ABSTRACT

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

1

2 Background

Genome-wide association studies (GWAS) have clustered candidate genes associated with
atrial fibrillation (AF) into biological pathways reflecting different pathophysiological mechanisms.
We investigated whether these pathways associate with distinct intermediate phenotypes and confer
differing risks of cardioembolic stroke.

7

8 Methods

9 Three distinct subsets of AF-associated genetic variants, each representing a different 10 mechanistic pathway, i.e., the cardiac muscle function and integrity pathway (15 variants), the cardiac 11 developmental pathway (25 variants), and the cardiac ion channels pathway (12 variants), were 12 identified from a previous AF GWAS. Using genetic epidemiological methods and large-scale 13 datasets such as UK Biobank, deCODE, and GIGASTROKE, we investigated the associations of 14 these pathways with AF-related cardiac intermediate phenotypes, which included ECG parameters (~16,500 ECGs), left atrial and ventricular size and function (~36,000 cardiac MRI scans), and 15 relevant plasma biomarkers (NT-proBNP, ~70,000 samples; high-sensitivity troponin I and T, 16 ~87,000 samples), as well as with subtypes of ischaemic stroke (~11,000 cases). 17 18 19 **Results** 20 Genetic variants representing distinct AF-related mechanistic pathways had significantly 21 different effects on several AF-related phenotypes. In particular, the muscle pathway was associated with a longer PR interval (P for heterogeneity between pathways $[P_{het}] = 1 \times 10^{-10}$), lower LA 22 emptying fraction ($P_{\text{het}} = 5 \times 10^{-5}$), and higher NT-proBNP ($P_{\text{het}} = 2 \times 10^{-3}$) per log-odds higher risk of 23 AF compared to the developmental and ion channel pathways. By contrast, the ion channel pathway 24 was associated with a lower risk of cardioembolic stroke ($P_{het} = 0.04$ in European, and 7×10^{-3} in 25 multi-ancestry populations) compared to the other pathways. 26 27

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

1 Conclusions

- 2 Genetic variants representing specific mechanistic pathways for AF are associated with distinct
- 3 intermediate cardiac phenotypes and a different risk of cardioembolic stroke. These findings provide a
- 4 better understanding of the aetiological heterogeneity underlying the development of AF and its
- 5 downstream impact on disease and may offer a route to more targeted treatment strategies.

INTRODUCTION

| 2 | Atrial fibrillation (AF) is the electrical end-point of radically different pathophysiological |
|----|---|
| 3 | pathways ^{1, 2} . Highlighting this complexity, linkage and family studies have associated AF with rare |
| 4 | variants in genes encoding not just ion channels ^{3, 4} , but transcription factors ⁵ , hormones ⁶ , and more |
| 5 | recently, cardiac structural proteins ⁷⁻¹¹ . In line with these findings, pathway and functional enrichment |
| 6 | analyses from a large genome-wide association study (GWAS) have suggested that many of the genes |
| 7 | annotated to AF-associated loci can be grouped into mechanistic pathways reflecting cardiac and |
| 8 | skeletal muscle function and integrity, developmental events, hormone signalling, angiogenesis and |
| 9 | myocardial ion channels ¹² . |
| 10 | In individuals with AF, a number of biomarkers and intermediate phenotypes have shown |
| 11 | associations with subsequent AF-related outcomes, such as stroke ¹³⁻¹⁵ . These findings may provide |
| 12 | opportunities for improving the management and risk stratification of patients with AF, as well as for |
| 13 | repurposing drugs that are already available for treating other diseases ¹² . However, there remains |
| 14 | uncertainty in our understanding of whether AF-associated mechanistic pathways are associated with |
| 15 | distinct cardiac phenotypes and differing risks of severe complications. |
| 16 | Using clusters of genetic variants representing different AF-associated mechanistic pathways ¹² , |
| 17 | we investigated associations between genetically-predicted AF pathways and AF-related intermediate |
| 18 | phenotypes, encompassing cardiac electrical, structural, and functional characteristics (ECG |
| 19 | parameters ¹⁶⁻¹⁸ , left atrial [LA] size and function ¹⁹⁻²¹ , left ventricular [LV] function ^{22, 23} , N-terminal |
| 20 | pro B-type natriuretic peptide [NT-proBNP] ^{24, 25} , and high-sensitivity cardiac troponins ²⁵⁻²⁷), and |
| 21 | examined their relevance to risk of stroke. |

METHODS

A summary of the study design is shown in **Supplementary Figure 1**.

3

2

4 Genetically-predicted mechanistic pathways associated with risk of AF

A total of 142 independent genome-wide significant variants ($P < 5 \times 10^{-8}$) were previously 5 6 identified in a large AF GWAS meta-analysis, referred to as the comprehensive 142-variant set hereafter, which captures broader genetic predisposition to AF¹². In the same study, these variants 7 were annotated to functional genes using a stringent multi-step process¹² in the following order of 8 9 priority: whether they were protein-altering, or in high linkage disequilibrium with protein-altering 10 variants; had expression levels that were associated and co-localised with AF-associated loci across 11 all tissue using Genotype-Tissue Expression (GTEx) consortium data; were identified by DEPICT 12 (Data-driven Expression Prioritized Integration for Complex Traits); or were the nearest gene to index variant in a locus. A further step grouped functional candidate genes (whenever possible) into 13 14 mechanistic pathways in which they were likely to be involved (e.g. muscle, developmental, ion channel)¹². Further details on the locus to gene and pathway annotation processes used in the GWAS¹² 15 16 are found in the Supplementary Methods. In the present study, we used independent genetic variants that had been annotated to three 17

distinct AF-related mechanistic pathways. The 'muscle pathway' comprised variants annotated to 18 19 genes involved in cardiac and skeletal muscle function and integrity (15 genetic variants, annotated to 20 14 distinct genes e.g. MYH6, PKP2, TTN). The 'developmental pathway' comprised variants 21 annotated to genes involved in cardiac developmental events (25 genetic variants, annotated to 12 22 distinct genes e.g. GATA4, NKX2-5, PITX2, TBX5). The 'ion channel pathway' comprised variants 23 annotated to genes involved in cardiac ion channels (12 genetic variants, annotated to 8 distinct genes 24 e.g. HCN4, KCNH2, KCNJ5, SCN5A). Of the comprehensive 142-variant set, 52 variants were 25 annotated to the genes likely to be involved in one of these three discretely defined non-overlapping 26 pathways.

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | The AF GWAS meta-analysis ¹² also identified variants annotated to genes likely to be involved |
|----|---|
| 2 | in calcium handling (4 variants), angiogenesis (1 variant) and hormone signalling (4 variants). These |
| 3 | potential pathways were not included in the present study as they were relatively non-specific and |
| 4 | comprised multiple heterogeneous biological pathways. For example, the hormone signalling pathway |
| 5 | identified genes associated with oestrogen receptors, thyroid receptors and insulin-like growth factor |
| 6 | receptors. Further details are provided in Supplementary Tables 1 - 4 . |
| 7 | |
| 8 | Study populations and outcome definitions |
| 9 | Details of the datasets used in this study are listed in Supplementary Table 5 . |
| 10 | |
| 11 | Atrial fibrillation |
| 12 | Genetic associations with AF were generated directly in UK Biobank ^{28, 29} in 339,189 unrelated |
| 13 | white British participants whose genetic samples passed bioinformatic quality control using logistic |
| 14 | regression with adjustments for sex, genotype array, and 7 principal components of population |
| 15 | structure. We identified 30,631 cases of AF or flutter, defined using electronic healthcare records with |
| 16 | details of definitions in Supplementary Table 6. Further details of phenotype codes utilised to define |
| 17 | co-morbidities are listed in Supplementary Table 7 . |
| 18 | |
| 19 | ECG parameters |
| 20 | As with AF, genetic associations with ECG parameters were generated directly in UK Biobank |
| 21 | using logistic regression with adjustments for sex, genotype array, and 7 principal components of |
| 22 | population structure. Resting 12-lead ECGs and automated measurements (using Cardiosoft v6 |
| 23 | program, GE) were available in 16,508 participants, and analyses of these data were conducted after |
| 24 | excluding individuals with AF on ECG, or AF identified as described above. |
| 25 | |

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

1 Cardiac MRI parameters

| 2 | Genetic associations with cardiac MRI imaging data including LA structure and function ³⁰ |
|----|--|
| 3 | (35,658 individuals of European ancestry) and LV structure and function ³¹ (36,041 individuals of |
| 4 | European ancestry), both regardless of history of AF, were based on existing summary data derived |
| 5 | from UK Biobank. The UK Biobank cardiac MRI protocol has been reported elsewhere ³² . In brief, LA |
| 6 | parameters were derived from automated processing algorithms; volumes were indexed to Du Bois |
| 7 | formula calculated body surface area and cardiac volume-time curves created to derive active and |
| 8 | passive LA emptying fractions ³⁰ . LV parameters were provided by UK Biobank, corrected for known |
| 9 | bias from the automated algorithm and indexed to Mosteller formula calculated body surface area ³¹ . |
| 10 | |
| 11 | NT-proBNP |
| 12 | Genetic associations with NT-proBNP were based on summary data including 33,043 |
| 13 | individuals from the UK Biobank Pharma Proteomics Project (UKB-PPP) ³³ and 35,559 Icelandic |
| 14 | individuals from the deCODE + Icelandic cancer project ³⁴ . These associations were further validated |
| 15 | in summary data including 3,301 healthy blood donors from the INTERVAL study ^{35, 36} and a GWAS |
| 16 | of 3,394 individuals with cardiovascular risk factors from the IMPROVE study ^{37, 38} . Assays for NT- |
| 17 | proBNP included Olink (UKB-PPP, IMPROVE) and SomaScan (deCODE + ICP, INTERVAL). |
| 18 | |
| 19 | High-sensitivity troponin I and T (hsTnI, hsTnT) |
| 20 | Genetic associations with hsTnI were based on summary data including 48,115 individuals |
| 21 | from the Trøndelag Health Study (HUNT) and Generation Scotland Family Health Study (GS:FHS) ³⁹ |
| 22 | and in 14,336 individuals of diverse ancestry (89% European, 11% African) across a number of |
| 23 | cohorts (including ARIC) but excluding individuals with baseline coronary heart disease and heart |
| 24 | failure as described by Yang et al ⁴⁰ . Genetic associations with hsTnT were based on summary data |
| 25 | including 24,617 individuals (76% European, 15% African, 7% Hispanic, 3% Asian) across a number |
| • | |

- 26 of cohorts (including ARIC, CHS, MESA) but excluding individuals with baseline coronary disease
- and heart failure⁴⁰.

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

1 2 Ischaemic stroke 3 Genetic associations with stroke outcomes were based on summary data from the GIGASTROKE GWAS meta-analysis⁴¹. Contributing studies defined the aetiology of stroke as per the TOAST (Trial 4 5 of Org in 10172 Acute Stroke Treatment) classification system⁴². In the present study, we examined 6 associations with cardioembolic stroke (10,804 European ancestry; 12,790 multi-ancestry) as a 7 downstream consequence of AF, and small-vessel stroke as a negative control due to its different risk 8 factor profile (6,811 European; 13,620 multi-ancestry). 9 10 **Statistical analysis** 11 Primary analyses 12 Ratio estimates for each individual variant were determined by dividing the gene-outcome 13 association (for each outcome of interest as described above) by the association with AF (taken from the published GWAS for AF¹² after exclusion of UK Biobank participants to reduce the potential for 14 15 bias). For each specific pathway, the individual variant ratio estimates were then combined using fixed-effects (assuming a single common effect) inverse variance weighted methods, with resulting 16 17 estimates corresponding to a unit increase in log-odds risk of AF (approximately a 2.7-fold higher 18 risk). 19 Heterogeneity between estimates from different pathways was assessed using Cochran's Q statistic and Wald tests to examine pair-wise differences between individual pathways. Nominal 20 21 significance was defined as a *P*-value <0.05, with more robust statistical significance defined as a *P*-22 value <0.01 to account for within-study multiple testing. 23 24 Sensitivity analyses 25 We conducted sensitivity analyses to assess the robustness of the results to underlying 26 methodological assumptions (based on a Mendelian randomisation [MR] instrumental variable 27 framework) including: inverse variance weighted random effects (allowing for heterogeneity between

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | instrumental variables); weighted median (in which up to 50% of the information is permitted to be |
|----|--|
| 2 | from invalid instrumental variables); weighted mode (which allows the majority of information to be |
| 3 | invalid provided the most common MR effect estimate is a consistent estimate of the true MR effect); |
| 4 | and MR-Egger (in which all genetic variants are permitted to be invalid instrumental variables, |
| 5 | provided that the pleiotropic and risk factor effects of the variants are independently distributed) ^{43, 44} . |
| 6 | MR estimates from each pathway were also estimated after exclusion of outlier variants identified |
| 7 | using the MR-PRESSO outlier detection method ⁴⁵ . 'Leave-one-out' analyses were performed to test |
| 8 | whether the effects of the pathways on cardioembolic stroke were sensitive to individual variants. |
| 9 | Additional post-hoc analyses were also undertaken to estimate the direct effects of the pathways on |
| 10 | outcomes showing heterogeneity between pathways (i.e. cardioembolic stroke), independent of their |
| 11 | associations with ECG parameters, LA parameters, and markers of LV dysfunction. To further |
| 12 | confirm that the scores were unrelated to conventional risk factors, within UK Biobank, participant- |
| 13 | level weighted AF risk scores were calculated for each of the pathways and the characteristics of the |
| 14 | top and bottom quintiles of score compared. |
| 15 | All analyses were performed using SAS (v 9.4, SAS Institute) and R (v 4.3.1, The R |
| 16 | Foundation for Statistical Computing). |
| 17 | |
| 18 | Standard protocol approvals, registrations, and patient consents |
| 19 | UK Biobank data were used from the UK Biobank Resource under Application Number 14568. |
| 20 | All procedures and data collection in UK Biobank were approved by the UK Biobank Research Ethics |
| 21 | Committee (reference number 11/NW/0274) with participants providing full written informed consent |
| 22 | for participation and subsequent use of their data for approved applications. Publicly available non- |
| 23 | identifiable summary statistics were used in this study for which the multiple contributory studies to |
| 24 | the various datasets had their own consent procedures. |
| | |

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | RESULTS |
|----------|--|
| 2 3 | Comparable risks of AF unrelated to demographics or co-morbidities across mechanistic pathways of genetic predisposition to AF |
| 4 | The estimated associations of AF of the three discrete pathways ('muscle'; 15 genetic variants, |
| 5 | 'developmental'; 25 variants, and 'ion channel'; 12 variants) are based on the individual genetic |
| 6 | variants' associations in the AF GWAS meta-analysis (excluding UK Biobank) ¹² . As a validation |
| 7 | step, we estimated the effects of these pathways on AF in the UK Biobank population. As anticipated, |
| 8 | the pathways conferred comparable risks of AF (<i>P</i> for heterogeneity 0.72; Supplementary Figure 2). |
| 9 | To investigate if the different pathways were associated with risk factors for AF, individual |
| 10 | weighted genetic AF risk scores for each of the pathways were calculated in UK Biobank. Participants |
| 11 | were split into quintiles of AF risk score and characteristics of the top versus bottom 20% compared |
| 12 | (Supplementary Table 8). As expected, other than risk of AF, no meaningful differences in |
| 13 | demographics or co-morbidities were noted. |
| 14 | |
| 15 16 | Differing associations with cardiac intermediate phenotypes across mechanistic pathways for same genetic predisposition to AF |
| 17 | Surface ECG parameters |
| 18 | In 16,508 participants from UK Biobank with no history of AF, the genetically-predicted AF |
| 19 | pathways were associated with different effects on P-wave duration, and PR interval (P for |
| 20 | heterogeneity 0.03, and 1×10^{-10} respectively; Figure 1). In particular, the developmental and ion |
| 21 | channel pathways were associated with a shorter P-wave duration, but the muscle pathway was not |
| 22 | (Figure 1). Conversely, the muscle pathway was associated with a <i>longer</i> PR interval (by 5.58 ms, |
| 23 | 95% CI: 2.59 to 8.58, $P = 3 \times 10^{-4}$ per log-odds higher genetically-predicted risk of AF), whilst the |
| 24 | ion channel pathway was associated with a shorter PR interval (by 8.64 ms, 95% CI: -11.53 to -5.75, |
| 25 | $P = 4 \times 10^{-9}$ per log-odds higher genetically-predicted risk of AF; Figure 1). This pattern remained the |
| 26 | same after adjusting the ECG PR interval for the P-wave duration, (<i>P</i> for heterogeneity 3×10^{-10} ; |
| 27 | Supplementary Figure 3). |

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | There were small but significant differences between the associations with QRS duration for |
|--|---|
| 2 | the three pathways (<i>P</i> for heterogeneity 2×10^{-5} ; Figure 1), but not with corrected QT interval (<i>P</i> for |
| 3 | heterogeneity 0.18; Figure 1). There were differences between the associations of the pathways with |
| 4 | heart rate (<i>P</i> for heterogeneity 0.01; Figure 1), with a log-odds higher genetically-predicted risk of |
| 5 | AF via the ion channel pathway being associated with a lower heart rate (-1.54 bpm 95% CI: -2.70 to |
| 6 | -0.39, $P = 9 \times 10^{-3}$), whereas other pathways showed no association. |
| 7 | By contrast, overall AF genetic susceptibility (i.e., as conferred by the 142-variant set) was not |
| 8 | associated with differences in PR interval duration ($P = 0.33$; Supplementary Figure 4) but was |
| 9 | associated with a shorter P-wave (-1.25 ms; 95% CI: -1.79 to -0.71; $P = 6 \times 10^{-6}$) and QRS duration (- |
| 10 | 0.95 ms; 95% CI: -1.37 to -0.53, $P = 1 \times 10^{-5}$) per unit log-odds higher risk of AF. |
| 11 | These findings indicate that mechanistic pathways of genetic predisposition to AF have |
| 12 | different associations with ECG parameters (most strikingly for the PR interval), which may not be |
| 13 | apparent when overall genetic AF susceptibility is considered. |

There were differences in the effects observedbetween different pathways for passive phase LA emptying fraction (<i>P</i> for heterogeneity 5 × 10 ⁻⁵). |
| 15 16 17 18 19 20 21 22 23 24 25 26 27 | Left atrial size and functionWe then investigated the association of the pathways with LA structure and function usingGWAS summary data from 35,658 UK Biobank participants who underwent a cardiac MRI scan ³⁰ .Whilst each AF pathway was similarly associated with larger maximum LA volumes (<i>P</i> forheterogeneity 0.33; Figure 2A), the magnitude of the associations with minimum LA volume differedacross the pathways (<i>P</i> for heterogeneity 0.02; Figure 2A). Specifically, the muscle pathway wasassociated with a larger minimum LA volume compared with the developmental ($P = 7 \times 10^{-3}$) andwith the ion channel pathway ($P = 0.04$). The 142-variant set for overall AF susceptibility wasassociated with larger maximal and minimum LA volumes (Supplementary Figure 5A).When assessing LA function, we used previously defined passive and active phase LAemptying fraction measurements from cardiac MRI ³⁰ . There were differences in the effects observedbetween different pathways for passive phase LA emptying fraction (<i>P</i> for heterogeneity 5 × 10 ⁻⁵).Specifically, a higher genetically-predicted risk of AF <i>via</i> the muscle pathway was associated with a |

| 1 | lower passive phase LA emptying fraction (-1.18%; 95% CI: -1.75 to -0.61, $P = 5 \times 10^{-5}$), but no |
|----|---|
| 2 | association was observed with the other pathways (Figure 2B). The comprehensive 142-variant set |
| 3 | for AF susceptibility was not associated with passive phase LA emptying fraction (Supplementary |
| 4 | Figure 5B). |
| 5 | By contrast, each of the three mechanistic pathways and the 142-variant set were associated |
| 6 | with a lower active phase LA emptying fraction (Figure 2B, Supplementary Figure 5B), and whilst |
| 7 | the effect of the muscle pathway was the most extreme (as observed for the passive phase of LA |
| 8 | emptying fraction), there was no significant difference between the pathways (P for heterogeneity |
| 9 | 0.06; Figure 2B). |
| 10 | In summary, different mechanistic pathways of genetic predisposition to AF had different |
| 11 | associations with LA structure and function. Amongst these, the muscle pathway was associated with |
| 12 | larger LA size and more impaired LA function compared with the other pathways. |
| 13 | |
| 14 | Left ventricular function |
| 15 | Left ventricular dysfunction and AF share a complex bi-directional relationship. To investigate |
| 16 | whether biologically-informed pathways underpinning AF risk were differentially linked to imaging |
| 17 | biomarkers of LV function, we examined their associations with LV ejection fraction (LVEF) using |
| 18 | GWAS summary data from 36,041 UK Biobank participants who underwent a cardiac MRI scan ³¹ . |
| 19 | None of the individual pathways were associated with LVEF, and there were no significant |
| 20 | differences between pathways (Supplementary Table 9). The muscle pathway was associated with a |
| 21 | 0.65 ml/m ² lower indexed LV stroke volume (95% CI: -1.18 to -0.12; $P = 0.02$), but associations did |
| 22 | not differ significantly between the pathways (<i>P</i> for heterogeneity 0.14; Supplementary Table 9). |
| 23 | The 142-variant set was associated with a 0.17% lower LV ejection fraction (95% CI: -0.23 to -0.004; |
| 24 | P = 0.04) and a 0.20 ml/m ² lower indexed LV stroke volume (95% CI: -0.35 to -0.04; $P = 0.01$). |
| 25 | |

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

1 NT-proBNP

| 2 | We also examined associations with NT-proBNP using summary statistics from a cohort of |
|----|--|
| 3 | 33,043 individuals from the UKB-PPP ³³ (mean age 59 years and similar to the whole UK Biobank |
| 4 | cohort in terms of co-morbidities) and a cohort of 35,559 Icelandic individuals from the deCODE + |
| 5 | Icelandic cancer projects ³⁴ (mean age 55 years with a variety of co-morbidities). |
| 6 | The biological pathways showed different associations with NT-proBNP (P for heterogeneity 2 |
| 7 | $\times 10^{-3}$ and 2×10^{-5} for UKB-PPP and deCODE + ICP respectively; Figure 3). In these two large |
| 8 | cohorts, only the muscle pathway was associated with higher levels of NT-proBNP (0.13 standard |
| 9 | deviation (SD) unit higher; 95% CI: 0.06 to 0.20, $P = 5 \times 10^{-4}$ in UKB-PPP and 0.24 SD unit higher; |
| 10 | 95% CI: 0.16 to 0.32, $P = 4 \times 10^{-9}$ in deCODE + ICP), with no associations noted for the other |
| 11 | pathways (Figure 3). |
| 12 | To assess the sensitivity of these findings to population characteristics, we examined the |
| 13 | associations in a population of 3,301 healthy blood donors from the INTERVAL study ³⁵ (mean age 43 |
| 14 | years) and in 3,394 older adults with risk factors for cardiovascular disease from the IMPROVE |
| 15 | study ³⁷ (mean age 65 years). Consistent with UKB-PPP and deCODE + ICP, only the muscle pathway |
| 16 | was associated with a higher level of NT-proBNP, with significant heterogeneity between pathways |
| 17 | seen in both cohorts ($P = 4 \times 10^{-3}$ and $P = 0.04$ respectively; Supplementary Figure 6). The 142- |
| 18 | variant set for overall risk of AF was also associated with higher levels of NT-proBNP, but only in the |
| 19 | UKB-PPP and deCODE + ICP cohorts (Supplementary Figure 7). |
| 20 | |

21 High sensitivity Troponins

To evaluate whether changes in LA function and biomarkers of LV dysfunction were linked to myocardial injury, we investigated associations with hsTnI (multi-ancestry population of 48,115 individuals³⁹ and in a separate multi-ancestry population of 14,336 individuals free from prevalent coronary heart disease or heart failure⁴⁰) and hsTnT (24,617 multi-ancestry individuals free from prevalent coronary heart disease or heart failure⁴⁰) using GWAS summary data.

| 1 | We found no differences between the biological pathways in terms of their associations with |
|----|--|
| 2 | hsTnI or hsTnT (P for heterogeneity 0.14 and 0.36 for the hsTnI cohorts, and 0.85 for the hsTnT |
| 3 | cohort; Supplementary Figure 8). |
| 4 | The 142-variant set was not associated with higher hsTnI levels in the general population but |
| 5 | was associated with a slightly higher level of both TnI and TnT in multi-ethnic populations free from |
| 6 | prevalent coronary heart disease or heart failure (Supplementary Figure 9). |
| 7 | Overall, these data provide further evidence that different mechanisms underlying the genetic |
| 8 | risk of AF are associated with distinct cardiac phenotypes and suggest that the muscle pathway is |
| 9 | associated with biomarkers of LV dysfunction, but not myocardial injury, in addition to left atrial |
| 10 | dysfunction. |
| 11 | |
| 12 | Genetic predisposition to AF conferred by mechanistic pathways is associated with different |
| 13 | risks of cardioembolic, but not small vessel ischaemic stroke |
| 14 | We next investigated whether different pathways of genetically-predicted risk for AF may be |
| 15 | associated with a different risk of cardioembolic stroke, for which AF is a significant risk factor, but |
| 16 | not with small-vessel stroke (as a negative control) due to its differing risk factor profile. We used |
| 17 | summary statistics from the GIGASTROKE meta-analysis employing the TOAST classification |
| 18 | system ⁴² to categorise acute stroke subtypes. |
| 19 | In analyses limited to individuals of European ancestry (comparable to the population in which |
| 20 | the AF GWAS was undertaken ¹²), the three pathways were differentially associated with risk of |
| 21 | cardioembolic stroke (P for heterogeneity 0.04; Figure 4). Specifically, the ion channel pathway was |
| 22 | associated with a lower risk of cardioembolic stroke, most profoundly when compared with the |
| 23 | developmental pathway ($P = 0.01$). In the larger multi-ancestry GIGASTROKE meta-analysis, we |
| 24 | were similarly able to replicate the differences in the risk of cardioembolic stroke across the different |
| 25 | pathways (<i>P</i> for heterogeneity 7×10^{-3}), again with a lower risk conferred by the ion channel pathway |
| 26 | (OR for cardioembolic stroke, 1.66; 95% CI 1.43, 1.93 per log odds higher genetically predicted risk |
| 27 | of AF), particularly when compared with the developmental pathway ($P = 1 \times 10^{-3}$; Figure 4). By |
| 28 | contrast, none of the individual pathways was associated with small-vessel ischaemic stroke, with no |

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | significant heterogeneity among the estimates (P for heterogeneity 0.20; Supplementary Figure 10). |
|----|--|
| 2 | Consistent with previous MR studies of AF and stroke ^{46,47} , the 142-variant set for overall AF |
| 3 | susceptibility was associated with a higher risk of cardioembolic stroke, but not with small-vessel |
| 4 | ischaemic stroke (Supplementary Figure 11). |
| 5 | Overall, these findings suggest that different mechanisms underlying the genetic risk of AF are |
| 6 | not only associated with distinct intermediate phenotypes but also with different risks of |
| 7 | cardioembolic stroke. |
| 8 | |
| 9 | Sensitivity Analyses |
| 10 | Investigations for pleiotropic effects within the pathways |
| 11 | Sensitivity analyses conducted for each phenotype did not suggest pleiotropy, and indicated |
| 12 | effect estimates were robust to methodological assumptions. Further details are available in the |
| 13 | Supplementary Results section and Supplementary Table 10. Funnel plots to visualise the effects |
| 14 | of each variant on risk of cardioembolic stroke within each AF score are shown in Supplementary |
| 15 | Figures 12 - 14 and 'leave-one-out' analyses suggested results were robust to the exclusion of |
| 16 | individual genetic variants (Supplementary Figures 15 - 17). |
| 17 | |
| 18 | Potential effects of pathway-associated intermediate phenotypes on risk of cardioembolic stroke |
| 19 | We performed analyses for cardioembolic stroke adjusted for the effects of the variants on the |
| 20 | intermediate phenotypes, grouped by ECG parameters, markers of LA size and function, and then NT- |
| 21 | proBNP and LV ejection fraction. Estimates were comparable before and after adjustment |
| 22 | (Supplementary Tables 11 - 13), suggesting that associations between the variants and intermediate |
| 23 | phenotypes examined in this study are unlikely to fully explain the differences in association with |
| 24 | cardioembolic stroke. |
| 25 | |

DISCUSSION

Our findings indicate that distinct biological pathways underlying the genetically-predicted risk of AF are differentially associated with atrial and ventricular phenotypes, and, importantly, with the risk of cardioembolic stroke. This study not only validates the heterogeneous nature of the disease processes predisposing to AF, but highlights the potential for improved risk stratification and more targeted therapeutic strategies.

7

8 Biological pathways for AF

9 A variety of biological pathways underpinning the development of AF have been identified using clinical, laboratory and animal methods^{1, 2}. Commensurate with early understanding of AF as a 10 11 primarily 'electrical' disease, initial linkage analyses identified ion-channel genes as potentially relevant in the pathogenesis of AF^{3, 48}. More recently, large GWAS have identified many common 12 genetic variants underlying AF susceptibility and have used an array of *in-silico* approaches to 13 suggest their relevance to distinct biological pathways¹². Within this framework however, combining 14 information across the genome without biological considerations could obscure important mechanistic 15 16 distinctions, prompting us to investigate the relevance of discrete biologically-informed genetic 17 pathways associated with AF risk.

18 Our findings suggest that different AF-related mechanisms have different effects on 19 biomarkers, intermediate phenotypes, and risk of cardioembolic stroke, which may partially explain 20 the heterogeneity seen in observational studies linking ECG ¹⁶⁻¹⁸, cardiac imaging parameters¹⁹⁻²², and 21 natriuretic peptides^{49, 50} with risk of AF.

22

23 Atrial and ventricular substrates

Changes in atrial and ventricular substrates in the context of AF are complex and have been well described^{1, 51}, with a number of intermediate phenotypes affecting both atria and ventricles being relevant to AF (e.g. P-wave duration or QT interval^{16, 17}, LA volume⁵² or emptying fraction⁵³, and LV dysfunction²²). We initially investigated whether genetic variation associated with risk of AF and

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

1 representing three distinct pathways (ion-channel, muscle structure and function, and developmental 2 pathways) had different effects on intermediate phenotypes in individuals in sinus rhythm. 3 Out of the surface ECG parameters, most strikingly, the muscle and the ion-channel pathways 4 had directionally opposite associations with the PR interval. Strong associations between the 5 pathways with P-wave duration were not seen in our study and thus the heterogeneity seen for 6 associations with the PR interval persisted even after adjusting for P-wave duration. This may suggest 7 that variations in AV node transit time rather than measures of atrial depolarisation reflect different 8 biological pathways to AF and related outcomes. However, ECG parameters in UK Biobank are based 9 on automated ECG recordings and measuring P-waves using automated ECG algorithms has considerable challenges given their low amplitude and variability across different ECG leads^{54, 55}, so it 10 is possible that the PR interval associations simply more accurately reflect atrial electrical parameters 11 12 or include atrial repolarisation which the P-wave duration may not. 13 Observational data have suggested that both short and long P-wave durations and PR intervals are associated with a higher risk of AF^{17, 18}, and Mendelian randomisation studies have suggested 14 15 shorter atrial ECG parameters are associated with a higher risk of AF, commensurate with the effects of the ion-channel pathway⁵⁶. Our findings are consistent with data linking an atrial cardiomyopathic 16 substrate to slower atrial conduction⁵⁷⁻⁵⁹, whereas shorter PR intervals may reflect shortening of atrial 17 action potential duration (as seen in those with AF⁶⁰) and more rapid conduction. Further investigation 18 19 would be needed to establish whether these insights also provide information on the mechanisms 20 underpinning AF development (e.g. re-entrant versus multiple wavelets, or trigger-dependent versus 21 substrate dependent). 22 Our study showed differing associations of the AF-associated biological pathways with NT-23 proBNP, with the muscle pathway being associated with higher plasma levels across all cohorts, 24 including in seemingly healthy, younger subjects. We also observed associations between the muscle and ion-channel pathways and QRS interval duration on ECG, and that the muscle pathway was 25 26 associated with a lower indexed LV stroke volume. The muscle pathway also had the strongest 27 associations with lower left atrial function, particularly in the passive emptying phase, which may

28 indicate associations with LV diastolic dysfunction more generally.

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | Associations between NT-proBNP and AF have been reported widely in the literature alongside |
|----|---|
| 2 | a consistently increased risk of stroke ^{24, 25} . Our previous work also indicated that people with "lone" |
| 3 | AF continue to show evidence of subtle ventricular dysfunction and impaired myocardial energetics |
| 4 | on cardiac magnetic resonance imaging/spectroscopy, despite normalisation of rhythm ~6 months |
| 5 | post-ablation, consistent with the presence of a subclinical cardiomyopathy underpinning AF ²² . |
| 6 | Our analyses did not support any consistent difference in the effect of AF-associated pathways |
| 7 | on hsTnI/T levels in a general population, or separately in a cohort of individuals free from coronary |
| 8 | artery disease or heart failure. In subjects with AF, hsTnI/T levels have been shown to be relevant to |
| 9 | risk-stratification for future cardiovascular outcomes ²⁵⁻²⁷ . Whilst the muscle pathway in particular was |
| 10 | associated with markers of LA and LV dysfunction, this does not necessarily reflect the presence of |
| 11 | myocardial injury and cell death. Other findings suggest that this relationship may be accounted for, at |
| 12 | least in part, by concomitant coronary disease ⁶¹ . |
| 13 | |
| | |

14 Different risks of stroke based on different pathways to AF

Our study suggests that genetic variants representing different pathways associated with risk of 15 AF can confer differing risks of cardioembolic stroke. There is evidence suggesting that structural or 16 electrical changes within the atria may lead to thromboembolism and AF independently^{52, 62-64}. 17 18 Furthermore, missense mutations in genes associated with changes in atrial structure confer an increased risk of both AF and stroke^{8, 9, 65}. This has given rise to the hypothesis that AF and stroke 19 may be the distinct endpoints of a cardiomyopathic substrate^{15, 66-69}. In our study, the same risk of AF 20 21 underpinned by different biological pathways was associated with differences in the risk of 22 cardioembolic stroke.

Whilst we demonstrated associations between the ion channel pathway and ECG parameters, as well as the muscle pathway and some of the known intermediate phenotypes for atrial and ventricular cardiomyopathy, the developmental pathway for AF was associated with a higher risk of stroke in the absence of an 'obvious' atrial phenotype as assessed by conventional biomarkers. Although the function of the specific variants included in the developmental pathway (*PITX2*, *NKX2-5*, *GATA 4* and *TBX5*) is only partially known⁴, these genes may impact cardiac development in early life, with

Gajendragadkar et al,; Genetic pathways for AF and risk of stroke

| 1 | evidence that missense mutations in TBX5 can lead to profound atrial transcriptional alteration and |
|----|--|
| 2 | AF ⁷⁰ . Investigation of more sophisticated biomarkers may yield more insights into understanding how |
| 3 | this pathway impacts AF and stroke risk. |
| 4 | Our study provides insights into disease aetiology that may allow better risk profiling of |
| 5 | patients and help inform treatment pathways. Further studies are needed to understand if individuals |
| 6 | with AF who have risk profile patterns associated with different biological mechanisms may derive |
| 7 | more benefit from specific interventions. |
| 8 | |
| 9 | Limitations |
| 10 | To define our biological pathways, we used the current largest GWAS for AF and its multi- |
| 11 | modal <i>in-silico</i> gene and pathway annotations, and selected variants meeting GWAS significance ¹² . |
| 12 | Pathway annotation is complex and based on existing knowledge of functions of genes and thus |
| 13 | limited by new scientific discovery. Whilst the associations observed with different intermediate |
| 14 | phenotypes validates the different pathways represented to some extent, we did not comprehensively |
| 15 | test distinct biological pathways as a whole, but rather specific variants within these pathways known |
| 16 | to be associated with AF. |
| 17 | The GWAS for AF used for genetic variant selection were conducted in participants with |
| 18 | European ancestry, and outcomes were also chiefly examined in studies of European ancestry, so |
| 19 | further studies would be needed to assess the generalisability of our results across more diverse |
| 20 | ethnicities. |
| 21 | |
| 22 | Conclusions |
| 23 | Genetic variants representing distinct biological pathways for AF susceptibility have differing |
| 24 | effects on intermediate cardiac electrical, structural and functional phenotypes, extending to the |
| 25 | ventricle, and risk of cardioembolic stroke. These findings provide a better understanding of the |
| 26 | aetiological heterogeneity driving the development of AF and may offer a route to genetically- |
| 27 | informed treatment strategies. |
