Schift is a contributing significantly to the worldwide burden of disease<sup>1</sup>. Over the past decade,<br>E-wide association studies (GWAS) have identified many genomic loci associated with<br>hrenia, revealing its heterogeneous a population, contributing significantly to the worldwide burden of disease<sup>4</sup>. Over the past decade,<br>genome-wide association studies (GWAS) have identified many genomic loci associated with<br>schizophrenia, revealing its hete schizophrenia, revealing its heterogeneous and multifaceted nature<sup>2–6</sup>. However, gleaning bio<br>insights from GWAS results has proven challenging, with downstream analyses pointing broad<br>neuronal and synaptic mechanisms wit schizophrenia, revealing its heterogeneous and multifaceted nature<sup>2</sup> °. However, gleaning biological<br>insights from GWAS results has proven challenging, with downstream analyses pointing broadly towa<br>neuronal and synaptic insights from CMM CMM MATCH MATHONG, MIN ACTIVE CHALLENDING (POMAG) CONDITED AND previously considered and synaptic mechanisms without clear mechanistic differentiation<sup>2,4,7</sup>. Pleiotropic analyses, combining GWAS of schiz neuronal and synaptic mechanisms without clear mechanistic differentiation<sup>2,4,7</sup>'. Pleiotropic analyses,<br>combining GWAS of schizophrenia with other genetically correlated forms of psychopathology, have<br>boosted the power o boosted the power of gene set enrichment analyses; such studies have implicated a range of<br>neurodevelopmental, synaptic, and other molecular pathways<sup>8,9</sup> but have not adequately parsed the<br>association of individual pathwa boosted the power of gene set enrichment analyses; such statics have not adequately par<br>heurodevelopmental, synaptic, and other molecular pathways<sup>8,9</sup> but have not adequately par<br>association of individual pathways with sp

neurodevelopmental, synaptic, and other molecular pathways<sup>9,9</sup> but have not adequately parsed the<br>association of individual pathways with specific phenotypic features.<br>In two recent studies<sup>10,11</sup>, we have demonstrated th associated that pleiotron in two recent studies<sup>10,11</sup>, we have demonstrated that pleiotron and the specific phenotypic features.<br>Associated with specific phenotypic features.<br>Associated with specific phenotypic features. In two recent studies<sup>20,11</sup>, we have demonstrated that pleiotropic analysis of schizophrenia<br>with cognitive endophenotypes may permit well-powered, fine-grained, mechanistic<br>tiation of molecular pathways associated with s differentiation of molecular pathways associated with specific phenotypic constellations. Im<br>cognitive ability is a core dimension of schizophrenia pathology<sup>12</sup>; cognitive deficits often en<br>frequently preceding schizophre cognitive ability is a core dimension of schizophrenia pathology<sup>12</sup>; cognitive deficits often emerge e<br>frequently preceding schizophrenia's onset by years and contributing to diminished functional<br>outcomes, including educ cognitive ability is a core dimension of schizophrenia pathology\*\*; cognitive deficits often emerge early,<br>frequently preceding schizophrenia's onset by years and contributing to diminished functional<br>outcomes, including e frequently preceding schizophrenia's onset by years and contributing to diminished functional<br>outcomes, including educational attainment<sup>13</sup>. Moreover, recent GWAS of cognition and educa<br>attainment demonstrate significant outcomes, including educational attainment<sup>13</sup>. Moreover, recent GWAS of cognition and educational<br>attainment demonstrate significant overlap with schizophrenia risk loci<sup>10,14–17</sup>. However, genetic<br>correlation analyses re attainment demonstrate significant overlap with schizophrenia risk loci<sup>+0,14–1</sup>'. However, genetic<br>correlation analyses reveal a nuanced relationship between cognitive function, educational attail<br>and schizophrenia risk. and schizophrenia risk. While there is a significant negative genetic correlation between reduced<br>cognitive function and increased schizophrenia susceptibility ( $r_g \approx -0.20$ ), there exists a paradoxical,<br>positive genetic c cognitive function and increased schizophrenia susceptibility (r<sub>g</sub>  $\approx$  –0.20), there exists a paradoxic<br>positive genetic correlation between greater educational attainment and schizophrenia risk (r<sub>g</sub>  $\approx$  0<br>despite a s positive genetic correlation between greater educational attainment and schizophrenia risk (r<sub>g</sub> ≈ 0.1<br>despite a strong genetic overlap between educational attainment and cognitive ability (r<sub>g</sub> ≈ 0.70). positive generic correlation between educational attainment and cognitive ability ( $r_g \approx 0.70$ ), despite a strong genetic overlap between educational attainment and cognitive ability ( $r_g \approx 0.70$ ), despite a strong genetic overlap between educational attainment and cognitive ability (rg ≈ 0.70).

Thus, while the two can be exploited in pleiotropic analyses of<br>threnia. In our previous work<sup>10,11</sup>, we identified two distinct subsets of schizophrenia-re<br>loci: those with "concordant" alleles that align with expectatio schizophrenia. In our previous work $^{10,11}$ , we identified two distinct subsets of schizophrenia-<br>genetic loci: those with "concordant" alleles that align with expectations—lower cognition/e<br>and increased illness risk—an genetic loci: those with "concordant" alleles that align with expectations-lower cognition/education and increased illness risk—and "discordant" SNPs that show higher educational attainment and/or<br>cognitive ability alongside greater schizophrenia susceptibility. This distinction is obscured when<br>pleiotropy is examined gl cognitive ability alongside greater schizophrenia susceptibility. This distinction is obscured when<br>pleiotropy is examined globally, using only genomewide correlational analysis ( $r_g$ ). Downstream<br>analyses of concordant l pleiotropy is examined globally, using only genomewide correlational analysis (r<sub>g</sub>). Downstream<br>analyses of concordant loci implicated neurodevelopmental pathways in schizophrenia, while<br>discordant loci were associated wi pleases of concordant loci implicated neurodevelopmental pathways in schizophrenia, while<br>discordant loci were associated with postnatally expressed synaptic mechanisms underlying the<br>disorder. discordant loci were associated with postnatally expressed synaptic mechanisms underlying the<br>discordant loci were associated with postnatally expressed synaptic mechanisms underlying the<br>disorder. disorder.<br>The present study was designed to replicate and extend our prior pleiotropic meta-analysis,

utilizing substantially larger input GWAS for schizophrenia, cognitive task performance, and  $\begin{array}{c} \n\frac{1}{2} & \frac{1}{2} \\ \n\frac{1}{2} & \frac{1}{$ The present study and the present study is understood to replice the present study is understanding to replicate and total attainment than were available in our prior report<sup>10</sup>. Moreover, in the current varion, we applied utilizing substantially larger input GWAS for statistic margins larger interpretational attainment than were available in our prior report<sup>10</sup>. Moreover, in the current investigation, we applied a novel, more powerful meta educational attainment than were available in our prior report<sup>20</sup>. Moreover, in the current<br>investigation, we applied a novel, more powerful meta-analytic approach to pleiotropy, the<br>Locus Exploration and Interpretation u Increases Exploration, and Interpretation using Optimal test' (PLEIO)<sup>18</sup>. This methodology permits a direct assessment of the directional associations among these phenotypes. Based on our prior report, we anticipate the i Locus Exploration and Interpretation using Optimal test' (PLEIO)<sup>20</sup>. This methodology permits a direct<br>assessment of the directional associations among these phenotypes. Based on our prior report, we<br>anticipate the identi anticipate the identification of novel loci previously unreported in discovery GWAS datasets.<br>Additionally, post-GWAS annotation of these pleiotropically identified loci is expected to extend<br>beyond neurodevelopmental and Additionally, post-GWAS annotation of these pleiotropically identified loci is expected to exte<br>beyond neurodevelopmental and synaptic pathways, offering deeper insights into the biologi<br>mechanisms underpinning these assoc beyond neurodevelopmental and synaptic pathways, offering deeper insights into the biological<br>mechanisms underpinning these associations (Figure 1). beyond the sympath and sympathy  $\frac{1}{2}$  of  $\frac{1}{2}$  of  $\frac{1}{2}$  of the biological mechanisms underpinning these associations (Figure 1). mechanisms underpinning these associations (Figure 1).

that adequately support study objectives: ASSET (Association analysis based on subsets)<sup>22</sup> and PLEIO<br>(Pleiotropic Locus Exploration and Interpretation using Optimal test)<sup>18</sup>. PLEIO overcomes limitations<br>associated with f (Pleiotropic Locus Exploration and Interpretation using Optimal test)<sup>19</sup>. PLEIO overcomes limitations<br>associated with fixed-effect model approaches by employing a random-effect model to capture gene<br>correlations and herit correlations and heritabilities across trait pairs<sup>18</sup>. Relative to ASSET, PLEIO is more computationally<br>efficient and provides greater power in simulations across a range of different heritabilities<sup>18</sup>. Linkage<br>disequili efficient and provides greater power in simulations across a range of different heritabilities<sup>18</sup>. Linkage<br>disequilibrium score regression (LDSC) implemented within PLEIO estimates genetic covariance and<br>environmental cor disequilibrium score regression (LDSC) implemented within PLEIO estimates genetic covariance and

Consistent with our earlier study, we reversed the effect direction per variant for schizophrenia Consistent with our earlier study, we reversed the effect direction per variant for s<br>to align with the interpretation of allelic effects on cognition and education<sup>10</sup>; in other wo  $\frac{1}{2}$ with the interpretation of allelic effects on cognition and education<sup>10</sup>; in other words,<br>sed risk for schizophrenia was coded by positive allelic effects, just as higher scores on cognitive<br>rformance and educational atta to align with the interpretation of allelic effects on cognition and education<sup>10</sup>; in other words,<br>decreased risk for schizophrenia was coded by positive allelic effects, just as higher scores on (<br>task performance and ed decreased risk for schizophrenia was consider and ansied therein, yield as in our school can take the explanation<br>task performance and educational attainment are coded with positive allelic effects. By applying PLEIO,<br>we i the state of variants, concordant and discordant, defined as in our prior study<sup>8</sup>. In the<br>notation that follows, the symbol **a** indicates variant subsets with the same effect direction across the<br>traits, and the symbol | we identified two subsets of variants, concordant and discordant, defined as in our prior study<sup>o</sup>. In the notation that follows, the symbol **a** indicates variant subsets with the same effect direction across the traits, a notation that follows, the symbol  $|$  represents traits whose effect sizes exhibit the opposite direction compared to<br>the other two traits. Thus, the concordant subset includes variants with the same effect direction (i.e. the other two traits. Thus, the concordant subset includes variants with the same effect direction (i.e.,<br>scz  $\mathbb B$  edu  $\mathbb B$  cog, after reversal of sign for schizophrenia). By contrast, the discordant subset includes<br>th  $\texttt{ncz} \boxtimes \texttt{d}$  edu  $\boxtimes \texttt{cog}$ , after reversal of sign for schizophrenia). By contrast, the discordant subset includes three distinct sets of variants: (i) edu  $\boxtimes \texttt{cog} \mid \texttt{scz}$  (schizophrenia outliers, i.e., sam script of three distinct sets of variants: (i) edu  $\mathbb{Z}$  cog | scz (schizophrenia outliers, i.e., same allele is associated<br>with an increase in cognitive ability, educational attainment, and schizophrenia risk); (ii) sc with an increase in cognitive ability, educational attainment, and schizophrenia risk); (ii) scz **Z cog | edu**<br>(education outliers, i.e., variants associated with an increase in schizophrenia risk and reduced (education outliers, i.e., variants associated with an increase in schizophrenia risk and reduced<br>cognitive ability, but increased educational attainment); and (iii) scz  $\mathbb{D}$  edu | cog (cognition outliers, i.e.,<br>varia (educational attainment); and (iii) scz  $\mathbb{D}$  edu | cog (cognition outlog cognition) outlog variants associated with an increase in schizophrenia risk and reduced educational attainment in an increase in schizophrenia variants associated with an increase in schizophrenia risk and reduced educational attainment but<br>6 variants associated with an increase in schizophrenia risk and reduced educational attainment but

increased cognitive ability). Independent genome-wide significant loci (p<5x10<sup>-8</sup>) were identified using<br>the Functional Mapping and Annotation (FUMA) pipeline<sup>23</sup> (See Data Availability). We excluded the<br>MHC region (chr6 MHC region (chr6:25000000-3500000) from further analysis due to its complex LD patterns, opting to

After harmonization in FUMA (see supplementary methods), we identified three distinct sets of genome-wide significant loci (Figure 2): (i) 347 independent loci with exclusively concordant genome- $\frac{1}{2}$ wide significant loci were discordant (Supplementary Table 2); and (iii) 151 "dual" loci, containing both wide significant SNPs (Supplementary Table 1); (ii) 270 independent genomic loci in which all genome-<br>wide significant loci were discordant (Supplementary Table 2); and (iii) 151 "dual" loci, containing both<br>concordant and variant set is novel, ostensibly due to the increased power of the larger input GWAS sample sizes. Next, concordant and discordant variants (Supplementary Methods; <u>Supplementary Table 3</u>). The 'dual'<br>variant set is novel, ostensibly due to the increased power of the larger input GWAS sample sizes. Next,<br>we compared these res conciant set is novel, ostensibly due to the increased power of the larger input GWAS sample sizes.<br>We compared these results with our prior report<sup>8</sup>, where we reported only Concordant (89 loci) an<br>Discordant (65 loci) wi variant set in they settled, and to the increased power of the included power of the larger input GWAS and<br>we compared these results with our prior report<sup>8</sup>, where we reported only Concordant (89 loci) and<br>Discordant (65 Discordant (65 loci) with earlier and more modestly sampled versions of the input GWAS.

To identify novel loci emerging from our PLEIO meta-analysis, we merged the loci reported for schizophrenia, cognitive task performance, and educational attainment in the original input GWAS To identical attainment in the original input GWAS<br>Tons, along with loci obtained from our pleiotropic meta-analysis using the "merge" option in<br>Is<sup>224</sup>. (We first employed FUMA to map significant variants to loci for educ schizophrenia, cognitive task performance, and educational attainment in the original input Control<br>publications, along with loci obtained from our pleiotropic meta-analysis using the "merge" option<br>"bedtools"<sup>24</sup>. (We fir publications, along with locations, along the "merget" of the "merget" of the "meta-analysis" of "meta-analysis" of "meta-analysis" of "meta-analysis" of "meta-analysis" option ince the "merginal publication lacked compar 'bedtools'<sup>24</sup>. (We first employed FUMA to map significant variants to loci for education since the<br>original publication lacked comparable locus information.) This process yielded 739 genome-wide<br>significant (p < 5x10<sup>-8</sup>) significant  $(p < 5x10^{-8})$  loci emerging from the pleiotropic meta-analysis, as well as 280 loci for<br>schizophrenia, 432 for education, and 292 for cognitive task performance; these numbers differ sli<br>from the original repor schizophrenia, 432 for education, and 292 for cognitive task performance; these numbers differ slightly<br>from the original reports due to the merging of partially overlapping loci in bedtools (see schizophrenia, 423 for education, and 292 for cognitive task performance; these numbers different slightly<br>from the original reports due to the merging of partially overlapping loci in bedtools (see<br>7 from the original reports due to the merging of partially overlapping loci in bedtools (see

Supplementary Methods). A Venn diagram of these results is presented in Figure 3, revealing that 166<br>PLEIO loci are not being identified in any of the three input GWASs. By contrast, several loci remained<br>specific to the i specific to the input GWASs and did not reach genome-wide significance in the pleiotropic meta-<br>analysis (schizophrenia: 94; education: 46; cognitive task performance: 52), presumably indicating that<br>these loci were specif these loci were specific to one phenotype and not pleiotropic.<br>Comparing results with our earlier pleiotropic meta-analytic study<sup>8</sup>, we identified 110 novel

these loci were specific to one phenotype and not pleistic to phenote<br>Comparing results with our earlier pleiotropic meta-and<br>loci.
