Bluefield Project to Cure FTD, the Association for Frontotemporal Dementia, the ALS Association, the Rainwater Charitable Foundation, and the Larry L. Hillblom Foundation. He has provided consultation to Alector, Lilly/Prevail Therapeutics, Passage Bio, and Takeda. He serves on the scientific review board for ADDF. D. Geschwind reports no disclosures relevant to the manuscript. A. Wolf reports no disclosures relevant to the manuscript. K. Kantarci served on the Data Safety Monitoring Board for Takeda Global Research & Development Center and data monitoring boards of Pfizer and Janssen Alzheimer Immunotherapy and received research support from Avid Radiopharmaceuticals, Eli Lilly, the Alzheimer's Drug Discovery Foundation and the NIH. T.F. Gendron receives research support from the NIH. L. Petrucelli receives research support from the NIH. M. Van den Broeck reports no disclosures relevant to the manuscript. S. Wynants reports no disclosures relevant to the manuscript. M.C. Baker reports no disclosures relevant to the

manuscript. S. Borrego-Écija is a recipient of the Joan Rodés Josep Baselga grant from the FBBVA. B. Appleby receives research support from the Centers for Disease Control and Prevention, the National Institutes of Health (NIH), Ionis, Alector and the CJD Foundation. He has provided consultation to Acadia, Ionis and Sangamo. S. Barmada reports no disclosures relevant to the manuscript. A. Bozoki reports no disclosures relevant to the manuscript. D. Clark reports no disclosures relevant to the manuscript. R.R Darby reports no disclosures relevant to the manuscript. B.C. Dickerson is a consultant for Acadia, Alector, Arkuda, Biogen, Denali, Eisai, Genentech, Lilly, Merck, Novartis, Takeda and Wave Lifesciences, receives royalties from Cambridge University Press, Elsevier and Oxford University Press, and receives grant funding from the NIA, the National Institute of Neurological Disorders and Stroke, the National Institute of Mental Health and the Bluefield Foundation. K. Domoto-Reilly receives research support from the NIH and serves as an investigator for a clinical trial sponsored by Lawson Health Research Institute. J.A. Fields receives research support from the NIH. D. R. Galasko reports no disclosures relevant to the manuscript. N.Ghoshal has participated or is currently participating in clinical trials of anti-dementia drugs sponsored by Bristol Myers Squibb, Eli Lilly/Avid Radiopharmaceuticals, Janssen Immunotherapy, Novartis, Pfizer, Wyeth, SNIFF (The Study of Nasal Insulin to Fight Forgetfulness) and the A4 (The Anti-Amyloid Treatment in Asymptomatic Alzheimer's Disease) trial. She receives research support from Tau Consortium and the Association for Frontotemporal Dementia and is funded by the NIH. N. Graff-Radford receives royalties from UpToDate and has participated in multicenter therapy studies by sponsored by Biogen, TauRx, and Lilly. He receives research support from the NIH. I.M. Grant reports no disclosures relevant to the manuscript. L.S. Honig receives research funding from Abbvie, Acumen, Alector, Biogen, BMS, Eisai, Genentech/Roche, Janssen/J&J, Transposon, UCB, Vaccinex, and consulting fees from Biogen, Cortexyme, Eisai, Medscape, Prevail/Lilly. G-Y R Hsiung has served as an investigator for clinical trials sponsored by AstraZeneca, Eli Lilly and Roche/Genentech. He receives research support from the Canadian Institutes of Health Research and the Alzheimer Society of British Columbia. E.D. Huey receives research support from the NIH. D. Irwin receives support from the NIH, BrightFocus Foundation and Penn Institute on Aging. D.S. Knopman serves on the data and safety monitoring board of the DIAN-TU study; is a site principal investigator for clinical trials sponsored by Biogen, Lilly and the University of Southern California; and is funded by the NIH. J. Kwan reports no disclosures relevant to the manuscript. G.C. Léger reports no disclosures relevant to the manuscript. I. Litvan is supported by the National Institutes of Health grants: 2R01AG038791-06A, U01NS100610, U01NS80818, R25NS098999; U19 AG063911-1 and 1R21NS114764-01A1; the Michael J Fox Foundation, Parkinson Foundation, Lewy Body Association, CurePSP, Roche, Abbvie, Biogen, Centogene. EIP-Pharma, Biohaven Pharmaceuticals, Novartis, Brain Neurotherapy Bio and United Biopharma SRL - UCB. She is a Scientific advisor for Amydis and Rossy Center for Progressive Supranuclear Palsy University of Toronto . She receives her salary from the University of

California San Diego and as Chief Editor of *Frontiers in Neurology*. J.S. Masdeu reports no disclosures relevant to the manuscript. M.F. Mendez receives research support from the NIH. C.U. Onyike receives research funding from the NIH, Lawton Health Research Institute, National Ataxia Foundation, Alector and Transposon. He is also supported by the Robert and Nancy Hall Brain Research Fund, the Jane Tanger Black Fund for Young-Onset Dementias and a gift from Joseph Trovato. He is a consultant with Alector Inc., Acadia Pharmaceuticals, and Reata Pharmaceuticals. B. Pascual reports no disclosures relevant to the manuscript. P. Pressman reports no disclosures relevant to the manuscript. A. Ritter reports no disclosures relevant to the manuscript. E.D. Roberson has received research support from the NIH, the Bluefield Project to Cure Frontotemporal Dementia, the Alzheimer's Association, the Alzheimer's Drug Discovery Foundation, the BrightFocus Foundation, and Alector; has served as a consultant for AGTC and on a data monitoring committee for Lilly; and owns intellectual property related to tau and progranulin. A. Snyder reports no disclosures relevant to the manuscript. A Campbell Sullivan reports no disclosures relevant to the manuscript. M.C. Tartaglia has served as an investigator for clinical trials sponsored by Biogen, Avanex, Green Valley, Roche/Genentech, Bristol Myers Squibb, Eli Lilly/Avid Radiopharmaceuticals and Janssen. She receives research support from the Canadian Institutes of Health Research. D. Wint reports no disclosures relevant to the manuscript. H.W. Heuer reports no disclosures relevant to the manuscript. L.K. Forsberg reports no disclosures relevant to the manuscript. A.L. Boxer receives research support from the NIH, the Tau Research Consortium, the Association for Frontotemporal Degeneration, Bluefield Project to Cure Frontotemporal Dementia, Corticobasal Degeneration Solutions, the Alzheimer's Drug Discovery Foundation and the Alzheimer's Association. He has served as a consultant for Aeovian, AGTC, Alector, Arkuda, Arvinas, Boehringer Ingelheim, Denali, GSK, Life Edit, Humana, Oligomerix, Oscotec, Roche, TrueBinding, Wave, Merck and received research support from Biogen, Eisai and Regeneron. H.J. Rosen has received research support from Biogen Pharmaceuticals, has consulting agreements with Wave Neuroscience, Ionis Pharmaceuticals, Eisai Pharmaceuticals, and Genentech, and receives research support from the NIH and the state of California. B.F. Boeve has served as an investigator for clinical trials sponsored by Alector, Biogen, Transposon and Cognition Therapeutics. He serves on the Scientific Advisory Board of the Tau Consortium which is funded by the Rainwater Charitable Foundation. He receives research support from NIH. R.R. receives research funding from the NIH and the Bluefield Project to Cure Frontotemporal Dementia. R.R. is on the scientific advisory board of Arkuda Therapeutics and receives royalties from progranulin-related patent. She is also on the scientific advisory board of the Foundation Alzheimer.

## **ACKNOWLEDGEMENTS**

We wish to express our gratitude towards all ALLFTD participants and their caregivers for the dedicated participation in this research program. We also thank all personnel involved in the ALLFTD consortium who are not listed as co-authors.
