# **Help-seeking needs related to suicide prevention for individuals in contact with mental health services: A rapid scoping review**

Hwayeon Danielle Shin<sup>a,b</sup>, Jessica Kemp<sup>a,b</sup>, Samantha Groves<sup>c</sup>, Laura Bennett-Poynter<sup>c</sup>, Charlotte Pape<sup>a,b</sup>, Karen Lascelles<sup>c</sup>, Gillian Strudwick<sup>a,b</sup>

<sup>a</sup> *Campbell Family Mental Health Research Institute, Centre for Addiction and Mental Health, Toronto, Ontario, Canada*

<sup>b</sup> *Institute of Health Policy, Management, and Evaluation, University of Toronto, Toronto, Ontario, Canada*

<sup>c</sup> *Oxford Health NHS Foundation Trust, Oxford, United Kingdom*

## **Funding**

This work was supported by the Centre for Addiction and Mental Health (CAMH) and Oxford Health NHS Foundation Trust (OHFT).

## **Author Contributions**

GS conceptualized this review. JK developed the search strategy with a librarian. HDS, JK, SG, LBP, CP participated in screening titles and abstracts and assessing full texts against the inclusion criteria. HDS, JK, SG, LBP, CP participated in data extraction and analysis. HDS and JK developed tables and figures for data presentation. HDS wrote the first draft of the review report. All authors critically reviewed and provided feedback on the manuscript. HDS worked on manuscript revisions. KL and GS supervised all steps of this review.

## **Acknowledgements**

We would like to thank librarian, Reena Besa, who helped us build the search strategy.

## **Ethical Statements**

This is a scoping review on existing literature; therefore, it does not require ethical approval.

## **Conflicts of Interest**

There are no conflicts of interest to declare with this submission.

## Structured Abstract

**Introduction:** Prior mental health care utilization presents an important window of opportunity for providing suicide prevention interventions. To date, no reviews have consolidated the help-seeking needs of individuals in contact with mental health services. This warrants further attention given this group may have different needs for interventions compared to the general population who have not sought help previously.

**Aim:** The purpose of this rapid scoping review was to summarize the available literature on help-seeking needs related to suicide prevention among individuals in contact with mental health services from healthcare settings.

**Method:** Cochrane rapid review and Joanna Briggs Institute scoping review methodologies were adapted, and databases, including MEDLINE, Scopus, CINAHL, PsycInfo, and EMBASE, were searched.

**Results:** A total of 42 primary studies were included in analysis. Reported barriers and facilitators to help-seeking behaviors identified within studies were mapped onto the socio-ecological model. Barriers and facilitators identified included knowledge and attitudes toward healthcare utilization, family and peer support, interactions with healthcare professionals, provision of holistic care, and the creation of a supportive atmosphere and safe space to promote open discussions of suicide-related concerns.

**Discussion:** The findings of this review offer valuable insights into areas for improvement in addressing help-seeking needs for individuals who are in contact with health services related to suicide prevention.

**Implication for Research:** The findings serve as a foundation for shaping mental health initiatives informing approaches and care delivery tailored towards individuals who are in contact with health services. The reported barriers and facilitators offer insights to inform the development of mental health support tools to enhance care and considerations for evaluations.

## Accessible Summary

### What is known on the subject:

- When individuals contact healthcare services while experiencing suicidal thoughts or behaviors, it is an important opportunity to offer them help and interventions to prevent suicide; however, this does not necessarily mean that their needs are always met.
- Previous research has identified abundant evidence on help-seeking barriers and facilitators for mental health support; however, we do not have a consolidated understanding of the help-seeking needs, including unmet needs, for individuals in contact with mental health services, which may differ from individuals who have not sought care recently.

### What the paper adds to existing knowledge:

- This review consolidated the reasons why health service users might seek or avoid help when experiencing thoughts of suicide, organizing them as barriers and facilitators within the adapted socio-ecological model.

## What are the implications for research:

- The findings from the review can form the basis for shaping mental health initiatives related to approaches and care delivery.
- The identified barriers and facilitators can provide valuable insights for designing mental health support tools and considerations for evaluations.

## Background

Every year, around 700,000 people die by suicide globally (World Health Organization, 2014, 2021). Based on an analysis of the World Mental Health Surveys (conducted 2001-2007) involving 108,705 adults in developed countries, the estimated 12-month prevalence of suicidal thoughts, plans, and attempts was 2.0%, 0.6%, and 0.3% respectively (Borges *et al.*, 2010). A more recent meta-analysis of 66 studies including children and adolescents estimated the global 12-month prevalence of suicidal thoughts, plans and attempts to be 14.2%, 7.5% and 4.5% respectively (Lim *et al.*, 2019). In line with these findings, evidence continues to highlight the significant prevalence of suicide-related thoughts and behaviours among adults and youth worldwide (Lovero *et al.*, 2023; Van Meter *et al.*, 2022), emphasizing the need for effective suicide prevention and mental health support strategies.

Previous research has identified an abundance of evidence on risk factors for suicide and suicidal behaviors (Favril *et al.*, 2023). Previous self-harm or suicide attempts are the strongest risk factors for future suicide (Hawton *et al.*, 2015, 2020), with mental health conditions also contributing to risk (Favril *et al.*, 2022). A study reviewing 2,674 patients who died by suicide from eight healthcare systems found that 51.3% of individuals had at least one mental health diagnosis recorded in the year before their death. The diagnoses associated with highest risk of suicide were schizophrenia, bipolar, depressive, and anxiety disorders followed by attention deficit hyperactivity disorder (ADHD) (Yeh *et al.*, 2019). Among individuals with mental health conditions or a history of previous suicidal behaviors, demographic characteristics may increase or decrease risk of suicide including, but not limited to, gender (Marconi *et al.*, 2023; Miranda-Mendizabal *et al.*, 2019), age (Biswas *et al.*, 2020; Clements *et al.*, 2019; Hawton *et al.*, 2020; Murphy *et al.*, 2012), sexual orientation (Liu *et al.*, 2019), socio-economic status (Cairns *et al.*, 2017; Qian *et al.*, 2023), experiences of marginalization (Pollock *et al.*, 2018; Rudes & Fantuzzi, 2022), geographic location (Knipe *et al.*, 2022), neurodiversity and autism (Cassidy *et al.*, 2020), physical health (Qin *et al.*, 2022), and occupation (Windsor-Shellard & Gunnell, 2019).

Suicide is preventable through evidence-based interventions (Mann *et al.*, 2005; Nuij *et al.*, 2021; Zalsman *et al.*, 2016). Connecting individuals experiencing suicidal ideation and behaviors with appropriate mental health services is a critical aspect of suicide prevention and support efforts. Many individuals who die by suicide or attempt suicide are already in contact or have been in contact with mental health services (Stene-Larsen & Reneflot, 2019). A systematic review examining rates of contact with primary and mental health services prior to suicide found that among individuals who died by suicide, 57% had received mental health care in their lifetime, and 31% had received care in the year before death (Stene-Larsen & Reneflot, 2019). This finding is consistent with studies in other countries such as Wales (John *et al.*, 2020) and Sweden (Bergqvist *et al.*, 2022). The recency of healthcare utilization prior to suicide presents a key window of opportunity for individuals to be provided with suicide prevention interventions and support.

## Rationale and aim

Previous reviews have examined help-seeking behaviours regarding mental health among individuals who are at increased risk of suicidal behaviours. A systematic review examining help-seeking behaviors of adolescents for common mental health issues (including suicidal ideation) found stigma and unfavorable perceptions of mental health services were primary barriers to seeking help (Aguirre Velasco *et al.*, 2020). In contrast, prior positive experiences with health services and increased mental health awareness were help-seeking facilitators (Aguirre Velasco *et al.*, 2020). Another review focusing on adults looked at help-seeking behaviors related to mental health needs (Adams *et al.*, 2022). The most frequently reported influencing factors included patients' attitudes and perceived behavioral control, both of which were significant predictors of help-seeking intentions (Adams *et al.*, 2022). Other studies have identified additional factors which may play a significant role in influencing help-seeking behaviors. These include knowledge, financial resources, gender or occupation-specific stereotypes, and structural barriers/facilitators, such as place of residence (Gulliver *et al.*, 2010; Radez *et al.*, 2021; Randles & Finnegan, 2022). However, what remains unclear is the consolidated understanding of the help-seeking behaviours and barriers and facilitators to help-seeking among individuals who are in contact with mental health services. This is important to know since there may be unique interventions or supports available within the context of service delivery, which may differ from those aimed at individuals who have not sought care previously.

The overall aim of this rapid scoping review is to describe the barriers and facilitators to help-seeking for suicide prevention care among individuals who are in contact with and/or accessing mental health services in healthcare settings. Understanding these are essential for improving quality of care, reducing suicide risk, and ensuring that patient needs are met – all of which contribute to the ongoing improvement of mental health services. Furthermore, this review is part of a broader project aiming to inform a new iteration of a digital tool, which will be designed to support suicide prevention care for individuals in contact with mental health services. Before developing the new iteration of the tool, our goal is to identify currently unaddressed help-seeking needs among individuals who are in contact with mental health services.

A preliminary search of MEDLINE was conducted in March 2023, which did not identify any current or in-progress scoping or systematic reviews on this topic.

## Review questions

1. What are the characteristics of studies that investigate help-seeking needs related to suicide prevention care for individuals who are in contact with mental health services?
2. What are the barriers and facilitators of help-seeking related to suicide prevention care among individuals in contact with mental health services?

## Methods

We conducted a rapid scoping review, adapting the standard methodological guidelines for rapid (i.e., Cochrane Rapid Reviews Methods Group guidelines (Garritty *et al.*, 2021)) and scoping reviews (i.e., Joanna Briggs Institute (Peters *et al.*, 2015, 2020)). This type of review can be beneficial to inform urgently needed practice. In this case, the review was conducted to urgently inform a new iteration of a digital tool to support suicide prevention care in mental health services. Researchers employ various approaches to conduct rapid reviews without

compromising rigor, aiming to streamline the review process to meet the urgent needs (Tricco *et al.*, 2015). Here, we expedited the process by narrowing our search scope to the most relevant databases for the topic, establishing strict eligibility criteria, involving two independent reviewers in titles, abstracts, and full-text screening processes, and excluding the assessment of study quality. There was no a priori protocol registered, and we prepared this review report adhering to the Preferred Reporting Items for Systematic Reviews and Meta-Analyses extension for Scoping Reviews guidelines (PRISMA-ScR) (Tricco *et al.*, 2018).

## Eligibility criteria

### Concept

The primary concepts under investigation were suicide, suicidal ideation/thoughts, and suicide attempts. We followed the international definitions suggested by De Leo *et al.* (2021) to define the above suicide phenomena (De Leo *et al.*, 2021). Studies examining non-suicidal self-injury (i.e., self-harm behaviours and injuries without suicide intent) were ineligible for inclusion. However, in some studies, suicide attempts were identified by self-harm codes (e.g., in emergency department records). To be included, studies were required to have at least one of these items as an outcome of interest. Additionally, studies were expected to describe help-seeking needs, barriers or facilitators to help-seeking, or unmet needs related to suicide prevention. Help-seeking was defined as a planned behaviour of actively seeking help from a healthcare professional (or crisis line worker) initiated by recognizing an issue or changes in health, in this case relating to mental health (Cornally & McCarthy, 2011). Help-seeking for mental health is influenced by a combination of social, individual, and structural factors, as mental health concerns are intricately tied to their surroundings and seeking help is navigated through social engagement and cultural practices (Adams *et al.*, 2022; Jang *et al.*, 2007; Martinez *et al.*, 2020; Mojtabai, 2009).

### Population and Context

Herein, we define mental health services contact as either a visit or a phone call to any mental health care professionals in healthcare settings. This typically indicates that individuals are actively engaged with or seeking assistance from healthcare providers or institutions, and it can also mean accessing services and receiving treatment. To be eligible for inclusion, studies needed to focus on individuals in contact with mental health services from healthcare settings, which could include in-patient, out-patient, primary care settings, emergency department, and crisis line services. We included emergency departments because individuals seeking mental health services can access care through the emergency department, where they undergo assessments by healthcare providers for evaluation, stabilization, counseling, medication, or referral to specialized mental health services. Additionally, we included crisis lines because they offer a way to connect individuals in distress with trained responders, with a special focus on suicide prevention. However, it is important to acknowledge that contact with health services does not always result in the receipt of treatment, highlighting unmet help-seeking needs. Additionally, our primary interest was exploring help-seeking needs subsequent to contact with mental health services. When the timing of this contact was unclear, we determined temporality based on information provided by the authors. Studies were included if individuals were in contact with healthcare services either before or at the time of the study. However, studies focusing solely on individuals managing suicide-related thoughts and behaviors independently,

without utilizing any formal healthcare services and relying solely on self-help tools or informal carers (e.g., family or friends), were excluded.

## Search Strategy

Our search strategy was developed with a health science librarian and followed the PRESS guidelines (McGowan *et al.*, 2016). Before full searches were conducted, an initial limited search of MEDLINE was undertaken to identify relevant articles, and then text contained in the titles and abstracts alongside index terms of identified articles were used to inform development of the final search strategy. The search strategy, including keywords and index terms, was adapted for the following databases: MEDLINE, Scopus, CINAHL, PsycInfo, and EMBASE. Searches were conducted on 9<sup>th</sup> May 2023, and the full search strategies are provided in Supplementary File 1.

## Study selection

All records identified by database searching were collated and uploaded into Covidence, a software to support literature screening (“Covidence systematic review software,” 2019), and system-detected duplicates were automatically removed. Following piloting to ensure consistency in screening, titles and abstracts were screened by two independent reviewers (HDS, JK, SG, LBP, CP) against the inclusion criteria. Potentially relevant articles were retrieved in full, and two independent reviewers (HDS, JK, SG, LBP, CP) read each full-text articles for detailed inclusion assessment. Ineligible articles were excluded, and reasons for their exclusion were documented. Any interpretation disagreements that arose between the reviewers were resolved through team discussion.

## Data extraction

Data were extracted from included articles by two of the five reviewers (HDS, JK, SG, LBP, CP) using the data extraction tool on Covidence. Two independent reviewers initially piloted the tool (HDS, JK) using two articles to assess the correctness and completeness of the extracted data. After ensuring the consistency of data extraction, remaining articles were extracted by a single reviewer, and validated by a second reviewer. General characteristics of the article (e.g., author, publication country), design and methods including data sources, participant characteristics including considerations for intersectionality to report the prevalence of inequalities, outcome of interest, and barriers and facilitators for help-seeking, were extracted. See Supplementary File 2 for a full list of items in the data extraction tool. Any interpretation disagreements that arose during the validation step were resolved through discussion between reviewers.

## Data analysis and presentation

Data analysis was carried out independently by a single reviewer (HDS, JK, SG, LBP, CP) and validated by a second reviewer. We used a directed content analysis approach (Hsieh & Shannon, 2005) to characterize extracted narrative data. Data is presented narratively and in table format.

During analysis, participant characteristics were extracted and organized using the intersectionality framework (Crenshaw, 1989, 1991). The framework recognizes how social identities are interconnected and can lead to experiences of different levels of social power and positions, encompassing both privilege and oppression. As some groups, such as middle-aged men (Qin *et al.*, 2022), sexual minority groups (Kidd *et al.*, 2023), adolescents (Biswas *et al.*, 2020), and individuals with mental health conditions (Yeh *et al.*, 2019), have high prevalence of suicidal behaviours, we extracted data on these intersecting identities to gather a comprehensive understanding of unmet needs among subgroups of individuals in contact with mental health

services. During the extraction process, we recognized that some authors interchangeably used the terms, ‘gender’ and ‘sex’; for example, authors used women/men or female/male to define both gender and sex. To facilitate accurate reporting, we exercised our best judgment based on the categories as reported by the authors.

Extracted barriers and facilitators to help-seeking were organized using the adapted ecological model (McLeroy *et al.*, 1988), categorizing them into the following five distinct, yet not mutually exclusive levels: 1) Individual; 2) Interpersonal; 3) Organizational/Institutional; 4) Community and Societal; and 5) National Policy/Law. Individual factors encompassed participant characteristics such as knowledge, behaviors, skills, judgement, and attitudes including perceived opinions. Interpersonal factors encompassed interactive processes and relationships within primary social groups, whether formal or informal social networks, and support systems including families, workgroups, and friendship networks. Institutional and organizational factors encompassed characteristics of institutions and formal/informal operational rules and regulations, such as training support for clinicians in hospitals. Community and societal factors encompassed relationships among organizations, institutions, wider social networks and informal networks within defined boundaries. National, policy and law levels encompassed local, state, or national laws and policies, for example, health insurance concerns. It was necessary for reviewers to interpret information to a certain extent, relying on what the authors had reported. Differences in interpretation identified during the validation process were addressed through discussion between reviewers.

## Results

### Study inclusion

Our search strategy yielded 2,493 citations (Figure 1). After automatic removal of duplicates, 1,755 articles were screened based on title and abstract. Of these, 128 articles proceeded to full-text evaluation, ultimately resulting in 42 eligible studies. Reasons for exclusion were documented and they are outlined in the PRISMA flow chart (Figure 1).

<Insert Figure 1>

### Characteristics of included studies

Individual characteristics of included citations are organized in Table 1. The majority of studies were observational (n=19) and qualitative (n=17), followed by mixed/multi-methods (n=3), experimental (n=2), and quasi-experimental (n=1). Nearly half (n=19) of included studies were published between 2011 to 2020, and 13 were published within the last three years (2021-2023). Studies originated from the United States (n=16), United Kingdom (n=6), Australia (n=4), Canada (n=3), Sweden (n=3), Norway (n=2), Netherlands (n=2) and elsewhere in Asia, Europe, East Africa, and Oceania (see Table 2 for a summary of included studies). Suicide phenomena examined included suicide attempt (i.e., behaviour) (n=34), suicide ideation (n=26), and death by suicide (n=7). Data sources included interviews (n=23), surveys (n=14), health administrative data (n=8), and other sources (n=5), such as data obtained from text-based or call-line crisis services. Included studies commonly reported on demographic characteristics of participants including age (n=35), sex (n=28), marital status (n=17), gender (n=15), race (n=13), ethnicity (n=11), and income (n=10). Eighteen studies reported other characteristics such as previous mental health diagnosis, medical history, and employment status. See Figure 2 for a full list of characteristics reported in included studies.

<Insert Table 1>

<Insert Table 2>

<Insert Figure 2>

## Help-seeking needs

### Barriers to help-seeking

Included studies most commonly reported individual (n=28) and organizational (n=27) level barriers for help-seeking, followed by interpersonal (n=25), community (n=11) and policy/national level barriers (n=8). See Table 3. for a full list of examples, and the following describes the barriers in order from most common to least common. Many barriers spanned multiple levels of the socio-economic model; however, barriers are examined individually below.

*Individual Barriers* Barriers at the individual level included a lack of knowledge regarding where to seek help, or lack of awareness regarding own mental health (Chung, 2010; Cleary, 2017; Hom *et al.*, 2018; Jordan *et al.*, 2012; Kodama *et al.*, 2016; Kuramoto-Crawford *et al.*, 2017) alongside attitudes, often related to prior experiences of support. This included perceptions that support would not be effective (Adler *et al.*, 2020; Chia-Yi Wu *et al.*, 2012; Cleary, 2017; Heinsch *et al.*, 2020; Pavulans *et al.*, 2012), and a distrust of mental health services and professionals (Adler *et al.*, 2020; Hagen *et al.*, 2020; Hausmann-Stabile *et al.*, 2018; Holt *et al.*, 2023; Jones *et al.*, 2021; Skogstad *et al.*, 2006; Spence *et al.*, 2008). Further individual barriers included fear and apprehension, including worries about hospital presentation and involuntary hospitalization (Adler *et al.*, 2020; Holt *et al.*, 2023; Jones *et al.*, 2021; Jordan *et al.*, 2012; Pavulans *et al.*, 2012; Rheinberger *et al.*, 2021). A study examining the impact of previous mental health care on current disclosure of suicide risk found that men aged over 50 with a history of mental health inpatient care were more likely to explicitly not disclose current suicidal thoughts and behaviours than individuals who received outpatient or no previous care (Podlogar *et al.*, 2022), possibly reflecting fear of re-hospitalization. Additional fears include police involvement (Holt *et al.*, 2023), and potential loss of career (Adler *et al.*, 2020). Apprehension surrounding imposing emotional burden and distress on families was also identified (Chung, 2010; Heinsch *et al.*, 2020) where in some cases individuals did not want to seek help in case this resulted in family members discovering their experience with suicidality or other personal information about themselves such as sexuality (Holt *et al.*, 2023). Additional individual barriers identified included financial concerns regarding seeking help (e.g., missing work, not being able to afford out-of-pocket costs) (Chung, 2010; Heinsch *et al.*, 2020; Holt *et al.*, 2023; Hom *et al.*, 2018; Kuramoto-Crawford *et al.*, 2017), spiritual and cultural beliefs (Chung, 2010), and exacerbating mental health conditions, such as behavioural avoidance (Cleary, 2017; Lueck & Poe, 2021).

*Organizational Barriers* At the organizational level, prior negative experiences were cited as an important barrier preventing help-seeking. Such experiences included experiences of ‘dehumanization’, ‘alienation’ and ‘isolation’ during hospitalization, and having basic and cultural needs unmet (Adler *et al.*, 2020; de Lange *et al.*, 2022; Hausmann-Stabile *et al.*, 2018; Holt *et al.*, 2023; Jones *et al.*, 2021; Pirkis *et al.*, 2001; Spence *et al.*, 2008; Talseth *et al.*, 1999, 1999; Umubyeyi *et al.*, 2016). Furthermore, multiple studies identified perceived lack of knowledge and understanding among healthcare providers. This included needs related to mental health and suicide prevention (Camgan, 1994; de Lange *et al.*, 2022; Rheinberger *et al.*, 2021),

alongside needs related to individual's identities, for example sexual and gender identity (de Lange *et al.*, 2022). Some samples described being turned away from services, where some patients felt their needs were viewed by services as either 'not serious enough' or 'too complex' by healthcare providers (Adler *et al.*, 2020; McKay & Shand, 2018). Additionally, some samples identified that within emergency departments, physical rather than mental health issues were prioritised (Rheinberger *et al.*, 2021; Spence *et al.*, 2008). Further organizational barriers identified included language barriers (Chung, 2010), referral mechanisms (Jordan *et al.*, 2012), understaffing and long waiting times (Adler *et al.*, 2020; Rheinberger *et al.*, 2021; Spence *et al.*, 2008), the chaotic and rushed nature of settings such as emergency departments and inpatient units (Adler *et al.*, 2020; Rheinberger *et al.*, 2021; Talseth *et al.*, 1999), lack of privacy (Rheinberger *et al.*, 2021) and poor assistance post-discharge (Camgan, 1994; Heinsch *et al.*, 2020; Rheinberger *et al.*, 2021).

*Interpersonal Barriers* Several interpersonal level barriers were identified as influencing individuals' willingness to seek help. Stigma was commonly cited as a key barrier to help-seeking. Participants expressed concerns about being perceived as 'weak' or 'weird' by others (Adler *et al.*, 2020; Cleary, 2017; Hausmann-Stabile *et al.*, 2018; Heinsch *et al.*, 2020; Holt *et al.*, 2023; Hom *et al.*, 2018; Jordan *et al.*, 2012; Umubyeyi *et al.*, 2016). This was particularly pronounced among men and some occupational groups such as the military and firefighters. Furthermore, individuals feared being perceived or treated differently or blamed by peers and colleagues following disclosure of distress (Adler *et al.*, 2020; Chia-Yi Wu *et al.*, 2012; Hom *et al.*, 2018; Jordan *et al.*, 2012). Negative interpersonal experiences with medical professionals, marked by a superficial nature, lack of compassion and empathy, alongside sometimes stigmatising views also led to feelings of frustration and in some cases, reluctance to seek professional help (Camgan, 1994; Chia-Yi Wu *et al.*, 2012; Hausmann-Stabile *et al.*, 2018; Holt *et al.*, 2023; Rheinberger *et al.*, 2021; Spence *et al.*, 2008). Furthermore, while informal caregivers were described as having the potential to provide support, negative reactions from the caregivers were also at times described as contributory to reduced help-seeking behaviours (Spence *et al.*, 2008). After a suicide attempt, individuals varied in their willingness to confide in family and friends, reflecting an ongoing hesitation to disclose stressors due to concerns of creating emotional burden (Chung, 2010; Spence *et al.*, 2008). However, one study which examined suicide attempt disclosure among veterans found that although many had experienced unhelpful reactions (more commonly from romantic partners and friends), such reactions were not associated with reported likelihood of seeking help for suicidal thoughts or behaviours in the future (Ammerman *et al.*, 2021). Finally, some studies identified a lack of social connection or support system as a barrier to support (Hagen *et al.*, 2020; Holt *et al.*, 2023; Renaud *et al.*, 2014; Talseth *et al.*, 1999).

*Community and National/Policy Barriers* Community-level barriers included a lack of resources, such as the absence of nearby hospitals for accessing care (Adler *et al.*, 2020; Barry *et al.*, 2023; Heinsch *et al.*, 2020; Holt *et al.*, 2023; Spence *et al.*, 2008), and lack of integration of public health suicide prevention initiatives in primary care settings (John *et al.*, 2020). For example, individuals with a rural place of residence experienced barriers (such as travel time) that negatively influenced help-seeking behaviours (Barry *et al.*, 2023). A study found that refugees in Sweden had lower rates of specialised healthcare both prior to and after a suicide attempt compared to Swedish-born individuals (Amin *et al.*, 2021). National/policy-level barriers beyond the community level included lack of health insurance (Chung, 2010; Kuramoto-Crawford *et al.*,

2017; Umubyeyi *et al.*, 2016), as healthcare coverage is governed at the national or federal level and varies across countries.

### Facilitators to help-seeking

Facilitators for help-seeking were often identified as the opposite to many of the barriers described above and were also not mutually exclusive. The most commonly reported facilitators in the included studies were within the interpersonal (n=22), individual (n=16), and organizational (n=15) domains, followed by community (n=10) and policy levels (n=1). See Table 3. for a full list of examples, and the following describes the facilitators in order from most common to least common.

*Interpersonal Facilitators* At the interpersonal level, friends and/or family played a crucial role in facilitating help-seeking by offering emotional support and encouragement to seek help (Adler *et al.*, 2020; Chia-Yi Wu *et al.*, 2012; Hagen *et al.*, 2020; Hausmann-Stabile *et al.*, 2018; Holt *et al.*, 2023; McKay & Shand, 2018). Sometimes this social support was critical when individuals chose not to, or did not feel able to seek help themselves (Barnes *et al.*, 2002; Heinsch *et al.*, 2020; Rheinberger *et al.*, 2021). In the case of professionals in the army, some stated support from command was instrumental to accessing support, however, some also recognised feeling that they were then treated differently following disclosure (Adler *et al.*, 2020). Peer support from those who had shared similar experiences also encouraged help-seeking behaviour and reduced perceived stigma (de Lange *et al.*, 2022; Jordans *et al.*, 2018). Past positive interactions with healthcare professionals, where individuals had rapport in a trusting, caring, confidential, and respectful relationship motivated service users to seek help or disclose their distress (Adler *et al.*, 2020; Chia-Yi Wu *et al.*, 2012; Chung, 2010; Hagen *et al.*, 2020; Hausmann-Stabile *et al.*, 2018; Holt *et al.*, 2023; Jones *et al.*, 2021; McKay & Shand, 2018; Rheinberger *et al.*, 2021; Talseth *et al.*, 1999). In one study, veterans rated mental health care professionals as the most helpful person to disclose to regarding their experience of a prior suicide attempt. Among this sample, reported positive reactions to disclosure was positively associated with reported likelihood of disclosing their experience to others in the future, but not with reported likelihood of future help-seeking (Ammerman *et al.*, 2021). Positive experiences such as being acknowledged and treated as valued individuals by healthcare professionals, and staff members acknowledging the socio-cultural needs of patients were also facilitators (Chung, 2010; Hagen *et al.*, 2020; Holt *et al.*, 2023). However one study, which included individuals currently imprisoned, reported that individuals who had no prior contact with a prison psychologist tended to have higher intentions to seek future help for mental health concerns including suicidal thoughts than those with contact (Skogstad *et al.*, 2006). Another study described a text messaging intervention that promoted help-seeking behaviours whereby texts including information about social welfare services and reminders about medical appointments were sent (Kodama *et al.*, 2016).

*Individual Facilitators* At the individual level, having positive attitudes or confidence (Ilgen *et al.*, 2021; Skogstad *et al.*, 2006), capability to search for help from an online source or the community, knowing where to seek help (Ilgen *et al.*, 2021; McKay & Shand, 2018; Voros *et al.*, 2022), self-awareness of their own mental health symptoms (Chia-Yi Wu *et al.*, 2012; Chung, 2010) and desire and willingness to seek help (Rainbow *et al.*, 2023; Skogstad *et al.*, 2006) acted as facilitators. It is interesting to note that in one study, attitude was the strongest predictor for help-seeking while suicide ideation measured on Suicidal Ideation Questionnaire was not associated with intentions to seek help (Skogstad *et al.*, 2006). It was discussed in one study how

previous positive experience in mental health services could lead to positive attitudes for future help-seeking (Holt *et al.*, 2023). Individual's sense of autonomy, believing that they are in control of illness, was also important for help-seeking behaviours (Hagen *et al.*, 2020). Coping strategies used during crisis or mental health challenges were important in supporting individuals during future help-seeking behaviours (Jordan *et al.*, 2012; Rainbow *et al.*, 2023).

*Organizational Facilitators* At the organizational level, holistic and supportive care alongside provision of detailed mental health assessments was reported as promoting help-seeking within mental health services (Hagen *et al.*, 2020; Rheinberger *et al.*, 2021). In addition, normalization of the presence of suicidal ideation and taking time to find out where these thoughts came from was helpful (de Lange *et al.*, 2022). Young adults who identified themselves as sexual and gender minority group members reported that asking relevant and inclusive questions about sexual orientation, gender identity, and related characteristics was perceived as essential when accessing informal or formal mental health care (de Lange *et al.*, 2022). Individualized care, tailored to each person's unique needs and circumstances, also enhanced the likelihood of engagement with mental health services by addressing specific challenges. Follow-up services, including ongoing support and follow-up appointments, reinforced the idea that individuals are valued and cared for beyond their initial crisis, encouraging continued engagement with mental health resources (Adler *et al.*, 2020; Cleary, 2017; Holt *et al.*, 2023; Jordan *et al.*, 2012).

*Community Facilitators* At the community level, a social environment where mental health and suicide are openly discussed can reduce stigma and normalize help-seeking behaviours (Chia-Yi Wu *et al.*, 2012; Raingruber, 2002). Having easily accessible mental health services encourage individuals to seek help (Umubyeyi *et al.*, 2016). Access to community-based support systems (Jordan *et al.*, 2012), including community centers, mental health education programs, and support groups foster a sense of belonging and social interaction, which breaks down barriers to seeking help. Informal support networks consisting of neighbours, and even 'strangers' provide emotional support and encouragement for individuals to seek help (Chung, 2010). Moreover, the promotion of crisis hotlines (Karras *et al.*, 2017), along with disseminating information about available assistance resources was one of the ways to increase individuals' knowledge of where to go when in need of help. While rurality of residence was reported as a barrier to help seeking behaviours due to limited access to services, rurality was reported as one predictor of using hotline services (Thompson *et al.*, 2018). At the national level, a study identified the accessibility of financial benefits as a facilitative factor. These benefits played a crucial role in alleviating participants' stressors and enabling them to take time off from work, as directed by their mental health providers (Chung, 2010).

<Insert Table 3>

## Discussion

This scoping review identified 42 empirical studies that described the suicide-related help-seeking needs of individuals who are in contact with and/or accessing mental health services in a range of healthcare settings, such as in-patient, outpatient, emergency, and crisis line services. The majority of articles were published between 2011 and 2020, and 13 articles were published within the past three years (2021-2023). Almost all studies focused on suicide attempts and/or ideation as suicide phenomena. Authors commonly described characteristics of participants' age, sex, marital status, and gender. Barriers and facilitators to help-seeking behaviors related to suicide prevention care among individuals in contact with mental health services were frequently

reported at individual, interpersonal and organizational levels. These barriers encompass a range of factors, including stigma, lack of awareness, and systemic deficiencies in healthcare provision. Conversely, facilitators include supportive relationships, positive attitudes, accessible services, community resources, and financial benefits.

An important observation from this review when examining participant-reported characteristics is the presence of reported indigeneity in the included studies. The current review focused on individuals who are in contact with health services to receive support for suicide-related thoughts and behaviors, and it is noteworthy that we found limited studies specific to Indigenous peoples among other racialized groups. There was one study from New Zealand that reported indigeneity, aiming to examine the help-seeking behaviors of prisoners seeking assistance from a prison psychologist for their suicidal feelings (Skogstad *et al.*, 2006). Indigenous peoples are at a higher risk of suicide, and these heightened risks are attributed to systemic marginalization, and the enduring effects of cultural and social disparities, all of which are deeply rooted in historical colonization (Pollock *et al.*, 2018). In addition, their experiences with health services impact their help-seeking behaviors, and some may avoid hospitals due to lack of trust (Coombes *et al.*, 2022; Mbuzi *et al.*, 2017). This observation may explain the scarcity of studies examining the help-seeking behaviors of Indigenous peoples who are already accessing care, posing important areas for further investigation in future research.

While the included studies lacked extensive discussion on how barriers and varying intersectional identities affect individuals differently, it is crucial to consider the intersectional perspective when interpreting the findings of this review. It is important to be mindful that some individuals may encounter more barriers when seeking help compared to others. Individuals who self-identified as sexual and gender minorities, relationships with peers and/or families, and asking inclusive questions played a critical role in facilitating help-seeking behaviours (de Lange *et al.*, 2022). This finding highlights the need to ensure practitioners' competency for working with diverse groups. Middle-aged men, especially those working in 'masculine' occupations such as the military, reported fear of being perceived as 'weak' as a barrier for seeking help (Adler *et al.*, 2020; Cleary, 2017). In addition, disclosing mental health needs can be more challenging in certain cultures due to the presence of a more pronounced stigma (Chung, 2010). Social attitudes towards mental health and suicide have made significant progress over the past decades, yet it is important to acknowledge that lingering stigma surrounding suicide and mental health still persists. The normalization of help-seeking is critical not only for men but for everyone. Healthcare institutions and the broader social environment should be encouraged to work collaboratively to provide safe and non-stigmatized spaces targeting marginalized groups with the aim of supporting and normalizing help seeking. Recommendations for anti-stigma include training healthcare professionals (Henderson *et al.*, 2014; Sreeram *et al.*, 2022) and launching public awareness campaigns (Pirkis *et al.*, 2019) to reach a wider societal audience.

The current literature also describes barriers to help-seeking from the perspectives of parents and healthcare professionals, and they provide valuable evidence relevant to the understanding of the findings of this review (Moskos *et al.*, 2007; O'Keeffe *et al.*, 2021). Parents' perceived barriers to help-seeking for their children included hopelessness, fear of being seen as 'weak', and feeling apprehensive about disclosing mental health needs (Moskos *et al.*, 2007). In addition, carers reported perceived feelings of judgment experienced by service users when seeking mental health help in an emergency department (Moskos *et al.*, 2007). Seeking mental health help in highly medicalized settings, such as an emergency department, made both caregivers and service

users feel as if they were being judged and perceived as ‘time wasters’, using resources unnecessarily, or being considered less worthy than those with physical health issues (Moskos *et al.*, 2007). A need for human connection and therapeutic interactions in healthcare setting was reported (Moskos *et al.*, 2007), which is consistent with our review findings of facilitators for help-seeking for individuals experiencing suicidal ideation and behaviours. Emergency department healthcare professionals also recognized the therapeutic value of a person feeling listened to; however, it was reported that the emergency department was not the right environment for therapeutic conversations (O’Keeffe *et al.*, 2021). This is also described elsewhere in the literature and explained that traditional emergency practice is deeply rooted in biomedical practice which may conflict with expectations of patients seeking mental health support (Shin *et al.*, 2020). For example, patients described formulaic question-and-answer risk assessments, which is often the way emergency department professionals practice, as an unhelpful way of addressing their needs; however, healthcare professionals reported feeling safer using such tools as they are fearful of blame if someone goes on to die by suicide (O’Keeffe *et al.*, 2021). It is important to acknowledge that emergency department professionals have the intention to assist, yet they often feel ‘powerless’ (O’Keeffe *et al.*, 2021). Emergency department professionals also recognized the complex nature of suicide ideation and behavior, yet they did not hold the belief that they could adequately address someone’s needs or effectively help them cease self-harm (O’Keeffe *et al.*, 2021).

A few studies were excluded from this review due to an ineligible context, as individuals were not in contact with health services seeking or accessing mental health care. These studies nonetheless provide valuable evidence relevant to the findings of this review. It was found that individuals presented to the emergency department less frequently during the pandemic for suicide ideation (Sass *et al.*, 2022; Sveticic *et al.*, 2021). Participants described feeling like a burden to others due to an awareness of all healthcare services struggling under the pressure of COVID-19 (Sass *et al.*, 2022). Digital tools can serve as a valuable tool to address the help-seeking needs of individuals, particularly those who are hesitant to visit hospitals, especially amidst pandemic situations and where there are concerns about being judged. Technologies offer a variety of platforms and solutions that enable individuals to seek help remotely, thereby minimizing the barriers linked to physical presence. Virtual mental health platforms, telemedicine services, and crisis helplines accessible via phone or text provide discreet channels for seeking assistance (Rassy *et al.*, 2021; Shin *et al.*, 2023). As demonstrated by the current review’s findings, communication through crisis lines was found to be helpful in disclosing mental health concerns and addressing needs (Ilgen *et al.*, 2021). These types of technologies not only preserve anonymity but also allow individuals to communicate from the comfort of their own environment, thus alleviating the fear of judgment often associated with face-to-face interactions (Lehtimaki *et al.*, 2021).

The frequency counts are not appropriate to infer hierarchy of barriers and facilitators we identified in this review. Additionally, this review did not perform meta-analysis to determine the overall effect of these barriers and facilitators of help-seeking behaviours. However, it is worth noting that barriers and facilitators span all levels, highlighting important considerations for informing suicide prevention efforts at multiple levels to remove barriers and promote facilitators. Technologies and digital tools can augment suicide prevention care in clinical settings and online assessments are often preferred and reliable means for assessing sensitive information such as suicidal thoughts and behaviors (Iorfino *et al.*, 2017). As we plan our next phase of the overarching project of informing the next iteration of a digital tool to support suicide

prevention care, it is critical to consider the identified barriers to help-seeking and the existing discrepancies in the adoption of digital tools. As such, one recommendation to address complex barriers such as stigma without exacerbating existing digital equity gaps is to work closely with individuals with lived experience to identify appropriate and effective interventions (Lyles *et al.*, 2023). Also, when looking at the existing apps for suicide prevention, 66 apps were identified from app stores, of which 35 apps were found in both iOS and Android app stores (Wilks *et al.*, 2021). These apps were assessed for their contents, such as the presence of a safety plan and crisis line access (Wilks *et al.*, 2021). However, it is also important to consider the list of barriers and facilitators outlined in Table 3 as design considerations where appropriate, including the use of inclusive language, fostering trust and transparency regarding data use, and ensuring the app is freely accessible. This approach is essential to prevent the replication of barriers to help-seeking using digital solutions.

Despite the valuable insights obtained from this rapid scoping review, limitations should be acknowledged. The expedited nature of the review process inherently led to trade-offs that might impact the comprehensiveness of findings. Without a quality assessment of included studies, we likely introduced studies of varied methodological quality. Additionally, the accelerated process led to the omission of grey literature searches, and search results may not have been as exhaustive as in other types of literature reviews (e.g., systematic). Finally, the review included solely English-language articles. This might have introduced publication bias and may not be representative of help-seeking behaviors and needs in non-English speaking countries.

## Conclusion

This review outlines the characteristics of studies that describe the suicide-related help-seeking needs of individuals in contact with mental health services in any healthcare settings. The majority of included studies were observational or qualitative in nature, varying in their details about the barriers and facilitators for seeking mental health support for suicide ideation and behaviors. Barriers and facilitators were detected across all levels of the adapted socio-ecological model. Reported barriers and facilitators were not isolated to one single level; instead, they interacted, underscoring the intricate and interrelated nature of help-seeking. Suggestions to address help-seeking needs identified by studies include use of inclusive language, fostering trust, and normalizing help-seeking behaviours. However, it is important to recognise that certain barriers, such as stigma, are deeply rooted and systemic in nature, representing challenges that have persisted for many years. As our research team moves forward with designing a new iteration of a suicide prevention digital tool, it is crucial to involve individuals with lived experience. This engagement will help identify and address barriers where appropriate and capitalize on facilitators.

Table 1. Study characteristics

Author, Year	Country of Origin	Design	Aim of Study	Sample Description	Suicide Phenomena	Health Services Setting	Data Source
(Adler <i>et al.</i> , 2020)	USA	Qualitative	Examine barriers to treatment among Army soldiers who experienced a recent suicidal crisis and had a history of deployment	12 army soldiers receiving psychiatric inpatient treatment	Suicide attempt/behaviour; Suicidal ideation	Inpatient psychiatric unit	Interview
(Amin <i>et al.</i> , 2021)	Sweden	Observational	Investigate if the patterns of inpatient and specialised outpatient psychiatric and somatic healthcare use differ between refugees and Swedish born individuals 3 years before and after a suicide attempt  Examine whether healthcare use differs among refugees as a result of sex, age, education or receipt of disability pension	85,771 individuals who had attempted suicide and were treated by specialist healthcare  (81,916 Swedish-born, 3,855 refugees)	Suicide attempt/behaviour	Specialist healthcare services (inpatient and outpatient)	Health admin
(Ammerman <i>et al.</i> , 2021)	USA	Observational	Explore how experiences and reactions related to disclosing a prior suicide attempt relates to future help-seeking outcomes	37 veterans with previous suicide attempt receiving psychiatric inpatient treatment	Suicide attempt/behaviour	Inpatient psychiatric unit	Survey
(Barnes <i>et al.</i> , 2002)	USA	Observational	Describe the help-seeking behaviors engaged in by adolescents and young adults prior to a nearly lethal suicide attempt	153 adolescents and young adults (aged 13-34) treated at an emergency hospital following a suicide	Suicide attempt/behaviour	Emergency department	Survey

			Examine the association between help-seeking behaviors and nearly lethal suicide attempts	attempt			
(Barry <i>et al.</i> , 2023)	Canada	Observational	<p>Determine the number of individuals who seek help prior to suicide or a suicide attempt, separated by urban or rural status</p> <p>Examine the association between rurality and help-seeking among individuals who have died or attempted suicide</p>	<p>9,848 individuals who died by suicide identified through emergency department data and verified by coronial data.</p> <p>82,480 individuals who attempted suicide and presented to an emergency department</p>	Death by suicide; Suicide attempt/behaviour	Emergency department	Health admin (coronial data for death by suicide)
(Camgan, 1994)	UK (Northern Ireland)	Qualitative	<p>Investigate the psychosocial needs, of individuals who have attempted suicide by self-poisoning</p> <p>Evaluate healthcare support received during and following the suicide attempt</p>	6 individuals who were in hospital following a suicide attempt by intentional overdose	Suicide attempt/behaviour	Emergency department	Interview
(Cedereke & Öjehagen, 2007)	Sweden	Qualitative	Examine formal and informal help related to clinical and social needs that patients who attempted suicide received the	140 individuals who had been treated at a medical emergency inpatient unit	Suicide attempt/behaviour	Medical emergency inpatient unit	Interview

			<p>year following their suicide attempt</p> <p>Examine whether help from services was perceived to be adequate by patients</p> <p>Investigate whether patients who had repeat suicide attempts during the follow-up differed from those who did not</p>	following a suicide attempt			
(Chia-Yi Wu <i>et al.</i> , 2012)	Taiwan	Qualitative	Explore how and why people with deliberate self-harm access formal or informal help sources and related factors	20 individuals who presented to the emergency department following self-harm and were referred to a suicide prevention center	Suicide attempt/behaviour	Suicide prevention centre following emergency department presentation	Interview
(Chung, 2010)	USA	Qualitative	Examine the interplay of informal and formal help-seeking processes within a sample of Chinese immigrants in the USA	31 Chinese immigrants who enrolled for treatment at a mental health clinic following a suicide attempt after re-settling in USA	Suicide attempt/behaviour	Mental health clinics	Interview
(Cleary, 2017)	Ireland	Qualitative	Examine psychiatric service use and attitudes to treatment among a sample of men who made a medically serious	52 men who presented to three hospitals in Ireland following a medically serious	Suicide attempt/behaviour	Emergency department, inpatient psychiatric unit,	Interview

			suicide attempt.	suicide attempt.		outpatient services	
(de Lange <i>et al.</i> , 2022)	Netherlands	Qualitative	Explore experiences and needs related to formal and informal mental health care for sexual and gender minority youth who were experiencing suicidal ideation.	23 young adults who identified as sexual gender minority group (aged 18-35)	Suicide attempt/behaviour; Suicidal ideation	Most young adults interviewed received mental health care from a healthcare professional (e.g., psychologist, psychiatrist)	Interview; Focus group
(Denneson <i>et al.</i> , 2010)	USA	Observational	Describe health care contacts at a Department of Veterans Affairs medical center in Oregon in the year prior to the death of veterans by suicide	112 veterans who died by suicide in Oregon and had contact with a single Veterans Affairs Medical Centre in the year before their death	Death by suicide; Suicide attempt/behaviour; Suicidal ideation	Veterans Affairs Medical Center	Health admin
(Hagen <i>et al.</i> , 2020)	Norway	Mixed Methods	Explore how patients experience suicidality and their experience of being in a psychiatric hospital	11 women who were admitted to a psychiatric hospital and were experiencing suicidality	Suicide attempt/behaviour; Suicidal ideation	Psychiatric acute section	Interview; Other: Participant observation in the hospital.
(Hausmann-Stabile <i>et al.</i> , 2018)	USA	Mixed methods (Qualitative Report)	Examine the pathways related to and characteristics of services provided to adolescents following suicidal crisis, and examine what the adolescent's experiences of	68 Latina adolescents (aged 11-19) who had attempted suicide and had contact with medical and mental health services	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services (e.g., inpatient, outpatient)	Interview

			care				
(Heinsch <i>et al.</i> , 2020)	Australia	Qualitative	Explore the experience of individuals with comorbid depression and alcohol use disorders who had previously attempted suicide regarding the help they sought and received prior to and following the attempt	6 individuals with a prior suicide attempt who had participated in the Self-Help for Alcohol and other drug and Depression (SHADE) study	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services (e.g., mental health professional, phone helpline)	Interview
(Holt <i>et al.</i> , 2023)	USA	Qualitative	Explore the lived experience of sexual and gender minority individuals who have had a recent near fatal suicide attempt. Specific focus on help-seeking and previous mental health care experiences	22 individuals who identified as sexual and gender minority group and had reported at least one near-fatal suicide attempt in the past 18 months.	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services (e.g., inpatient, outpatient, helpline)	Interview
(Hom <i>et al.</i> , 2018)	USA	Observational	Identify the rates of professional and nonprofessional mental health service use and help-seeking, alongside preferred sources of support among female firefighters with a history of suicidality  Identify possible barriers to treatment seeking for	119 female firefighters who have a history of suicidal thoughts, plans, or attempts	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services (e.g., psychologist, therapist, counselor, psychiatrist, and other medical providers including physicians and nurse	Survey

			psychological problems and correlates of mental health service use among this group			practitioners)	
(Ilgen <i>et al.</i> , 2021)	USA	Experimental	Analyze the immediate effect of the Crisis Line Facilitation intervention on self-reported help seeking for suicidal crisis among veterans.	301 veterans receiving psychiatric inpatient treatment for a recent suicidal crisis (defined as significant ideation, plan, and/or recent attempt requiring psychiatric hospitalization)	Suicide attempt/behaviour; Suicidal ideation	Crisis line and inpatient psychiatric care	Survey; Interview
(John <i>et al.</i> , 2020)	UK (Wales)	Observational	Examine the type and timing of healthcare contacts in individuals who died by suicide in Wales	5130 individuals who died by suicide identified using The Suicide Information Database-Wales  1721 suicide deaths were eligible for full-linked analysis	Death by suicide	Range of health services (e.g., general practice, emergency department, secondary care)	Health admin
(Jones <i>et al.</i> , 2021)	USA	Qualitative	Explore the impact of involuntary hospitalization on youth and young adult's trust, help-seeking and engagement with clinicians	40 youth and young adults (aged 16-27) who had been involuntarily hospitalized to a psychiatric hospital.	Suicide attempt/behaviour; Suicidal ideation	Psychiatric hospital	Interview
(Jordan <i>et al.</i> , 2012)	UK (Northern Ireland)	Qualitative	Determine the preferences, and key features and processes of appropriate services and clinical care for young men	36 formerly suicidal young men	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services (e.g., inpatient,	Interview

			who are suicidal			outpatient, community mental health nursing, counseling)	
(Jordans <i>et al.</i> , 2018)	Netherlands	Observational	Identify the prevalence of non-fatal suicidal behaviour within community and health facility based populations in five low- and middle-income countries	6470 individuals presenting at primary care facilities	Suicide attempt/behaviour; Suicidal ideation	Primary care	Survey
(Karras <i>et al.</i> , 2017)	USA	Experimental (Pilot)	Evaluate messaging strategies to enhance use of the Veterans Crisis Line	The overall Veterans Crisis Line call rate for all pilot city sites was 4.81 per 1,000 veterans (exact total call number not provided).	Suicide attempt/behaviour; Suicidal ideation	Crisis line	Other: Veteran Crisis Line call data.
(Kodama <i>et al.</i> , 2016)	Japan	Quasi-experimental	Assess a mobile phone intervention, with a focus on help-seeking and self-harming behaviours	30 psychiatric outpatients who had experienced suicidal ideation	Suicide attempt/behaviour; Suicidal ideation	Outpatient psychiatric care	Health admin; Survey
(Kuramoto-Crawford <i>et al.</i> , 2017)	USA	Observational	Examine self-reported reasons for not receiving mental health treatment among adults with suicidal thoughts in the past year  Examine whether sociodemographic characteristics and health	8400 American citizens completing the National Surveys on Drug Use and Health Experiencing suicidal ideation or previous attempt	Suicide attempt/behaviour; Suicidal ideation	Individuals considered seeking help but could not gain access due to various self-reported reasons	Survey

			insurance status was associated with reasons				
(Leavey <i>et al.</i> , 2016)	UK (Northern Ireland)	Observational	Examine predictors of health and social care service contact in the 12-month period prior to suicide and General Practitioner detection of suicidality	361 Suicide deaths recorded by the Coroner's Office	Death by suicide	General Practitioner services and a range of mental health services (e.g., nursing services, social workers, emergency services)	Health admin
(Lueck & Poe, 2021)	USA	Observational	Identify psychological determinants of utilizing a helpline and examine potential barriers in order to inform effective help-line promotion	22 Students (currently in counseling)	Death by suicide	Helpline	Survey
(McKay & Shand, 2018)	UK	Qualitative	Examine the stories of adults who have previously attempted suicide including exploring experiences of Australian healthcare services	20 individuals who had attempted suicide in the previous 18 months	Suicide attempt/behaviour	Following suicide attempt, all but one individual received mental health care.	Interview
(Pavulans <i>et al.</i> , 2012)	Sweden	Qualitative	Explore the lived experience of being suicidal and having made a suicide attempt to identify potential implications for health care professionals concerning how to meet, care for and treat people who have made a suicide attempt and	10 individuals who had recently attempted suicide (within 3 weeks) and were receiving psychiatric inpatient treatment	Suicide attempt/behaviour	Inpatient psychiatric unit	Interview

			help them not to attempt suicide again				
(Pirkis <i>et al.</i> , 2001)	Australia	Observational	Examine the self-reported needs of users of mental health services who are suicidal (and non-suicidal), and examine whether these needs of met	245 individuals with suicidal ideation (from a total survey pool of 10,641 adults).	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services	Survey
(Podlogar <i>et al.</i> , 2022)	USA	Observational	Investigate whether certain level of past mental health care receipt is associated with later explicit nondisclosure of suicide risk to a health care professional  Explore whether severity of current suicidal ideation and other hypothesized psychological constructs (i.e., willingness to seek help for suicidal thoughts) may impact any associations	282 men aged 50+ with varied history of previous mental health care utilisation	Suicide attempt/behaviour; Suicidal ideation	Inpatient and outpatient mental health care	Survey
(Rainbow <i>et al.</i> , 2023)	Australia	Observational	Evaluate factor structure, internal consistency, convergent and divergent validity of Suicide-Related Coping Scale (SRCS) in two Australian online help-seeking samples	1,266 visitors to a mental health website who are experiencing suicidal ideation  693 users of a suicide safety planning mobile app	Suicidal ideation	Users of a suicide prevention mobile app, and visitors to a mental health website	Survey

(Raingruber, 2002)	USA	Qualitative	Explore issues that influence the care of depressed and suicidal individuals from the perspective of clients, licensed mental health professionals, primary care physicians, police officers, high school teachers, counselors, and parents	10 mental health care clients	Suicide attempt/behaviour; Suicidal ideation	Range of mental health services	Interview
(Renaud <i>et al.</i> , 2014)	Canada	Mixed methods	Determine what health care services were received by individuals who died by suicide, and what healthcare needs these individuals had	67 individuals who had died by suicide who were aged 25 or younger	Death by suicide	Range of health services (e.g., medical services, allied health, specialized mental health services, helpline, etc.)	Health admin; Interview
(Rheinberger <i>et al.</i> , 2021)	Australia	Qualitative	Understand the experiences of help seekers when presenting to the emergency department as a result of suicidal crisis. A focus on what works and doesn't work, and areas for improvement of care	17 individuals who had presented to a emergency department as a result of suicidal crises within the past 18 months	Suicide attempt/behaviour; Suicidal ideation	Emergency department	Interview
(Saini <i>et al.</i> , 2021)	UK (England)	Observational	Compare help-seeking among younger and older men who attended a therapeutic centre for men who are in suicidal crisis	546 Men attending a centre for men experiencing suicidal crisis.	Suicide attempt/behaviour	Suicide prevention centre	Health admin and survey; Other: Questionnaires completed with therapist during session
(Skogstad <i>et al.</i> , 2006)	New Zealand	Observational	Assess whether prisoners' help seeking intentions related to a personal-emotional problem,	527 male prison inmates	Suicidal ideation	Prison	Survey

			such as suicidal feelings, can be predicted using variables from the Theory of Planned Behaviour				
(Spence <i>et al.</i> , 2008)	Canada	Qualitative	Investigate the experiences including needs and barriers to care alongside substance use history of men who have repeat presentations to emergency departments following suicidal crises	25 males with suicide ideation or history of suicide intent with additional history of substance use problems, who had either been discharged from the emergency department, or admitted for inpatient psychiatric care	Suicide attempt/behaviour; Suicidal ideation	Emergency department	Interview
(Talseth <i>et al.</i> , 1999)	Norway	Qualitative	Explore the experiences of individuals with prior suicide attempts or ideation related to their lived experience of care receipt from mental health nurses	21 individuals receiving inpatient psychiatric care with previous suicide ideation or suicide attempt	Suicide attempt/behaviour; Suicidal ideation	Psychiatric inpatient hospital	Interview
(Thompson <i>et al.</i> , 2018)	USA	Observational	Examine help-seeking behaviors by adolescent and young adults for a national text-based crisis support service	Adolescent crisis line users. 849,483 crisis Text Line conversation records	Death by suicide; Suicidal ideation	Crisis text and phone line	Other: Text-based crisis service data
(Umubyeyi <i>et al.</i> , 2016)	Rwanda	Observational	Investigate help-seeking behaviours, barriers to care, and self-efficacy for help-	247 young adults (aged 20-35) who were experiencing	Suicidal ideation	Range of health services (e.g., health centre or a	Interview

			seeking among young adults with current depression and/or suicidality in a low-income setting	depression and/or suicidality		district hospital, trained mental health professional)	
(Voros <i>et al.</i> , 2022)	Hungary	Observational	Assess the internet use patterns among psychiatric inpatients, with a focus on suicide-related content and its impact on help-seeking	113 psychiatric inpatients with depressive disorders	Suicide attempt/behaviour; Suicidal ideation	Inpatient psychiatric unit	Survey
