## 12 Abstract:

Despite declining malaria cases in Thailand, surveillance in endemic areas is crucial. Retrospectively analyzing samples from Tak province, Thailand, we found prevalent drugresistant *Plasmodium falciparum*, particularly to mefloquine and sulfadoxine/pyrimethamine. Notably, mutations indicating resistance to artemisinin were detected at low frequencies, suggesting evolving resistance. These findings stress the need for continuous surveillance to guide control strategies and prevent outbreaks, even with decreasing cases, to sustain malaria elimination efforts.

20 Keywords: PfKelch13 Mutations, GMS, Plasmodium, TAC

Malaria remains a significant public health challenge in the Greater Mekong Subregion (GMS), 21 historically serving as a hotspot for transmission by Plasmodium falciparum and Plasmodium 22 vivax. Despite progress in reducing incidence over the past decade, transmission persists in 23 border areas and remote regions with limited healthcare access (Sudathip et al., 2019). 24 25 Artemisinin-based combination therapies (ACTs) have been crucial in treatment and control efforts, but artemisinin resistance threatens progress. PfKelch13 mutations are central to this 26 resistance, altering the parasite's response to artemisinin (Ashley et al., 2014). The WHO has 27 28 identified thirteen validated PfKelch13 markers of resistance (World Health Organization, 29 2022).

The earliest documented PfKelch13 mutation linked to resistance dates to 2008, with subsequent high prevalence in *P. falciparum* isolates, especially in border regions and areas with extensive antimalarial drug use (Ménard et al., 2016). Surveillance systems, including the innovative *P. falciparum* TaqMan Array Cards (TACs), play a vital role in monitoring PfKelch13 mutations. TACs offer a high-throughput, cost-effective means of detecting genetic markers associated with *P. falciparum*, aiding large-scale surveillance and clinical trials (Pholwat et al., 2017).

Our study presents findings from a survey using TaqMan Array Cards (TACs) to assess drug-37 resistant markers in Mae Sot, Tak, Thailand, from 1998, 1999, and 2001, offering insights into 38 the prevalence and dynamics of artemisinin resistance-conferring PfKelch13 mutations, 39 enhancing understanding of malaria and drug resistance in the GMS (Figure 1). A total of 808 40 41 archived blood samples were collected during malaria studies evaluating rapid diagnostic tests 42 (RDTs) for P. falciparum in Tak Province, Thailand, conducted from 1998 to 2001. These samples were primarily assessed for both mono- and mixed P. falciparum/P. Vivax infections by smear 43 and were subjected to analysis using TACs. Out of the total samples, 112 were excluded due to 44 45 the absence of *Plasmodium* spp. or being positive only for *P. vivax*. The remaining 696 samples were confirmed to be positive for *Plasmodium* species, with *P. falciparum* being the most 46 prevalent (Table 1). 47

Using the *Plasmodium* TAC panel , mutations in several key genes associated with drug resistance and malaria biology were analyzed. These genes included PfKelch13, *P. falciparum* CQ-resistant transporter (Pfcrt), Pfdhfr, Pfdhps, cytochrome bc1, and Pfmdr1 *P. falciparum* genes (Table 2). The Pfcrt mutations at amino acids 72-76 reflect chloroquine resistance, selected for the TAC panel before the discovery of novel mutations' role in piperaquine resistance (Muhamad et al., 2013).

54 During the sample collection period, the first-line treatment for uncomplicated *P. falciparum* infection was mefloquine alone or in combination with sulfadoxine/pyrimethamine (S/P), later 55 with artesunate. Mutations conferring mefloquine resistance were observed in Pfmdr1 at 56 57 positions N86Y, Y184F, and N1042D. Additionally, mutations associated with S/P resistance, 58 particularly in Pfdhfr and Pfdhps, were prevalent. Notably, a double mutation of Pfdhfr at positions 59R and 108N was highly prevalent (>99%), and multiple mutations were observed in 59 Pfdhps, notably 540E and 581G. These mutations were indicative of a strong selection pressure 60 imposed by the widespread use of these antimalarial drugs (Myo Thura Zaw et al., 2020). 61

Analysis of PfKelch13 mutations revealed the presence of mutations at positions P574L, Y493H, 62 and R539T, all confirmed by the WHO to confer resistance to artemisinin (Table 3). These 63 findings suggest the emergence of baseline resistance markers even in the absence of drug 64 pressure, highlighting the adaptive nature of *P. falciparum* to changing drug regimens (Pholwat 65 et al., 2017). Chloroquine ceased being used for *P. falciparum* due to high-level resistance, but 66 67 it remained first-line for *P. vivax.* While the K to T mutation at position 76 of *pfcrt* is thought to be pivotal in resistance, the 72-76 CVIET combination, indicative of Indonesian lineage, and 68 69 mutations in 326/356 have been at saturation for at least 15 years, present in 86-98% of 70 samples. No mutations associated with atovaquone resistance were detected.

Artemisinin resistance in *P. falciparum* has presented a significant challenge to malaria control efforts in the GMS. Monitoring mutations in the PfKelch13 gene, some strongly associated with artemisinin resistance, has aided national malaria programs in adjusting first-line therapies and increasing control efforts to inhibit transmission (Ménard et al., 2016). With PfKelch13

prevalence increasing in East Africa, understanding the emergence and spread of PfKelch13
 mutations may assist in the prediction and interruption of drug failures there.

The study contributes to understanding artemisinin resistance dynamics by detecting the 77 78 P574L, Y493H, and R539T mutations in samples collected from Tak, Thailand, between 1998 and 2001. These mutations were previously reported in Thailand in 2009, highlighting the 79 persistence and spread of resistance alleles over time. The findings underscore the early 80 emergence of resistance in the GMS, consistent with WHO assessments (Ashley et al., 2014). 81 Comparisons with earlier and subsequent studies could provide insights into mutation trends 82 83 over a decade. The study also ties into related research, emphasizing the importance of 84 ongoing surveillance and intervention efforts to combat anti-malarial resistance. Tools such as TACs offer valuable insights into resistance dynamics, aiding in the development of targeted 85 interventions to address the evolving challenges posed by malaria. 86

87 The importance of continuous surveillance to monitor resistance profiles and inform malaria control strategies cannot be overstated. Even amid declining malaria case numbers, vigilance is 88 crucial to prevent outbreaks and safeguard elimination efforts. The presence of drug-resistant 89 strains, particularly those resistant to artemisinin, threatens to undermine the progress made in 90 malaria control. The adaptive nature of *P. falciparum*, demonstrated by the observed 91 mutations, highlights the need for adaptable and robust malaria management programs. As 92 resistance markers continue to evolve, the use of advanced molecular techniques, such as TACs, 93 becomes indispensable in providing timely and accurate data to guide public health 94 95 interventions.

This study of archived blood samples from Tak Province. Thailand, using TagMan Array Cards 96 has provided valuable insights into the prevalence and types of drug-resistant mutations in *P*. 97 falciparum and to our knowledge this is the oldest reported PfKelch13 mutations found in the 98 99 GMS. The identification of key mutations associated with resistance to chloroquine, mefloquine, sulfadoxine/pyrimethamine, and artemisinin underscores the complex and 100 evolving challenge of malaria control. These findings highlight the necessity for ongoing 101 surveillance and adaptive public health strategies to combat the persistent threat of drug-102 resistant malaria. Advanced molecular tools and comprehensive genetic analysis are crucial in 103 informing and guiding these efforts, ensuring that control measures are both timely and 104 105 effective. The fight against malaria requires constant vigilance, innovation, and a commitment to understanding the ever-changing landscape of antimalarial resistance. 106
