26 Abstract

Background: Childhood obesity is a major public health concern in Australia and the
multicultural population of South-West Sydney. This study examined the influence of
parents' country of birth (COB) on the association between family socio-economic status
(SES), assessed by area-level disadvantage and annual household income, and childhood
obesity.

Methods: The analysis of data from the cross-sectional Growing Healthy Kids in Southwest
 Sydney (GHK-SWS) baseline survey of 1,815 children aged 5-16 years living in South
 Western Sydney, Australia employed generalised linear multinomial mixed models, with
 results presented as odds ratio and 95% confidence intervals.

Results: This study found a significant relationship between SES measures and the risk of
overweight and obesity in the study population. The risks of childhood obesity are greatest in
lower socioeconomic groups (across both SES metrics) regardless of their parents' COB
status. However, the overweight results are inconsistent across SES metrics and COB status.
The risk of being overweight was lower for Australian-born parents living in disadvantaged
areas but higher for those reporting lower income; and higher for Overseas-born parents
living in disadvantaged areas but lower for those reporting low household income.

Conclusion: Parents' SES is a consistent predictor of childhood obesity, and this relationship is not modified by parents' COB. However, the likelihood of a child being overweight varied between the parents' SES measures and COB. Prioritisation of the target population for area-level preventive public health interventions to modify obesogenic factors is recommended for a) obese children living in most disadvantaged areas and moderate disadvantaged areas regardless of their parents' COB; b) overweight and obese children of moderate disadvantaged areas regardless of their parents' COB.

50 Introduction

Childhood obesity is a global public health issue, with significant health, economic and social
effects. The global prevalence of childhood obesity is high, with substantial adverse
immediate and long-term consequences¹. A quarter of Australian children are overweight or
obese, with no evidence of a decline in the prevalence².

55 The aetiology of childhood overweight and obesity is multifaceted, involving a complex

56 interaction between genetic, environmental, cultural, behavioural, and socio-economic

57 factors³. Globally, low socio-economic status (SES) is an important determinant of the

58 prevalence of childhood obesity⁴. The persistent relationship between low SES and increased

59 overweight and obesity prevalence has been reported in several studies focusing on

60 Australian youth^{5,6} as well as in children of other high-income countries⁷. Population data in

Australia shows that differences in SES are related to the individual's country of origin⁸,

62 which is of particular significance in Australia, where approximately a third of the population

63 is overseas-born or has overseas-born parents⁹.

There has been some progress in the investigation of obesogenic factors for children and other vulnerable populations, but studies are few and the results are inconsistent¹⁰. Parents' country of birth (COB) and migration status^{11,12}, mothers' perceptions of healthy body weight¹³, maternal body mass index (BMI)¹², and a range of SES indicators, including parents' educational level, household income, place of residence, lifestyle patterns and employment status^{14,15} are important contributing factors to childhood overweight and obesity.

While previous research^{8,16} has found that both SES and ethnicity are associated with
childhood obesity in Australian primary school children, less clear is the extent to which

73	parents' COB modifies the relationship between SES (measured by both area-level
74	disadvantage and individual household income) and childhood overweight or obesity.
75	The high rates of childhood overweight and obesity in Australia—with one-third of children
76	living in the South Western Sydney Local Health District (SWSLHD) region of New South
77	Wales (NSW) ¹⁷ —has profound implications for public health policy, specifically concerning
78	which groups of children should be prioritised for health interventions. The SWSLHD region
79	has a population of approximately one million, including the largest population of culturally
80	and linguistically diverse (CALD) communities in NSW, with 36% of residents born
81	overseas and about 49% of families speaking a language other than English at home ¹⁸ . Such
82	demographic characteristics make this region an ideal location for our study.
83	The objectives of this paper are twofold: a) to investigate the relationship between parents'
84	SES and childhood overweight and obesity in SWSLHD, and b) to determine whether this
85	relationship is modified by parents' COB.

95 Methodology

96 Ethics Approval & Formal Consent

97 This study was approved by the Human Research Ethics Committee of South Western Sydney 98 Local Health District (HE18/078). Informed verbal consent was obtained from all the study 99 participants (i.e., Parents or carers aged ≥18 years who could provide the maximum 100 information about the selected child) before the interviews. The data was collected from 101 October and November 2018. The data was accessed for research purposes from February 2021 102 and the authors had no access to information that could identify participants during or after 103 data collection.

104 Questionnaire and Study Sample

105 We analysed the baseline data from the GHK-SWS study to evaluate the study objectives. The GHK-SWS baseline study—a cross-sectional population-based survey of parents or 106 carers of children aged 5-16 years in southwestern Sydney, NSW, Australia-was approved 107 108 by the Southwest Sydney Local Health District Human Research Ethics Committee (HE18/078) and conducted in 2018, with a follow-up study planned to be conducted in 2027. 109 The main paper from the GHK-SWS study presents a detailed description of the study design 110 and methodology¹⁹. In brief, the baseline questionnaire was developed using validated 111 questions from the 2018 NSW Child Population Health Survey²⁰, the NSW Schools Physical 112 Activity and Nutrition Survey²¹ and the Make Healthy Normal campaign evaluation²². Survey 113 domains included: demographics, health status, parental perception of height and weight, 114 dietary consumption (including fruit and vegetables and discretionary foods), nutrition-115 related behaviours, physical activity participation and sedentary activity, as well as several 116 knowledge and attitudes questions. The questionnaire was translated into Arabic, 117 Vietnamese, and Cantonese/Mandarin (simplified Chinese) as these are the major language 118

groups in our study area. GHK-SWS study data was collected using a computer-assisted
telephone interview (CATI) system.

The target population included all households with children aged 5-16 years within the study area and the sample frame consisted of residents' landline and mobile telephone numbers.
The primary carer (mother or father or grandparents) who could provide maximum information about the selected child was interviewed from each randomly selected household.
Following the contact, interviewers collected information on the number of eligible children living in the household and their gender and ages. If the household had more than one eligible children using the CATI

128 system's random number generator.

129 Measures

- 130 Outcome measure
- 131 The main outcome measure was the child's BMI. BMI was categorised using the age- and
- sex-specific International Obesity Task Force (IOTF) definitions²³: thin/underweight
- 133 (BMI<18 kg/m²), healthy weight (18 kg/m² \leq BMI<25 kg/m²), overweight (25 \leq BMI<30
- 134 kg/m²) and obese (BMI \geq 30 kg/m²). To determine BMI, the respondent was asked two
- 135 questions: 1. How tall is <CHILDNAME> without shoes? (in centimetres). 2. How much
- 136 does <CHILDNAME> weigh without clothes or shoes? (in kilograms). As the aim of this
- 137 paper was on childhood overweight and obesity, children with BMI $\leq 18 \text{ kg/m}^2$ were excluded
- 138 from the analysis (n=224).
- 139 Predictors of interest

140 The study's main predictor of interest was SES, which was assessed by two measures: area-

141 level SES and household income of participants. Area-level SES was calculated from the

2016 Index of Relative Socio-Economic Disadvantage (IRSED)²⁴ at the postcode level. The 142 IRSED was created by the Australian Bureau of Statistics to compare social and economic 143 disadvantage across geographic areas in Australia. The index is derived from Census 144 variables such as income, educational attainment, unemployment, and people working in 145 unskilled occupations. The IRSED was categorised into tertiles (Tertile 1: most 146 disadvantaged/low SES; Tertile 2: middle disadvantaged/middle SES; and Tertile 3: least 147 148 disadvantaged/high SES). The annual household income (before tax) of the respondents was grouped into four categories: \$0-\$51,999, \$52,000-\$77,999, \$78,000-\$103,999 and \$104,000 149 150 or more.

151 Effect Modifier

The other variable of interest was the parent's COB (as an effect modifier), which was grouped into Australian-born and overseas-born. To determine COB, the respondent was asked – "Can you tell me in which country <CHILDNAME>s mother/father/you was/were born"? As we only focus on parents (mothers and fathers) as the main carer for the children, other care relationships (e.g., grandparents or relatives) were excluded from the analysis (n=51). In this paper, parent refers to mothers (73.5%) and fathers (21.5%) and only their responses to survey questions were included in the analysis.

Socio-demographic variables reported in the survey included both the child's (age and gender) and parent's demographic characteristics (educational attainment, annual household income, and rurality of residence using the Accessibility/Remoteness Index of Australia Plus (ARIA+) index. The rurality of residence quantifies remoteness in terms of the travelling distance to different-sized population-adjusted service centres²⁵. The ARIA+ scores are classified into five groups: major cities, inner regional, outer regional, remote, and very remote.

Additionally, due to the known relationship between healthy lifestyle behaviours, childhood 166 BMI and area-level SES^{5,26}, three health behaviour factors were explored as potential 167 mediators: physical activity (PA) levels, sedentary screen time behaviour (SB) and 168 consumption of sugar-sweetened beverages (SSB). For PA, children were categorised 169 according to whether they met the current Australian PA guidelines²⁷ (yes, no) and were 170 asked the following question: "Over the past 7 days, on how many days was 171 172 <CHILDNAME> engaged in moderate to vigorous physical activity for at least 60 minutes each day (this can be accumulated over the entire day, for example in bouts of 10 minutes)?" 173 174 For SB, the current Australian guidelines recommend that children aged 5-17 years limit sedentary recreational screen time (such as watching TV, iPad, DVDs or on a mobile phone) 175 to two hours per day²⁷. SB was assessed by asking participants: "In a typical week (Monday 176 to Sunday), how many hours in total does <CHILDNAME> spend watching TV/iPad/DVDs, 177 using the computer/iPad/mobile phone for fun or playing video games?" and categorised into 178 <2 hours of screening time per day and >2 hours of screening per day. SSB consumption was 179 assessed by asking participants" How many cups of soft drink/cordial/sport drink/energy 180 drink, does their child usually drink in a day? Total consumption of SSB per day was 181 categorised into no cups, ≤ 1 cup, and >1 cup per day. The current Australian Dietary 182 Guidelines discourage the consumption of any SSBs in children due to the numerous 183 detrimental health effects²⁸. 184

185 Data analysis

A directed acyclic graph (DAG) was used to identify potential confounders, mediators, and
effect modifiers in the relationship between SES and children's overweight and obesity
(Figure 1). Following a comprehensive descriptive analysis, the R package "mma" was used
to conduct multiple mediation analysis²⁹. Multiple mediation analysis examined the presence
of the potential mediator factors: meeting PA, SB and SSB consumption guidelines. The

191	algorithms for the estimation of indirect effects were repeated 50 times with 500 times of
192	bootstrap resampling. These three health behaviours were not significant mediators for
193	children's overweight and obesity and were included as confounders in the final model.
194	Proc GLIMMIX procedure in SAS v9.4 was then used to conduct generalised linear
195	multinomial mixed models ²⁹ . This included random intercepts, which accounted for Local
196	Government Area (LGA) clustering effects, to determine associations between area-level
197	SES and Children's overweight and obesity. Children's age, gender, parent's relationship to
198	child (as mother or father), parent's educational attainment, annual household income, and
199	rurality of residence were included as confounders in the final model. Effect modification by
200	the main carer's (mother or father) COB was tested and was statistically significant
201	(p<0.0001).
202	Results from the multinomial multilevel regression model are presented as odds ratio (ORs)
203	and associated 95% confidence intervals (95%CIs). Survey weighting was used in all
204	analyses to ensure the survey sample was representative of all children living in SWSLHD.

218 **Results**

219	The socio-demographic cha	racteristics of participants and	re presented in Table	1. In total, the

220 GHK-SWS study collected data from 1,815 children. After exclusion of thin (underweight)

children (n=224) and other non-parents (n=51), the study findings are from the analysis of

1,535 children. Overall, 57% of children were within the healthy weight range (n=878), 23%

were overweight (n=367), and 20% were obese (n=290). About half of the participants were

boys (51%, n=790) and the mean age was 10.8 years (SD=4.5 years). The majority lived in

major cities (92%), with more than half of the participants (57%) living in more

disadvantaged areas and about one-third (34%) reporting an annual household income of less

than \$52,000. Most participating parents were mothers (74%), about half of whom were born

in Australia (51%), 35% have completed a university degree, 32% with a Technical and

Further Education (TAFE) diploma, and 33% with ≤ 12 years of school education.

232 TAFE: Technical and Further Education

233

234 Socio-demographic factors and BMI

In an adjusted model, using healthy weight as the reference, the socio-demographic factors

associated with higher odds of being overweight in children were: girls, aged 5-11 years,

parents born in Australia, parents who had only completed year 12 or less of education,

families with a reported annual household income less than \$77,999, living in a major city

and a moderate disadvantaged area (Table 2). Children were more likely to be obese if they

- 240 were: boys, aged 5-11 years, their fathers were the main carers, parents were born overseas,
- parents who had not completed a university degree, from families with a reported annual

- household income of less than \$52,000, living in inner regional areas, and from the most
- 243 disadvantaged areas. (Table 2).

249 SES= Socio Economic Status

250

251 Health Behaviours and BMI

In the same adjusted model (Table 2), children are more likely to be overweight when PA and

253 SSB guidelines are not met. Similar patterns were observed for children with higher odds of

being obese except for meeting PA guidelines: children who meet PA guidelines are more

likely to be obese (OR=1.09, 95 % CI=1.04-1.12) compared to all other children.

256 SES and BMI by Parents' COB

Figure 2 shows the associations between area-level SES, annual gross household income and

child overweight and obesity by parents' COB after adjusting for confounders.

259

260

261 262

263

269

270

271

272 Overweight and obesity in children with parents born in Australia

If parents were born in Australia, the odds of their child being overweight were highest for 273 274 families living in moderate disadvantaged areas (OR=1.36, 95% CI=1.27-1.46) but lowest for families living in the most disadvantaged areas (OR=0.78, 95% CI=0.74-0.83), compared to 275 those living in the least disadvantaged areas. Compared to an annual household income of 276 \$104,000 or more, an annual household income below \$77,999 was associated with a higher 277 risk for overweight (\$0-\$51,999: OR=1.88, 95% CI=1.78-2.00; \$52,000-\$77,999: OR=1.77, 278 95% CI=1.67-1.88), while an annual household income of \$78,000-\$103,999 was associated 279 280 with a lower risk (OR=0.78, 95% CI=0.73-0.83).

281 The risk of a child being obese was higher among participants living in the most and

moderately disadvantaged areas (most disadvantaged areas: OR=1.83, 95% CI=1.70-1.97;

moderate disadvantaged areas: OR=2.38, 95% CI=2.19-2.58) than living in the least

disadvantaged areas. The odds of being obese were also higher for all three annual household

income categories compared to the reference category of >\$104,000: (\$0-\$51,999: OR=3.28,

286 95% CI=3.06-3.52; \$52,000-\$77,999: OR=1.53, 95% CI=1.41-1.66; \$78,000-\$103,999

287 OR=1.60, 95% CI=1.49-1.72).

288 Overweight and obesity in children with parents born overseas

About parents born overseas, the odds of their children being overweight were higher for

families living in the most disadvantaged areas (OR=1.19, 95% CI=1.10-1.29), and moderate

disadvantaged areas (OR=1.42, 95% CI=1.29-1.57). The odds of children being overweight

 above \$104,000 or more (\$0-\$51,999: OR=0.81, 95% CI=0.76-0.87; \$52,000-\$77,999: OR=0.62, 95% CI=0.58-0.67). However, the odds of children being overweight were hig among families with a household annual income of \$78,000-\$103,999 (OR=1.23, 95% CI=1.14-1.32). As area-level SES increased, the odds of these children being obese followed a clearly increasing trend from least disadvantaged to most disadvantaged (moderate disadvantage areas: OR=1.22, 95% CI=1.11-1.34; most disadvantaged areas: OR=1.57, 95% CI=1.45- 1.70).). The odds of children being obese were higher among families with a reported annual household income of \$0-\$51,999 (OR=1.12, 95% CI=1.05-1.20), though to a much lesse extent than children whose parents were born in Australia. However, the odds of children being obese were lower among participants whose annual household income was between 		
 OR=0.62, 95% CI=0.58-0.67). However, the odds of children being overweight were hig among families with a household annual income of \$78,000-\$103,999 (OR=1.23, 95% CI=1.14-1.32). As area-level SES increased, the odds of these children being obese followed a clearly increasing trend from least disadvantaged to most disadvantaged (moderate disadvantage areas: OR=1.22, 95% CI=1.11-1.34; most disadvantaged areas: OR=1.57, 95% CI=1.45- 1.70).). The odds of children being obese were higher among families with a reported annual household income of \$0-\$51,999 (OR=1.12, 95% CI=1.05-1.20), though to a much lesse extent than children whose parents were born in Australia. However, the odds of children being obese were lower among participants whose annual household income was betwee \$52,000 and \$103,999 (\$52,000-\$77,999: OR=0.75, 95% CI=0.70-0.80; \$78,000-\$103,9 OR=0.51, 95% CI=0.47-0.56). 	292	were lower among families reporting an annual household income below \$77,999 than those

317 **Discussion**

This study found a significant relationship between SES measures (assessed by area-level 318 disadvantage and annual household income) and the risk of overweight and obesity among 319 children aged 5-16 years living in Southwest Sydney. The obesity results are consistent 320 across SES metrics and COB groups. A higher risk for childhood obesity was found for 321 children in low SES households regardless of whether SES status was measured by 322 household income or area of residence and this relationship held whether the responding 323 324 parent was born in Australia or outside Australia. Childhood obesity risk was three-fold higher for Australian-born parents with the lowest household income level. 325 326 The overweight results, however, are inconsistent across SES metrics and COB groups. Children of Australian-born parents had a lower risk of being overweight if they lived in low-327 SES areas, but children of overseas-born parents had a higher risk of being overweight if they 328 lived in low-SES areas. When SES was measured by annual household income, the opposite 329 was found. Children of Australian-born parents with low annual household incomes had a 330 higher risk of being overweight whereas children of overseas-born parents with low annual 331 household incomes had a lower risk of being overweight. 332 The increased risk of obesity in children of low SES groups across both Australian and 333 334 overseas-born parents in our study accords with the recent World Health Organization (WHO) report on ending childhood obesity³⁰. The existing evidence from WHO and recent 335

evidence from Australia demonstrates that the risks of childhood obesity are highest in lower

SES groups living in high-income countries^{31,32}. Indeed, in high-income countries, children 337 from low SES population groups such as immigrants, indigenous, and culturally and 338 linguistically diverse groups, are at a particularly high risk of developing obesity³⁰. 339 While many studies have examined the contribution of SES to differences in obesity by 340 ethnic group, very few studies have considered migration status as a factor³³. The limited 341 evidence from studies conducted in Europe³⁴, USA³⁵, Australia³⁶ and Germany³⁷ suggests 342 that weight increases substantially among migrant children over a post-migration period of 10 343 to 15 years and social and economic disadvantage of migrants is linked to an increased risk of 344 childhood obesity an association our study findings confirm. 345 In this study, the influence of SES as measured by both area and household income metrics 346 on childhood overweight and obesity was inconsistent across the two SES measures. SES 347 348 measured by household income and area-level disadvantage provide different contextual information. Further, the risk of childhood overweight and SES is also influenced by the type 349 350 of SES measure used in the analysis. For example, children of immigrants with low SES were at higher risk of being overweight when parental education was used as a proxy for SES³⁷ but 351 not when employment was used as an indicator of SES³⁸. Area-level SES also reflects other 352 area-level characteristics such as access to healthy foods and facilities for physical activity, 353 employment opportunities, and crime levels. Therefore, while household income is an 354 important SES metric, area-level SES may be a more useful measure when policy decisions 355 must be made to allocate resources or to implement population-level programs. The results 356 from our study and the literature indicate the need for further detailed studies to understand 357 the complexity and variation of childhood overweight and obesity in subgroups of the 358 population. 359

While household income is a known predictor of childhood obesity, this association was 360 significantly modified by parents' country of birth. A systematic review of socioeconomic 361 inequalities in childhood obesity in the United Kingdom, for example, found that while 362 household income can reliably be ascribed as a determinant of childhood obesity, such 363 findings were not consistent across all studies³⁹. Our study also confirms that low household 364 income is a reliable predictor of childhood obesity, regardless of children's COB status. Still, 365 366 when it comes to the question of being overweight, parents' COB is a modifying factor. Future studies would benefit from the inclusion of both area- and individual-level SES 367 368 metrics to explore their value in predicting childhood overweight and obesity. Childhood overweight and obesity arise from exposure of the child to an obesogenic 369 environment and insufficient responses to that environment. Such responses vary from person 370 to person for reasons that may be social, cultural, economic, environmental, or behavioural, 371 as discussed below. 372 373 There are plausible explanations for the increased risk of childhood overweight and/or obesity in the children of overseas-born parents living in disadvantaged neighbourhoods. 374 Residents of disadvantaged areas are more likely to be living with low wages, unemployment 375 or, uncertain employment, particularly if they are recent migrants, females, single parents 376 with dependent children, or speak a language other than English at home^{40,41}. Subsequent 377 378 generations of migrants, even those with higher income levels, are also more likely to experience marginalisation and reduced opportunity⁴², attain lower educational levels, and 379 lack the resources to own property⁴³. Moreover, while migrants may arrive in their new 380 country with certain health advantages, they are more likely to experience social isolation or 381

marginalisation, stress, and weight gain 10-15 years after migration 33 .

Besides the socioeconomic disadvantage of migrants, their exposure to obesogenic
environmental factors in host countries may also influence the higher prevalence of
overweight/obesity among their children^{44,45}. This phenomenon has been linked to the
challenges of acculturation, including lifestyle changes in the host country, lower levels of
physical activity, increased sedentary lifestyle^{18,34} and the adoption of unhealthy diets⁴⁵⁻⁴⁷.

388

389 Strengths and Limitations

BMI based on self-reported height and weight may cause moderate measurement bias. 390 However, evidence from a previous study suggests that correlations between self-reported 391 height, weight and BMI values and objectively measured values remained high and hence 392 support the use of self-reported values⁴⁸. While the study provides comprehensive 393 information based on sufficient sample size, representative population data and a standardised 394 questionnaire, a potential limitation is the assessment of the causal association between SES, 395 parents' country of birth and childhood overweight and obesity, because of its cross-sectional 396 design. While children's health behaviours, such as meeting physical activity, sedentary 397 behaviour, and sugar-sweetened beverage consumption guidelines, were adjusted in the final 398 model, future studies that include data on other obesogenic factors (such as the availability of 399 unhealthy food stores) would be an important area of research. 400

401 Conclusion

Parents' SES (measured by area level and household income) is a consistent predictor of childhood obesity, and this relationship is not modified by parents' COB. However, the likelihood of being overweight varied between the SES measures and parents' COB. It is recommended that the priority populations that should be targeted for preventive public health interventions to modify obesogenic factors include a) obese children living in most

SES-Paper1, FINAL V16 07.03.24

- 407 disadvantaged regardless of their parents' COB; b) overweight and obese children of
- 408 moderate disadvantaged areas regardless of their parents' COB.
- 409 Identifying the causes underlying the prevalence of overweight in children from different
- 410 COB backgrounds can provide further insight into the development of effective and relevant
- 411 policies and health promotion initiatives. As both area-level and household-level SES metrics
- 412 are associated with childhood obesity but inconsistently, therefore, future studies should
- 413 include both metrics when exploring associations with childhood obesity.

414 Acknowledgements

- 415 We firstly acknowledge the parents and carers of children living in the South West Sydney
- Local Health District who generously gave their time to complete the GHK-SWS Survey. We
- acknowledge the contribution of McNair Yellow Squares who were contracted by the
- 418 University of Sydney to undertake the survey. We also acknowledge the Growing Healthy
- 419 Kids Evaluation Advisory Group which contributed to the development of the survey and
- analysis of the data. Dr Phil Hughes of Engine Group provided the data weighting. We would
- 421 like to also thank Francis Fox for his language edits.

422 Financial Disclosure

- 423 We also acknowledge that the GHK study was funded by the New South Wales (NSW)
- 424 Ministry of Health, Australia. The funders had no role in study design, data collection and
- 425 analysis, decision to publish, or preparation of manuscript.

426 Declaration of Competing Interest

427 The authors have declared that no competing interests exist.

428 Authors' contributions

VK wrote the manuscript and was responsible for the design, drafting, interpretation of data,
reviewing and revisions of the manuscript. SC contributed to the design, conducted analysis
of data, wrote the results section, reviewing and revisions of the manuscript. BJ contributed
to the design, methodology, results and extensive reviewing, and revisions of the manuscript
and oversaw the data analysis and interpretation. JT, MC, MT, and MW contributed to the

- 434 revisions of the manuscript. All authors read and approved the final manuscript.
