27 **Abstract**

28 **Background:** With a disproportionate burden of chronic diseases and severe shortage of health
29 workers in sub-Saharan Africa (SSA), the region implicitly relies on informal caregivers (ICGs)
30 to support the patients both within and outside the health facilities. The aim of this review is to
31 explore the health and economic impact of caregiving on ICGs of patients with chronic diseases
32 in SSA.

33 **Methods:** Medline (Ovid), CINAHL (EBSCOhost), PsycINFO (Ovid), Embase (Ovid), Global
34 Health and Web of Science databases were systematically searched to identify original articles
35 that considered the economic and/or health impacts of caregiving in SSA. The results from the
36 included studies were synthesised narratively.

37 **Results:** After screening 4,372 articles, 47 were included for synthesis. The articles were from
38 all sub-regions of SSA with more than half (25/47) of the articles focussing on caregivers for
39 patients with cancer. Although the primary motivation for becoming caregivers was love and
40 responsibility, the caring responsibilities described in twenty articles, had profound effects on
41 the caregiver's lives. Healthwise, ICGs experienced changes in their physical and mental health
42 like developing musculoskeletal problems and depression. Economically, caregiving was
43 expensive, and financially draining. The opportunity cost of caregiving included loss of jobs,
44 loss of income, foregoing planned important activities and missed education opportunities.

45 **Conclusion:** ICGs reported a range of mainly negative health and economic effects of the work
46 they do. Health care systems should consider how to better support ICGs in terms of their own
47 physical and mental wellbeing and governments should consider how to better financially
48 support ICGs.

49 **Key Words:**

50 Informal caregivers, sub-Saharan Africa, chronic diseases

52 **Introduction**

53 Global increases in healthcare expenditure have not been proportional across the world (1). In
54 sub-Saharan Africa (SSA), government spending on health is very low whilst out-of-pocket
55 expenditure is significantly high. These countries do not have well-developed health insurance
56 system and the out-of-pocket health expenditure is sometimes higher than 70% (2,3). Universal
57 health insurance is still in its infancy in SSA, with only four countries having coverage levels
58 above 20% (3,4). Therefore, the family (informal caregiver) of a person with a chronic disease
59 in this region is often faced with a double burden of because of the long-term nature of the disease
60 and the limited availability of diagnostic and disease management services (5). Chronic diseases
61 which are projected to be the leading cause of morbidity and mortality in Africa by 2030 are
62 slow-progressing diseases that last long in the body and cannot be transmitted from one person
63 to another (6,7).

64 The term informal caregiver (ICG) is used to refer to any layperson who provides regular
65 emotional, physical, financial, and medical support to the sick or to people with disabilities, often
66 without expectation of an immediate reward (8,9). Throughout this review, ‘ICG’ and ‘caregiver’
67 are used interchangeably to mean the same thing unless otherwise specified. Many times, ICGs
68 have a familial relationship with the care recipient, often assuming the caregiving role as parents,
69 spouses, children, siblings, or other relatives. These caregivers are predominantly female and
70 frequently take on the caregiving role with minimal or no preparation (10). It is understood that
71 the ICGs in SSA perform numerous tasks, some of which are typically responsibilities of
72 healthcare professionals in other parts of the world (10,11). They perform these activities
73 whenever required, whether day or night, at home or in the hospital and under any situation. For
74 example, ICGs sometimes sleep on hospital floors during the night to provide companionship
75 and maintain close proximity to the care recipient in order to address any immediate concerns
76 required by either the patient or the medical personnel at the hospital (12). Accordingly, they are
77 faced with unique challenges, such as overwhelming responsibilities, high out-of-pocket health
78 expenditure, stigma, and limited access to healthcare services (10,11).

79 Over the years, reviews have been conducted to assess the impact of caregiving in SSA. The
80 focus of these reviews has been on specific conditions such as HIV (13), cancers (10), old age,
81 end-of-life care (14), mental health disorders (15) and stroke. Other researchers limited their
82 reviews to studies within specific countries (16) or specific settings like hospitals (17).

83 In this review, we aimed to systematically summarise evidence on the health and economic
84 impact of caregiving on ICGs of patients with chronic diseases in the whole of SSA. This was
85 achieved through the following three objectives: 1) To describe the activities ICGs of people
86 with chronic diseases in SSA perform 2) To discuss the reasons why ICGs of people with chronic
87 diseases in SSA took on the caregiving roles 3) To explore the health and economic impact of
88 caregiving on ICGs of people with chronic diseases in SSA. From our understanding, this is the
89 first review to explore how caregiving affects the health and economic aspects of caregivers of
90 people with major chronic diseases in the whole of SSA.

91 **Methods**

92 This systematic review was conducted, adhering to the guidelines laid out in the Preferred
93 Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement (18). The
94 protocol for this review was registered with PROSPERO under the registration number of
95 CRD42022358531. The databases were searched between September and October 2022.

96 **Eligibility criteria**

97 The criteria for selecting studies were as follows:

98 **Study design:** All original studies, irrespective of the design were included in this review.
99 These included randomised controlled trials, case-control, cohort, cross-sectional and qualitative
100 studies. However, commentaries and reviews were excluded.

101 **Population:** Studies with ICGs providing care to people with chronic diseases were included.
102 We included the most common chronic diseases which are known to cause significant morbidity
103 and over 80% of premature deaths - these were cardiovascular diseases, chronic obstructive
104 pulmonary diseases, cancers and Type 2 diabetes (19). We excluded mental health conditions
105 and those with a co-morbidity that is not a chronic disease of interest. We did not include studies
106 that had less than half (50%) of ICGs in active caregiving roles. Caregivers may not actively
107 provide care when the care recipient has significantly improved, died and when another person
108 has taken over the caring role. We also excluded studies where results for the population of
109 interest were pooled with others (such as professional caregivers, paid caregivers, and
110 volunteers) and if the proportion of the population of interest was under 50%. Such studies would
111 dilute the relevance of the findings and make them less applicable to ICGs, who are this review's

112 population of interest. Where results were presented separately for the population of interest, we
113 included the studies regardless of what proportion of the total sample they made up.

114 **Outcomes:** The studies that were selected for inclusion in this review had findings with
115 information about how caregiving affected the health or economic aspects of the ICG's life. Such
116 information had to be provided in the findings.

117 **Setting:** Studies were selected if they were conducted within SSA as defined by World Bank
118 (<https://openknowledge.worldbank.org/pages/focus-sub-saharan-africa>). The search was not
119 restricted to any language since articles published in languages other than English were
120 translated.

121 **Information sources**

122 EK searched for relevant original articles from the following databases between September and
123 October 2022: Medline (Ovid), CINAHL (EBSCOhost), PsycINFO (Ovid), Embase (Ovid),
124 Global Health and Web of Science. The searches were conducted from the inception of each
125 database up to the date of each search. Full details of the searches including the databases, search
126 strategy and the search outcomes can be found in **S1 File**.

127 In addition, the reference lists of selected articles and relevant systematic review reports were
128 searched. Lastly, primary authors of editorial letters, abstracts from conference proceedings,
129 abstracts without full-text articles and commentaries identified through the searches were
130 contacted by email for full-text original articles.

131 **Search strategy**

132 The search strategy development process involved identifying candidate search terms by reading
133 the titles, abstracts, keywords, and search strategies in the three known related articles (17,20,21).
134 A draft search string was formed by appropriately combining the identified search terms and
135 MeSH terms using Boolean operators. The search terms: Informal caregiver, sub-Saharan Africa,
136 and Chronic Diseases, were combined using the Boolean operator "AND," while the thesauruses
137 and MeSH words for each search term were combined using "OR." This was improved after a
138 review and discussion with two senior researchers (BB and MH) and a librarian from King's
139 College London, all of whom have experience in systematic reviews. This was purposely done
140 to reduce the errors and increase the robustness of the search strategy. The final search string as
141 used in each database can be found in **S1 File**.

142 **Selection process**

143 The articles that were retrieved from all the searched databases were exported to Endnote
144 (version 20) for removal of the duplicate articles. This was done by the first reviewer (EK). The
145 remaining articles were then transferred to Rayyan software (<https://www.rayyan.ai/>) where title
146 and abstract screening was done. The articles that did not meet the agreed criteria were excluded
147 while those that potentially met the eligibility criteria were included for full-text screening. Full-
148 text screening was carried out for the articles whose full-text versions were retrieved. The articles
149 whose full-texts were unavailable even after contacting the primary authors were excluded. At
150 each stage, the screening was independently conducted by two reviewers. While EK screened all
151 the articles in both stages, the second reviewer (ELM) screened a random 20% of the articles at
152 the title and abstract screening stage, and a random 25% during the full-text screening. There
153 was 96% agreement between the two reviewers and all disagreements were resolved by a
154 discussion with input from other authors. In this review, all non-English papers were translated
155 into English using Google Translate, a choice made due to its known reliability and accuracy in
156 English with 91% agreement between native language reviewers and reviews who use google
157 translate (range, 85% to 97%) (22).

158 **Quality of the included studies**

159 The quality of the articles was independently assessed by two reviewers (EK and ELM) using
160 the Mixed Methods Appraisal Tool, a critical appraisal tool that has been tested and found to be
161 reliable and efficient (23,24). It is used to assess the quality of studies of different designs
162 including qualitative and quantitative studies. For each article (depending on the study design),
163 there are five (5) questions that require a response of Yes, No or Can't Tell. In this review, the
164 Yes was given a score of 1 and No or Can't Tell was given a score of 0. Any disagreement was
165 resolved by consensus.

166 **Data extraction and analysis**

167 Relevant data was extracted from all articles by EK and entered into a data extraction form,
168 developed with the study objectives in mind. The data that was extracted into the form included;
169 the name of the first author of the study, the year of publication, the country where the study was
170 conducted, study design, sample size, participants' age and sex, their marital and employment
171 status, the relationship of ICG to the patient, activities done by the ICG, setting (home or hospital
172 setting), type of chronic disease, scale used to measure impact, the health and economic impact

173 of caregiving on ICG and the ICGs' motivation to provide care. Thereafter, data were synthesized
174 narratively.

175

176 **Results**

177 **Study selection**

178 As shown in the PRISMA diagram in Fig 1, 4372 records were retrieved through a systematic
179 search of seven databases (4368) and a targeted search of the reference list of the already
180 identified relevant articles (4). After removing 2005 duplicate articles, 2194 articles were
181 excluded during the title and abstract screening and another 27 articles were also excluded
182 because they were conference abstracts whose full-text articles could not be retrieved. During
183 the full-text screening, 99 articles were excluded for various reasons and only 45 studies (with
184 47 articles) were included in the review.

185 **Fig 1. PRISMA flow diagram of the screening and selection process in this review**

186 **Study characteristics**

187 All articles were written in English except one that was in French (25). The authors used
188 qualitative and quantitative methods in 22 and 24 of the 47 articles respectively, with one article
189 using mixed methods. Of the quantitative studies, three (26–28) were longitudinal studies and
190 the rest had a cross-sectional study design. The articles were from fourteen countries representing
191 all the sub-regions of SSA. The highest number of articles (11/47) were from Nigeria (29–39)
192 and South Africa (11,26,27,40–47), while each of the following countries had one (1/47) article;
193 Togo (48), Zimbabwe (49), Kenya (50), Sudan (51), Democratic Republic of Congo (52) and
194 Cameroon (25). Among the articles from South Africa, two used data from the same study
195 (42,43). Also, data from a single study in Ghana was used in two of the five articles (53,54). See

196 **Table 1**

197

198

199

201 **Table 1. Summary of the characteristics of the reviewed articles**

Author, year	Country	Setting	Participants	Sample size	Disease	Relationship to Patient	Duration of caring	Time spent in care
Yusuf (2011) (29)	Nigeria	Outpatients	Family caregivers Mean age: 57 years Age range: Not reported Sex: Female, 43 (42%) Employment: Unemployed 25 (24.3%) Employed 78 (75.7%)	103	Cancers (Not specified)	Spouse: 3 (2.9%) Son/daughter: 74 (71.9%) Sibling: 26 (25.2%)	Not reported	Not reported
Wassie (2022) (56)	Ethiopia	Admitted in hospital	ICGs of adults Mean age: 35 years Age range: Not reported Sex: Female, 176 (42.72%) Employment: Employed 282 (68.44%)/Unemployed 130 (31.56%)	412	Breast cancer 91 (22.09%); Cervical cancer 54(13.11%); Gastric cancer 30(7.28%); Others 237 (57.52%)	Spouse 140 (33.98%); Child 150 (36.41%); Siblings 85 (20.63%); Parents 21 (5.1%); Other relatives 16 (3.88%);	more than 2 weeks	Not reported
Walubita (2018) (12)	Zambia	Admitted in hospital	ICGs of children with cancers Mean age: Not reported Age range: 20 to 58 years Sex: Female, 14 (93.3%) Employment: Not reported	15	Cancer of the kidney (4), Leukaemia (3), Retinol blastoma (3), Lymphoma (2), Cancer of the liver (1), Cancer of the lungs (1)	Parent 12; Grandparent 2; Great grandparent 1;	Not reported	Not reported
Vincent-Onabajo (2018) (30)	Nigeria	Not institutionalised	ICGs of people with stroke Mean age: 33.2 years Age range: 19 to 60 years Sex: Female, 55 (61.1%) Employment: Unemployed 60 (66.7%)/Employed 30 (33.3%)	90	Stroke	Offspring 53 (58.9%); Spouse 22 (24.4%); Sibling 15 (16.7%).	Not reported	Not reported
Thomas (2008) (40)	South Africa	Not institutionalised	Primary ICGs Mean age: 47.2 years Age range: 16 to 67 years Sex: Female, Female 4 (66.7) Employment: Not reported	6	Stroke	Husbands 2 (33.3); Wife 2 (33.3%); Daughters 2 (33.3%)	Not reported	Always with the care recipient
Tchokote (2020) (25)	Cameroon	Not institutionalised	Primary or secondary ICGs Mean age: 32.75 years Age range: 20 to 50 years Sex: Female, Female 2 (50%) Employment: Employed 1 (25%); Unemployed 3 (75%)	4	Stroke	Grandchildren 2 (50%); Wife 1 (25%); Daughter 1 (25%)	Not reported	Not reported
Serfontein (2019) (26)	South Africa	Admitted in a Rehabilitation centre	Primary ICGs Mean age: Not reported Age range: 23 to 76 years Sex: Female, Female 50 (79.4%) Employment: Employed 30 (47.6%); Unemployed 33 (52.4%)	63	Cerebrovascular accident (CVA)	Spouses 32 (50.8%); Children 18 (28.6%); Other relatives (13 20.6%)	≥ 2 months	13.2% (5) spend ≥4 hours/day 55.6% (35) spend 2-4 hours/day & 23.8% (15) spent 5-6 hours/day
Scheffler (2019) (27)	South Africa	Not institutionalised	ICGs [73/80 (91.2%)-ICGs; & 7/80 (8.8%) paid carers] Mean age: 47.4 years,	89	Stroke	Spouse/partner 25 (28.4%) Son/daughter 33 (37.5%)	Not reported	Not reported

			Age range: 12 to 79 years Sex: Female, Female 73 (82.0%) Employment: Not reported			Other family 19 (21.6%) Friend 6 (6.8%) Other 6 (5.7%)		
Owoo (2022) (54)	Ghana	Not clear	Family caregivers Mean age: 48.67 years Age range: 27 to 67 years Sex: Female, Female 11 (91.67%) Employment: Employed: 9 (75%); Unemployed: 3 (25%)	12	Prostate cancer	Father 6 (50%) Husband 6 (50%)	1 year 8 (66.67%) 2 years 3 (25%) 6 months 1 (8.33%)	Not reported
Owoo (2022) (53)	Ghana	Not reported	Family caregivers Mean age: 48.67 years Age range: 27 to 67 years Sex: Female, Female 11 (91.67%) Employment: Employed: 9 (75%); Unemployed: 3 (25%)	12	Prostate cancer	Father 6 (50%) Husband 6 (50%)	1 year 8 (66.67%) 2 years 3 (25%) 6 months 1 (8.33%)	Not reported
Onyeneho (2021) (31)	Nigeria	Not reported	Primary caregiver Mean age: 37.68 YEARS Age range: 10 to >51 years Sex: Female, Female 11 (91.67%) Employment: Employed: 9 (75%); Unemployed: 3 (25%)	182	Cancer (Not specified)	Brother 12 (6.6%) Sister 20 (11.0%) Parents 119 (65.4%) Husband 17 (9.3%) Wife 14 (7.7%)	<1 month 52 (28.6%) 1 month to 6 months 63 (34.6%) >6 months to 1 year 21 (11.5%) >1 year 46 (25.3%) Mean±SD 2.34±1.14	Not reported
Okeke (2020) (32)	Nigeria	within outpatient department of hospital	Informal caregivers Mean age: 41.1 years Age range: 18 to 75 years Sex: Female, Female 179 (57.6%) Employment: Not reported	311	Stroke	Parents 100 (32.1%) Children 18 (5.8%) Spouse 106 (34.1%) Non relatives 18 (5.8%) Other relatives 69 (22.2%)	1 to 3 months 112 (36%) 4 to 6 months 26 (8.3%) 7 to 12 months 22 (7.1%) 13 to 24 months 32 (10.3%) More than 24 months 119 (38.3%)	
Ohaeri (1999) (33)	Nigeria	Outpatient	Informal caregivers Mean age: 35.6 Age range: 18 to 75 years Sex: Not reported Employment: Employed 52 (70.4%), Unemployed 21 (29.6%);	73	Cervix cancer Breast cancer	Husband 24 (32.9%) Child 36 (49.3%) Others: 13 (17.8%)	Not reported	Daily contact with patient 55 (75.3%)
Ogunmodede (2019) (34)	Nigeria	Not institutionalised	Primary caregivers [1(1%) paid carers, 99 (99%) ICGs] Mean age: 46.5 years Age range: ≤20 to >60 years Sex: Female 56 (56.0%)	100	Type 2 Diabetes Mellitus	Parents 10 (10.0%) Child 40 (40.0%) Spouse 34 (34.0%) Siblings 11 (11.0%) Unrelated 1 (1.0%) Others 4 (4.0%)	Not reported	Daily contact 83 (83.0%) Weekly contact 10 (10.0%) 2-3 times a month 5 (5.0%) Several times a year 2 (2.0%) Number of contact hours <= 5hours: 4 (4.0%)

			Employment: Employed 66 (66.0%), Unemployed 34 (34.0%)					6-10 hours: 18 (18.0%) 11-15 ours 22 (22.0%) >16 hours 31 (31.0%)
Muriuki (2023) (50)	Kenya	Outpatient clinic	Family caregivers Mean age: Not reported Age range: 18 to >61 years Sex: Female 147 (57.6%) Employment: Employed 109 (42.8%), Unemployed 146 (57.3%)	255	Cancer (not specified)	Not reported	at least 2 weeks	Not reported
Muliira (2019) (57)	Uganda	Mixed (both out and inpatients)	Family caregivers Mean age: 36 years Age range: 18 to >51 years Sex: Female 208 (73.2%) Employment: Employed 161 (56.7%), Unemployed 123 (43.3%)	284	Breast cancer (18.3%), cervix cancer (12.3%), and leukaemia (12.3%) and others (cancers of oesophagus, prostate, ovary, pancreas, stomach, Lymphomas, and multiple myeloma).	Spouse 57 (20.1%) Child 110 (38.7%) Others 117 (41.2%)	7-11 months 135 (47.5%) 12-24 months 91 (32.1%) ≥25 months 58 (20.4%)	≤48 hours/week 57 (20.1%) 49-120 hours/week 92 (32.4%) ≥121 hours/week 135 (47.5%)
Mthembu (2016) (41)	South Africa	Not reported	Informal caregivers Mean age: 58.5 years Age range: 24 to 79 years Sex: Female 5 (83.33%) Employment: Not reported	6	Lung Disease Hypertension Stroke Diabetes mellitus	Spouse 2 (33.33%) Children 3 (50%) Other relatives (Daughter in Law) 1 (16.67%)	Not reported	Not reported
Mlaba (2021) (43)	South Africa	Mixed	Informal caregivers (<i>patients of 3 (15%) of IGCs had died</i>) Mean age: 55.05 years Age range: 21 to 84 years Sex: Female 14 (70.0%) Employment: Not reported	20	Various cancers (Not specified)	Spouse 7 (35.0%) Offspring/children 5 (25.0%) Parent 1 (5.0%) Other relatives 7 (35.0%)	Not reported	Not reported
Mlaba (2020) (42)	South Africa	Mixed	Informal caregivers (<i>patients of 3 (15%) of IGCs had died</i>) Mean age: 55.05 years Age range: 21 to 84 years Sex: Female 14 (70.0%) Employment: Not reported	20	Various cancers (Not specified)	Spouse 7 (35.0%) Offspring/children 5 (25.0%) Parent 1 (5.0%) Other relatives 7 (35.0%)	Not reported	Not reported
Mensah (2021) (66)	Ghana	Not reported	Husbands of women with advanced breast cancer Mean age: Not reported Age range: 34 to 55 years Sex: Female 0 (0%) Male 15 (100%) Employment: Employed 15 (100%)	15	Breast cancer	Husband 15 (100%)	4 to 11 months	Not reported
Mekonnen (2020) (61)	Ethiopia	Not reported	Parents of children with cancer Quantitative Mean age: Not reported Age range: 18 to >49 years Sex: Female 145 (52.7%) Employment: Not reported Qualitative Mean age: Not reported	295 (Quant itative = 275; Qualit ative = 20)	Cancer (Not specified)	Quantitative Parents 275 (100%); and Qualitative Parents 20 (100%)	Qualitative (n=275) 1-3 weeks 14 (5.1%) 4-6 weeks 148 (53.8%) 7-9 weeks 64 (23.3%) ≥10 weeks 49 (17.8%)	Not reported

			Age range: 36-45 years Sex: Female 13 (65%) Employment: Not reported					
Masuku, (2018) (44)	South Africa	Home	Primary caregivers Mean age: 38 years. Age range: 21 to 65 years Sex: Female 14 (100%) Employment: Employed 6 (42.9%), Unemployed 8 (57.1%)	14	stroke	Children 5 (35.7%) Other relatives 1 (7.1%) Wife 6 (42.9%) Sister 2 (14.3%)	RANGE (3 months to more than 3 years) <= 6 months 6 (42.9%) 7 months to <= 12 months 3 (21.4%) >12 months to <= 24 years 3 (21.4%) 24 months to 48 months 2 (14.3%)	Not reported
Masika (2020) (62)	Tanzania	Admitted	Guardians of children Mean age: 38 years Age range: Not reported Sex: Female 15 (68.2%) Employment: Not reported	22	leukemia (5), eye cancer (5), cancer of the glands (5), kidney cancer (2), stomach cancer (1), thyroid cancer (1), and liver cancer (1)	Guardian 22 (100%)	Not reported	Not reported
Marima (2019) (49)	Zimbabwe	Outpatients	ICGs Mean age: 41.5 years Age range: Not reported Sex: Female 50 (70.4%) Employment: Not reported	71	Stroke	Not reported	Median (IQR) 4 (2-13) months; Most had provided care for at least 4 months	Not reported
Maree (2018) (11)	South Africa	Not reported	Primary ICGs Mean age: 41.7 years Age range: 20 to 65 years Sex: Female 10 (50%) Employment: Not reported	20	various cancers (Not specified)	Children: 10 (50%) Spouse: 4 (20%) Friends/non-related: 3 (15%) Other relatives: 2 (10%) Sibling: 1 (5%)	Between 3 weeks and 10 years, with an average of 24.8 months (SD ± 26.9).	Not reported
Kitoko (2022) (52)	Democratic Republic of Congo	Outpatients (follow-up visit to rehabilitation centre)	ICGs Mean age: 42.3 years Age range: Not reported Sex: Female 58 (68.2%) Employment: Employed: 54 (63.5%); Unemployed: 31 (36.5%)	85	Stroke	Not reported	At least 3 months	Not reported
Khondowe (2007) (68)	Zambia	Outpatients	Caregivers of stroke outpatients	10	Stroke	Not reported	Not reported	Not reported
Ketlogetswe (2022) (45)	South Africa	Hospice admitted patients	Primary ICGs Mean age: 52 years Age range: 23 to 84 years Sex: Female 19 (86.36%) Employment: Employed: 10 (45.45%); Unemployed: 12 (54.54%)	22	cancers of head, neck, prostate, thyroid, breast, lung, vulva, & blood	mostly mothers of the sick person, but also included partners, sons, daughters and a neighbour (No statistic given)	13 months on average	Not reported
Katende (2017) (60)	Uganda	inpatients and outpatients	Family caregivers Mean age: 33 years	119	Cancer (Not specified)	Parent: 32 (26.9%) Other 1st degree	Not reported	Not reported

			Age range: 18 to 60 years Sex: Female 80 (67.2%) Employment: Employed: 73 (61.3%) Unemployed: 46 (38.7%)			relatives: 49 (41.2%) Extended family: 32 (26.9%) Other: 6 (5.0%)		
Jones (2012) (28)	Tanzania	At their home	Primary ICGs of physically dependant stroke survivor Mean age: 47 years Age range: 16 to 73 years Sex: Female 23 (85.19%) Employment: Employed: 17 (63.00%), Unemployed: 10 (37.00%)	27	Stroke	Children: 14 (51.85%) Spouse:11 (40.74%) Grand children: 2 (7.41%)	At least 6 months	Not reported
Gertrude (2019) (21)	Uganda	admitted in hospital	ICGs Mean age: Not reported Age range: 18 to ≥55 years Sex: Female 14 (56%) Employment: Employed: 21 (84%%), Unemployed: 4 (16%)	25	STROKE: Ischaemic stroke: 15 (60%) Haemorrhagic stroke: 8 (32%) Stroke (type Missing): 2 (8%)	Spouse: 9 (36%) Child/Child in law: 9 (36%) Other: 7 (28%)	4 months to 1 year: 10 (40%) ≥1 year: 15 (60%) (Median duration of care:16 months)	Not reported
Gbiri (2015) (35)	Nigeria	Physiotherapy Out-patient Clinics	ICGs assisting with ADL Mean age: 39.2 years Age range: 17 to 74 years Sex: Female 76 (48.4%) Employment: Employed: 105 (66.9%); Unemployed: 52 (33.1%)	157	Haemorrhagic stroke 61 (38.9%) Ischaemic stroke 96 (61.1%)	Children: 75 (47.8%) Spouse:45 (28.7%) Children: 21 (13.4%) other significant others: 16 (10.2%)	At least 1 month	Below 6 hours: 57 (36.3%) 6–12 hours: 82 (60.5%) > 12 hrs: 18 (11.4%)
Gawulayo (2021) (46)	South Africa	Not reported	Family Caregiver assisting with ADL Mean age: 48 years Age range: 33 to 84 years Sex: Female 5 (62.5%) Employment: Employed: 2 (25%); Unemployed: 6 (75%)	8	Stroke	Tertiary: 1 (12.5%) Secondary: 7 (87.5%)	At least 6 months	Not reported
Esmaili (2018) (63)	Tanzania	Not reported	Caregiver children with cancer Mean age: Not reported Age range: Not reported Sex: Female 11 (55%) Employment: Not reported	20	Hepatoblastoma (3), Kaposi's sarcoma (3), Osteosarcoma (3), Wilms tumor (3), Chronic myelogenous leukemia (2), Nephroblastoma (2), Chondroid sarcoma (1), Neuroblastoma (1), Non-Hodgkin lymphoma (1), Retinoblastoma (1)	Not reported	Not reported	Not reported
Duru (2021) (36)	Nigeria	Outpatients	Parents of children with Congenital Heart Disease (CHD) Mean age: Not reported Age range: Not reported Sex: Not reported Employment: Not reported	121	Acyanotic congenital heart diseases (79.3%), Cyanotic congenital heart (20.7%)	Mothers 84.3%; Guardians 10.7%; Fathers 5.0%	At least 3 months	Not reported
Dhada (2019) (47)	South Africa	Outpatients	ICGs of children Mean age: 38 years Age range: 20 to 67 years Sex: Female 14 (100%)	14	Diabetes Mellitus	Mother: 9 (64%) Aunt: 3 (22%) Grandmother: 2 (14%)	• The mean duration of each caregiver's experience of caring for a child	Not reported

			Employment: Employed: 2 (14%); Unemployed: 12 (86%)				with DM was 3.4 (±2.6) years, with a range between 5 months and 10 years • Diabetes caregiving years (total): 47.4	
Dawson (2020) (67)	Ghana	Inpatient	Primary family caregivers Mean age: 40 years Age range: <30 to >50 years Sex: Female 120 (76.9%) Employment: Employed: 130 (83.3%) Unemployed: 26 (16.7%)	156	Lymphoma	Auntie/Uncle: 13 (8.3%) Parent: 108 (69.2%) Grandparent: 19 (12.2%) Sibling: 16 (10.3%)	at least 1 month	Mean care hours/ month 52.3 About 56.8 and 54.0 hours per month are spent by carers in the private sector and self-employed (respectively) assisting patients with daily activities. Average time spent by those unemployed is 53.3 hours.
Bessa (2012) (48)	Togo	Not reported	ICGs Mean age: 43 years Age range: 30 to 65 years Sex: Female 14 (82%) Employment: Employed: 7 (41%) Unemployed: 10 (59%)	17	Cancer (Not specified)	Siblings: 5 (29%) Spouse: 4 (24%) Children: 3 (18%) Parent: 2 (12%) Relatives: 2 (12%) Friends: 1 (6%)	9 (53%) had been caring for a loved one between 4 and 12 months prior to the study	
BeLue (2018) (59)	Senegal	Outpatients	Family caregiver Mean age: 39.7 years Age range: 20 to 92 years Sex: Female 10 (52.6%) Employment: Not reported	19	Diabetes mellitus	Children: 7 (36.8%) Spouse: 4 (21.1%) Sibling: 2 (10.5%) Others: 6 (31.6%)	Not reported

203 Quality of the included studies

204 Overall, the included articles were of good quality as shown in Table 2. More than three-quarters
 205 (83%) of these articles met at least four of the five criteria. In two articles (33,55), only two of
 206 the five criteria were met. The weaknesses of the quantitative articles were predominantly related
 207 to the failure to report or justify the sampling strategy, sample size and risk of nonresponse bias.
 208 All the qualitative articles met at least four of the Mixed Methods Appraisal Tool (MMAT)
 209 criteria except one (25) where three of the five criteria were met.

231

232

233 **Participants characteristics**

234 In this review, two (4.3%) of the 47 articles had samples with paid caregivers forming part of the
235 population, although in small proportions. That is, they made up 8.8% (7/80) of the sample in
236 one article (27) and 1% (1/100) in the second article (34). Similarly, caregivers whose care
237 recipients had died formed part of the sample in two articles (42,43). For each study, these
238 caregivers accounted for 15% of the respective samples. There was no study with a comparison
239 group. Also, ten articles (29,30,32,34,38,49,52,56–58) (41.7% of the quantitative articles) noted
240 that they excluded ICGs who had any of the outcomes of interest prior to assuming the caregiving
241 role.

242 The majority of caregivers were either parents, siblings, children, spouses or other relatives of
243 the patient and their ages ranged from ten (31) to ninety-two years (59). The proportion of non-
244 familial caregivers was less than 10% in each of the seven (14.9%) articles
245 (27,32,34,37,45,48,60) where they were part of the sampled populations. In 19% (9/47) of the
246 articles (12,36,47,51,58,61–64), the participants were caregivers of children with chronic
247 diseases. More than half of the articles (53.2%, 25/47) focused on caregivers of people with
248 cancers (9,11,12,29,31,33,37,39,42,43,45,48,53,54,56–58,60–67). The rest of the articles
249 studied caregivers of people with cardiovascular diseases (21,25–
250 28,30,32,35,36,38,40,44,46,49,52,55,68) (36.2%, 17/47) and diabetes mellitus (34,47,51,59)
251 (8.5%, 4/47). There was no study with caregivers of people with chronic obstructive pulmonary
252 disease. Generally, there were more female participants than male participants. However, in just
253 five (10.6%) of these papers (29,35,56,64,66), the proportion of females did not reach at least
254 half of the total participants. The characteristics of the included studies and participants are
255 summarised in

256 **Table 1.**

257 **Activities performed by ICGs**

258 The roles performed by caregivers were described in two-fifths (20/47) of the included articles.
259 With the exception of one (45), these articles listed the various things caregivers did. In this
260 article, the authors simply stated that performed activities of daily living were demanding and
261 exhausting but did not specify what tasks they were.

262 In this review, we have grouped informal caregivers' activities into three activities.

263 i. Basic activities of daily living

264 These are personal care tasks that are important for one's everyday living. The ICGs played a
265 critical role in supporting care recipients with personal care activities like bathing and dressing
266 (9,11,21,25,35,40,41,48,54,66,68), toileting (21,48) and feeding (21,25,64). They also assisted
267 with functional mobility activities that support the patient to move in and out of bed,
268 repositioning, ambulating and moving up/down the stairs (21,25,35,40,48).

269 ii. Instrumental activities of daily living

270 These activities were quite diverse and included caring for the patient's children (40), shopping
271 for the patient (11,68) and doing domestic tasks (house chores) like room cleaning, making
272 meals, laundry and washing utensils (9,11,25,36,40,46,48,54,59,66). The caregivers were
273 actively involved in the health management of their sick loved ones by managing medical
274 appointments and transporting the patient to hospital (9,11,21,25,36,42,46,47,53,59,62,64,68),
275 communicating with health workers on the patient's behalf (9), paying medical expenses
276 (9,21,35,36,42,47,48,59,62,63), providing company and psychological support to patient
277 (9,21,59,62) and monitoring the patient's symptoms (11,47,66).

278 iii. Medical activities

279 The ICGs performed activities that would ideally require a certain level of medical training,
280 experience or knowledge. Eight articles (9,11,21,25,40,41,59,66) highlighted specific medical
281 procedures that were done by the ICGs. These included changing colostomy bags, wound
282 dressing, helping patient use oxygen breathing apparatus and administering both oral and
283 injectable medications for the patient. Despite performing these tasks, the ICGs acknowledged
284 their lack of knowledge and skills. This was clearly articulated by one caregiver: "*To be honest*
285 *I cannot say I have been doing a great job of caring for my father....it is just a 'trial and error'*
286 *situation. It feels like I am not doing enough. Somehow, I feel like giving up...*"(45).

287 **Reasons/motivation to provide care**

288 The reasons for taking up caregiving roles were recorded in six (12.8%) papers
289 (11,21,25,45,48,64), all of which were qualitative studies. From their submissions, it was clear
290 that the decision to provide informal care depended on two things; how related or connected the
291 ICG was to the patient and the ICG's level of responsibility (social obligation) over the patient.

292 i. Relationship between the caregiver and the patient

293 Regarding the relationship (or connectedness) to the patient, ICGs narrated how they provided
 294 care because of the love that existed in their relationship either as family members, neighbours
 295 or friends (21,48). Because of this bond (and feeling of belonging), they willingly volunteered
 296 and often considered themselves the most suitable persons to care for their loved ones. The
 297 closeness of the relationship between the caregiver and recipient is a strong motivator for
 298 becoming a caregiver. This view was echoed by a Togolese caregiver who was quoted saying,
 299 *“The problem is that nobody can take care of my mother as I am doing it. If something does not*
 300 *belong to you, you treat it differently.”* Another participant in the same study added, *“I see myself*
 301 *in a better position to do the care work because I know her very well.”* (48).

302 ii. Level of responsibility the caregiver has over the patient.

303 Quite relatedly, the ICGs also viewed their decision to care as a form of responsibility or a social
 304 obligation (11,25,45,48,64). They naturally took on the role and were as committed in the work
 305 as they would in any other professional job. They considered caring as a duty they were obliged
 306 to perform against all odds for those they were socially expected to support. One mother
 307 explained how she had to take her older child (with cancer) to the hospital despite her own poor
 308 health: *“I remember there was a time I sat in a chair by the bedside throughout the night and my*
 309 *legs got swollen...it was not easy, but I passed through all that. When I gave birth on Thursday,*
 310 *the following Tuesday I had to bring my sick son to the hospital for review...I had to do it.”* (64)

311 **Impact of caregiving on the caregiver**

312 All studies had an aspect of the impact (health or economic) caregiving had on the carers. In this
 313 section, results on how the impact was measured, positive impact of caregiving, economic impact
 314 of caregiving and health impact of caregiving was provided. These are also summarised in Table
 315 3

316 **Table 3. Table showing the results identified in the included articles**

Results	Sub-heading	Studies
Activities done by caregivers (20 studies)	Basic activities of daily living	(9,11,21,25,35,40,41,48,54,64,66,68)
	Instrumental activities of daily living	(9,11,21,25,35,36,40–42,46–48,53,54,59,62–64,66,68)
Motivation to become an ICG	Relationship between the caregiver and the patient	(21,48)
	Level of responsibility the caregiver has over the patient	(11,25,45,48,64)
	Positive impact of caregiving on ICGs	(41,59)
	Economic impact of caregiving	1. Cost of caregiving (9,25,36,40,48,55,63,67)

Impact of caregiving		<ol style="list-style-type: none"> 2. Work-related effects of caregiving (9,11,12,21,25,26,40–42,44–48,50,55,59,62,64,66,68) 3. Financial challenges (11,26,27,31,33,35–37,39,40,42,45–47,50,62–64,66–68)
	Health impact of caregiving	<ol style="list-style-type: none"> 1. Impact on the physical health of ICG (21,25,30,35,38,40,43,45,48,50,54,64) 2. Impact on the mental health of ICG (21,25,28,29,32,34,40,43–45,47–49,51,52,55–62)

317

318 **Measurement of the impact of caregiving**

319 From the findings, about half of the articles (22/47) used standardised tools/instruments to
 320 determine the impact of caregiving. It was only the qualitative papers and one quantitative paper
 321 (36) where no standardised instrument was used in measuring the impact of caregiving. The tools
 322 (in their original or modified form) used include, the Zarit Burden Interview (ZBI) questionnaire
 323 (29,31,32,34,35,37,39,52,55,67), the Hospital Anxiety and Depression Scale (HADS)
 324 (28,52,57,60), Caregiver strain index (CSI) (26,27,35,50), Nordic Musculoskeletal
 325 Questionnaire (NMQ) (30,38), General health questionnaire (GHQ) (29,33,34), Patient Health
 326 Questionnaire-9 (PHQ-9) for Depression (56) Caregiver Reaction Assessment scale (CRA) (57),
 327 Beck's depression inventory (BDI) scale (61), Shona Symptoms Questionnaire (SSQ) (49), The
 328 modified Rankin scale (mRS) (52), Depression, Anxiety, Stress Scale-21 Items (DASS-21) (51)
 329 EUROHIS QoL (67), Modified version of the Frankfurter Befindlichkeit Skala (FBS) (33) and
 330 Hopkins Symptom Checklist (HSCL-25) tool (58). Two studies (36,67) used cost of illness
 331 approaches to estimate the direct and indirect costs incurred by the caregivers who supported
 332 people with chronic diseases.

333 **Positive impact of caregiving**

334 Although the focus of most articles was on the negative impact of caregiving, two articles (41,59)
 335 in particular had caregivers who described how rewarding the activity was to them. They
 336 commented on how the situation strengthened the bond with the person being cared for, thus
 337 enabling them to develop the dedication and emotional strength to continue caring. Furthermore,
 338 the practice of caring became a strong motivation for improvement of their own health (59).
 339 Whenever they saw how their loved ones suffered, they felt energized to do whatever was
 340 necessary to avoid getting the same disease. They became motivated to adopt a healthier lifestyle
 341 that included having regular medical check-ups, doing more exercises and taking healthier meals.

342 Because of their involvement in the day-to-day management of the care recipients, they acquired
343 skills and knowledge to protect themselves from acquiring the disease and to fulfil the care needs
344 better. For example, one caregiver who was always there whenever the doctor came to treat his
345 wife stated that, “*my experience helps a lot to avoid diabetes in my own life. What the doctor*
346 *says to my wife, I also apply to my own life because that is good for everyone, not just the diabetic*
347 *patients.*” (59)

348 **Economic impact of caregiving**

349 There were three key findings under economic impact, and these were the cost of caregiving, the
350 work-related consequences of caregiving and the subsequent financial challenges arising from
351 caregiving.

352 i. Direct costs of caregiving

353 Surprisingly, only 4 articles (36,48,55,67) provided information on the cost of caregiving on the
354 caregiver. Of these, only 2 articles gave an estimate of the overall cost of providing informal
355 care. According to the studies by Dawson *et al* (67) and Duru *et al* (36), the monthly mean cost
356 of caregiving for each patient was US\$440.32 (SD: US\$205.75) and US\$ 20.36 ± US\$ 27.82,
357 with direct costs accounting for 97% and 81% of the total costs respectively. The only
358 information on the costs of care that Bessa *et al* provided was the average monthly money (US\$
359 66 monthly (range = US\$ 21 – US\$ 213)) spent by ICGs on their loved ones with cancer (48).

360 Two articles (36,55) discussed the monetary value of the productivity loss incurred by ICGs
361 while providing care. The mean productivity loss incurred by caregivers in Duru *et al*'s study
362 (36) was \$53.42 ± \$88.12 (range US\$1.38 to US \$ 575.00) while those in the study by Ababacar
363 *et al* (55) experienced a financial loss of 206.92 USD (SD: 583.16 USD) (range: 0 to 3103.44
364 USD).

365 ii. Social cost of caregiving

366 Of note, are the 4/47 articles (9,25,40,63) that commented on the social cost associated with
367 informal caregiving. Opportunity cost refers to the cost of foregoing other rewarding activities
368 in order to support a sick loved one. As one ICG put it, caregiving “*restricts our lives*” (40)
369 giving them little room for engagement in other activities. A female ICG in Cameroon
370 commented on the cost involved in letting go of her previously planned activities. She stated,
371 “*Since my mother is in this state, [...] I am obliged to suspend my participation in the church*

372 *every morning as I did before because it is no longer possible! I had to review all my activities*
373 *because I had to find time for my mother! It's painful but I do it!" (25).*

374 While some caregivers had to let go of their regular leisure activities (25), others especially the
375 students ended up missing attending classes at school (40).

376 iii. Work-related consequences of caregiving

377 In 21 (44.7%) studies, there is a clear demonstration of how caregiving affected all aspects of
378 one's work life (regular source of income). Since caring often required one's physical presence,
379 the caregivers not only used up all the available work leave (including taking leave without pay)
380 but they were also frequently absent (without permission) from work. This resulted into being
381 queried, warned, sanctioned and in other cases dismissed (9,11,48,64,66). In the study by
382 Ababacar et al. (2022) (55) the caregivers were off work for an average of 23.86 days (SD 64.53
383 days) per year with extremes ranging from 0 to 365 days.

384 The participants admitted that they struggled to maintain a balance between work and caregiving
385 roles (9,11,21,41,48,59,66,68). This made them less efficient (productive) at work and unable to
386 meet several deadlines because they frequently arrived late for work, spent less time doing work
387 and struggled to concentrate while at work (12,25,42,48,66). This situation was well explained
388 by the caregiver who said, "*There was a piece job that I had in Durban, it was affected because*
389 *I had to be here in Pietermaritzburg to take care of her [my mother]. I couldn't stay [at work]*
390 *for the week and come back on the weekend or month end, I had to keep coming back here [to*
391 *check on my mother]."* (42)

392 As such, they had to make work-related adjustments that would allow them to attend to their sick
393 loved ones too. Part of the adjustments included getting a flexible work schedule that allowed
394 them to work either at night or from home (26,44,50,55) and changing to temporary self-
395 employment or to jobs that are flexible and closer to the patient's home (42,46,55). In cases
396 where the caregivers could not maintain both work and caregiving roles, they either voluntarily
397 resigned or were dismissed from work (9,11,12,21,40–42,45–48,55,62,64,66).

398 iv. Financial challenges arising from caregiving.

399 There were 21 (44.7%) articles in which caregivers reported experiencing financial challenges.
400 First, they stated that they lost money and their sources of income through covering high medical
401 expenses and loss of jobs (31,33,36,42,45,63,64). Their response to such challenges included
402 taking loans to get money to care for the patient (33,63,64,66,67), seeking additional financial

403 support from relatives and institutions like churches (62,67), sale of family properties (62,64,66)
404 and requesting for premature discharge from the hospitals (63).

405 In cases where resources to cover the expenses were inadequate, the ICGs compromised their
406 standard of living, forewent paying house rent, paying their children's school fees as well as
407 buying food and clothes in order to meet their patient's care needs (9,63). As a result, some were
408 reportedly thrown out of their house due to non-paid rent.

409 Overall, caregivers felt that caring was financially burdensome causing them to be in a much less
410 satisfactory financial status than before taking up the role
411 (11,26,27,35,37,39,40,42,46,47,50,66,68). They described their financial situation as being
412 unstable, strenuous and hard, and they often became anxious whenever they thought about where
413 to get more money to continue with their role (35,46,47). Quantitatively, the prevalence of
414 caregivers experiencing financial strain ranged from 37.9% to 100% (26,27,37,50).

415 **Health Impact of caregiving**

416 Caregiving affected the physical health and mental health of the carers as stated below.

417 i. Physical health consequences of caregiving

418 This was found in twelve articles (21,25,30,35,38,40,43,45,48,50,54,64). The development of
419 new medical conditions and or worsening of existing health conditions among the ICGs affected
420 their physical health and reduced their ability to adequately care (35,64). Some attributed this to
421 lowering of the body's immunity (40) that occurred while providing care. They stated that they
422 developed new medical conditions such as hypertension, headache, body pains and swelling of
423 the feet during the period they provided care to the patient (21,45,64). One caregiver even
424 narrated a life-threatening incident that necessitated hospitalization "*...after collapsing while*
425 *fetching water for the sick son*" (64). There were also reports of the worsening of the caregivers'
426 own health condition (21,30,38,45,48,54,64). The articles show how those with musculoskeletal
427 complications such as pain in upper and lower back, pain in different joints (shoulder, wrist, hips,
428 buttocks, knees, ankle and elbow joint), and pain in the thighs, neck and feet complained of
429 deteriorating health. This was well articulated by a caregiver whose waist problem worsened
430 while caring for her husband. She stated; "*Caring for my husband is not easy; I have a waist*
431 *problem, and I find myself always very tired. The waist problem was there but was not as serious*
432 *as it has become now, all because of the role I currently play*" (54).

433 The caregivers in 10 studies experienced significant lifestyle changes during their work. They
434 felt that their sleep was disturbed because of actual/anticipated care demands, and severity of the
435 condition of the person they cared for (64). They experienced disruption from sleep, feeling of
436 lack of enough sleep, feeling like they are deprived of sleep as well as short episodes of sleep
437 (25,43,45,50,54,64). Another way caregiving affected their lifestyle was through change in
438 eating habits. This involved either changing the meal time in order to incorporate the caregiving
439 demands/activities, eating the patient's left over foods or missing the meals due to the lack of
440 money/ time (54,64). A male carer commented on his changed lifestyle by saying, "*It [life] has*
441 *changed because I hardly sleep now, I just think that I can't sleep I have to constantly check on*
442 *him.*" (43)

443 ii. Mental health consequences of caregiving

444 The act of caregiving had a profound effect on the mental wellbeing of care providers as stated
445 in more than half (23) of the articles (21,25,28,29,32,34,40,43–45,47–49,51,52,55–62).

446 Although most of these articles described the different types of mental health challenges, five
447 (29,34,49,55,58) did not specify as they only used the terms "psychological" and "psychiatric"
448 challenges. Using GHQ (29,34), SSQ (49), HSCL-25 (58) and ZBI (29,34,55) tools, the reported
449 prevalence of psychological/psychiatric challenges among caregivers ranged from 35% to
450 66.7%.

451 The caregivers experienced mild to severe forms of depression as was assessed using HADS
452 (28,52,57,60), ZBI (32), PHQ-9 (56), BDI (61) and DASS-21 (51) tools. From these eight
453 quantitative studies, the prevalence of depression ranged from 26% to 72.4%. In addition, there
454 were two qualitative studies with ICGs who reported feeling depressed because of the caregiving
455 work (25,40). Some got to an extent of being treated for depression as explained by this South
456 African ICG: "... *I also get sick often. I have continuous lung infections from stress. I'm on*
457 *antidepressants as well.*"

458 Fear, stress and anxiety is another mental health related challenge that caregivers in 9 studies
459 (28,45,47,51,52,57,59,60,62) reportedly experienced. There was no quantitative paper in which
460 fear or stress was investigated. Instead, five quantitative papers employing HADS (28,52,57,60)
461 and DASS-21 (51) tools found that the prevalence of anxiety among ICGs ranged from 21.6%
462 to 45%. Sometimes, the ICGs thought about the likelihood of acquiring the same illness their
463 loved ones have or death of those they care-for. Such thoughts caused fear, stress and anxiety
464 among the ICGs (45,59). This challenge was most felt in the initial stages of caring for the

465 patient, when there was a lot of work to be done and when the activities were complex (47).
466 While one caregiver hinted at how hard some caregiving activities can sometimes be by saying,
467 *“the hardship is just injecting the child part, it’s not something that’s easy—it’s not easy –*
468 *because sometimes you find that the child does not want to be injected...when her sugars are*
469 *high and you try to inject her – she says ‘you’re injecting me a lot’.”(47)*

470 Another expressed the fear that comes with such activities: *“... The family members you stay*
471 *with do want to assist with injecting the child but they are scared – so sometimes you’re the only*
472 *one who’s taking care of the child.” (47)*

473 Five quantitative articles (28,51,52,57,60) explored the prevalence of anxiety among caregivers
474 and found it to be in the range of 21.6% to 45%.

475 Caregiving was also described as an emotionally challenging activity by participants in four
476 studies (25,44,45,48). They used phrases such as being morally sick, emotionally painful,
477 heartbreaking, emotionally touched, burdens me, disturbed and hopelessness to show their
478 reaction to caring for the sick or the diagnosis given. The extent of suffering that caregivers
479 observed their loved ones go through was enough to create feelings of preferring to *“isolate*
480 *[oneself] to cry”* and develop thoughts of *“not ... living anymore”* (44,48). Caregivers confessed
481 that such reactions also followed the sudden announcement (by the medical team) of the type
482 disease their loved one was suffering from (25). One participant whose husband had been
483 diagnosed with cancer recalled such a moment: *“It was painful, wena [‘you’ – exclamation]. You*
484 *... you know that person is a breadwinner and everyone in his family is looking up to him. He is*
485 *supporting everyone. Then it was painful, but I think that I am recovering now.” (44)*

486

487 **Discussion**

488 In this review, we found a total of 47 qualitative and quantitative studies from across the sub-
489 Saharan African region that were published over a period of more than two decades.

490 **Reasons of becoming an ICG**

491 These studies show that a relationship that is strengthened by love and the sense/feeling of
492 responsibility over an individual appear to be the most important factors in the decision to

493 provide care. This finding is consistent with those in other reviews with studies from across the
494 world (17,69). In our review, children as young as ten years of age also participated in providing
495 care to people with chronic diseases. This can be explained by how responsibilities/activities are
496 shared or delegated in many African multi-generational homes (29,70). Often, children are
497 assigned the task of providing care for unwell or elderly relatives while adults participate in
498 income generating activities (29,70). Once assigned the tasks, the children take them as their
499 responsibility. The finding from this and other reviews (17,69) may mean that the reasons for
500 becoming caregivers may not be very different across the world even with varying cultures and
501 traditions.

502 **Activities performed by ICGs**

503 The caregivers, majority of whom were female and were related to the patient, performed a wide
504 range of activities during their caregiving role. Perhaps the most striking finding is that
505 caregivers did not end at performing the common/regular tasks like support with feeding and
506 with personal care needs, but they did complex activities including changing colostomy bags and
507 administering injectable medication which normally require medical skills/training to do well.
508 This rather interesting finding points to shortage of health workers in most settings in SSA. In
509 most cases, the ICGs end up performing these tasks when health professional cannot be accessed
510 (71,72). The implication of such findings is the possibility of ICGs making numerous mistakes
511 while conducting procedures they were not trained to perform and unknowingly endangering
512 themselves and/or those under their care. A recent review conducted in one of the SSA countries
513 had findings similar to ours (16). In their study, the caregivers were mainly females, relatives of
514 the patient and performed most activities as described in our work. The only noticeable
515 difference is that there was no mention of the activities, that we have described as complex. This
516 is possibly because their study either considered diseases (such as HIV) that are rarely
517 complicated by events like surgery which may require changing colostomy bags and wound
518 dressing or the diseases had not yet gotten to a level that required interventions like use of oxygen
519 therapy or administration of injectable medications.

520 **Impact of caregiving on the ICGs**

521 To measure the impact of caregiving, almost all quantitative studies used a standardised
522 instrument/tool. As shown in the results, a total of 14 different tools were used in the 22 studies
523 to assess the burden of depression, anxiety, stress and financial strain. Even in the studies where
524 the same tool was used, the results were presented differently. For example, in the studies that

525 used Zarit burden Interview (ZBI), two (29,32) reported the overall mean ZBI scores while the
526 rest provided mean scores of each category of burden. This lack of uniformity in the use of
527 measures and presentation of results make it difficult to compare different studies' results. In this
528 review, ZBI tool was the most used instrument for measuring the impact of caregiving. It was
529 used in 10 out of the 22 articles assessing the health or economic impact using an instrument.
530 This accords with earlier observations from another review which found that ZBI was the most
531 frequently used tool in measuring the burden of caregivers (73).

532 As discussed in the next three paragraphs, caregiving had both positive and negative effects on
533 the ICGs. As expected, there were more articles focussed on the negative than positive impact
534 of caregiving.

535 The rewards experienced by informal caregivers in this review can be explained by the post-
536 traumatic growth (PTG) theory which suggests that people facing traumatic or challenging events
537 may experience some positive outcomes from their experience (74). Caring for people, some of
538 whom are at an advanced stage of a chronic disease can be stressful and traumatic due to the
539 highly demanding nature of the caregiving tasks. Such situations often prompt ICGs to do self-
540 reflection leading to the discovery of new and positive insights as well as renewed purpose for
541 living under the current conditions. A number of recent studies have used this theory to
542 demonstrate how caregivers' challenging experiences resulted in positive outcomes like renewed
543 personal strength to continue in their caring role, strengthening of the relationship with care
544 recipients/family members and taking better care of their own health because they better
545 appreciate life (75–77).

546 As with other reviews (15,16) conducted in SSA, caregivers with a regular source of income
547 faced work-related challenges such as absenteeism, dismissal from work and low productivity
548 as already listed in the results section. Caregivers' involvement in extensive physical work like
549 assisting patient with mobility-related activities may result into injuries and exhaustion.
550 Depending on the patient's care needs and severity of the disease, the caregivers may spend a lot
551 of time with the patient. Under such circumstances, the caregivers will either fail to go to work
552 or arrive late at work leading to reduced productivity and conflicts at work. The exhaustive nature
553 and emotional burden that comes with caring for loved ones also reduces one's level of
554 concentration and performance while at work. In the end, caregivers are often dismissed or forced
555 to resign from their work. At times, they sought employment in places with work that suited their
556 caregiving responsibilities such as self-employment, temporary employment or jobs with flexible
557 working hours (78). It is also worth noting that a disrupted career/job has the potential of causing

558 significant financial strain on the career, hinder career progression and affect retirement
559 planning. These are likely to persist even after they are no longer providing care.

560 As would be expected, informal caregivers experienced both physical health and mental health
561 challenges during their work. Several reviews have had similar findings published (14–17). This
562 is consistent with allostatic load theory, in which McEwen and Stellar observed that although
563 stressors usually resulted in a normal physiological response as a body's protective mechanism,
564 exposure to high and sustained stress such as that experienced by informal caregivers caused an
565 abnormal response that resulted in cumulative wear and tear of the body (79). The allostatic load
566 experienced by caregivers arises from exhaustive physical activities they do, emotional
567 challenges caused by the patient's condition and logistical stressors like financial strain. Part of
568 the abnormal response includes change in the production and levels of hormones like cortisol
569 and adrenaline which could lead to cardiovascular diseases, weakened immune system,
570 inflammation, metabolic changes (affecting an individual's appetite) and mental health diseases.

571 **Limitations of the review**

572 This review had some limitations. First, the second reviewer could only screen a proportion of
573 studies during the title and abstract screening stage and during the full text screening. Also, a
574 single author extracted the data from the included studies with the second reviewer checking the
575 accuracy of the data. A study showed that a complete dual review significantly minimised
576 random errors compared to either single review or limited dual review (80).

577 Secondly, we were unable to get all the full-texts of the conference abstracts that were included
578 in this review. While the contacts for some authors could not be retrieved, the majority of those
579 contacted either did not respond or did not have the full-texts for their abstracts available. It is
580 therefore possible that some important articles could have been missed.

581 Furthermore, some studies did not provide adequate information as some data was either unclear
582 or not reported. This includes information on sex, age and well as the impact of caregiving. This
583 limited our ability to extract all the relevant data required to comprehensively analyse the data.

584 Lastly, most quantitative studies used a cross-sectional study design making it difficult to assess
585 the cause-and-effect relationship, and to understand the changes that occur over time. However,
586 almost half of these articles excluded participants with outcomes of interest prior to starting
587 caregiving.

588 **Strengths of the review**

589 Part of the strength of this review is in the fact that we used a very broad search strategy to
590 extensively search a good number of relevant databases. We also included non-English articles.
591 These enabled us to capture as many relevant articles and information as possible. The use of a
592 second reviewer improved the reliability and quality of the findings through reducing the errors
593 and biases that could have risen if only one reviewer was involved in the review process.

594

595 **Conclusions**

596 The ICGs occupy an essential place in the health care system of most SSA countries and they
597 perform a broad range of tasks, some of which they are ill-prepared or untrained to do. The
598 growing demand for ICGs created by the increasing chronic diseases in the African continent
599 means that health care systems would function better if they are adjusted to prepare ICGs for the
600 caregiving roles, and to support the physical and mental wellbeing of ICGs. Future research
601 should investigate the most suitable tools/instruments for assessing the impact of care on the
602 caregiver.
