# 27 SUMMARY

28	In response to exercise, protein kinases and signaling networks are rapidly engaged in skeletal muscle to
29	maintain energy homeostasis. High-intensity interval training (HIIT) induces superior or similar health-
30	promoting skeletal muscle and whole-body adaptations compared to prolonged, moderate-intensity
31	continuous training (MICT). However, the exercise intensity-specific signaling pathways underlying HIIT
32	versus MICT are unknown. Ten healthy male participants completed bouts of work- and duration-
33	matched HIIT and MICT cycling in randomized crossover trials. Mass spectrometry-based
34	phosphoproteomic analysis of human muscle biopsies mapped acute signaling responses to HIIT and
35	MICT, identifying 14,931 phosphopeptides and 8,509 phosphosites. Bioinformatics uncovered >1,000
36	phosphosites significantly regulated by HIIT and/or MICT, including 92 and 348 respective HIIT-specific
37	phosphosites after 5 and 10 min and >3,000 total phosphosites significantly correlated with plasma
38	lactate. This first human muscle HIIT signaling network map has revealed rapid exercise intensity-
39	specific regulation of kinases, substrates and pathways that may contribute to HIIT's unique health-
40	promoting effects.

# 53 INTRODUCTION

Exercise training confers numerous beneficial physiological adaptations in skeletal muscle, imparting a 54 wide range of whole-body health benefits that can prevent, delay and/or treat a range of chronic metabolic 55 56 conditions including obesity, type 2 diabetes and cardiovascular disease (Furrer et al., 2023a; Hawley et 57 al., 2014). Protein kinases and downstream signal transduction networks mediate these adaptations and 58 are activated/deactivated in contracting skeletal muscles in response to exercise in order to meet increased 59 energy and oxygen demands and maintain cellular energy homeostasis (Egan and Zierath, 2013; 60 Hargreaves and Spriet, 2020). Protein phosphorylation is a key post-translational modification that 61 regulates nearly all cellular biological processes, including skeletal muscle adaptations to exercise. These exercise-induced adaptations in skeletal muscle are influenced by factors such as the mode, intensity, 62 63 duration and frequency of exercise by engaging distinct molecular transducers (Hoffman, 2017). 64 High-intensity interval training (HIIT) has attracted widespread scientific and popular interest as 65 a low volume, time-effective exercise intervention capable of inducing superior (Milanovic et al., 2015) 66 or similar (Campbell et al., 2019) physiological adaptations (e.g., increased cardiorespiratory fitness) and 67 reductions in cardiometabolic disease risk factors compared to higher volume, moderate-intensity 68 continuous training (MICT). HIIT-based exercise protocols involve multiple (i.e., 4-10) work bouts of 69 high-intensity exercise (> 80% VO<sub>2</sub>max) interspersed with periods of rest or active recovery (Gibala et 70 al., 2012; MacInnis and Gibala, 2017). A single bout of HIIT activates several key exercise-regulated 71 kinases including the AMP-activated protein kinase (AMPK) and p38 mitogen-activated protein kinase 72 (p38MAPK) in skeletal muscle, stimulating mitochondrial biogenesis and leading to increased 73 mitochondrial content and enzyme activity in as little as 24 h post-exercise (Little et al., 2011; Perry et al., 2010). Relative to a workload-matched bout of MICT, a single bout of HIIT elicits similar skeletal muscle 74 exercise-induced increases in AMPK signaling (Trewin et al., 2018), as well as p38MAPK and p53 tumor 75 76 suppressor protein (p53) signaling responses that underpin mitochondrial biogenesis in human skeletal 77 muscle (Bartlett et al., 2012). Other studies of HIIT using acute intermittent Wingate testing (i.e., four allout 30 s exercise bouts interspersed with four min rest) report increased AMPK and p38 MAPK signaling 78

79 activation immediately post-exercise (Gibala et al., 2009), but failed to detect any differences in signaling 80 to key exercise-regulated kinases and gene expression responses involved in mitochondrial biogenesis compared to work-matched continuous exercise (Cochran et al., 2014). In contrast, increased activation of 81 82 key signaling pathways including AMPK, p38 MAPK and Ca<sup>2+</sup>/calmodulin-dependent protein kinase II 83 (CAMKII) has been detected in response to work-matched interval versus continuous exercise (Combes 84 et al., 2015). However, in-depth analyses of the signaling networks engaged by HIIT versus MICT are 85 lacking, with studies to date having analyzed only a subset of key exercise-regulated kinases, without 86 investigating the breadth of potential signaling pathways underlying each exercise intervention. 87 Global mass spectrometry (MS)-based phosphoproteomics has the capability of identifying and quantifying thousands of protein phosphorylation events occurring within the complex and interconnected 88 89 signaling networks engaged in response to exercise (Reisman et al., 2024). The first global 90 phosphoproteomic analysis of exercise signaling in human skeletal muscle uncovered > 1,000 sites 91 differentially phosphorylated after a short bout of continuous intense exercise (i.e., 8-12 min) versus rest 92 (Hoffman et al., 2015). More recently, Blazev et al. utilized phosphoproteomics to map human skeletal 93 muscle canonical signaling network responses to an acute bout of endurance (90 min cycling at 60% VO<sub>2</sub> 94 max), sprint (cycling all out for 3 x 30 s) and resistance exercise (6 sets of 10 repetition maximum knee 95 extensions) in eight healthy male participants, revealing 420 core phosphosites common to all exercise 96 modalities (Blazev et al., 2022). This study also identified divergent signaling responses to these different 97 modalities of exercise, although the exercise bouts were not matched for total workload nor duration. As such, it is difficult to isolate the divergent signaling responses related to exercise intensity, as kinase 98 99 regulation can display different time profiles of activation/deactivation (Blazev et al., 2022). Furthermore, 100 the common and unique kinases and downstream signaling pathways engaged by HIIT versus MICT in human skeletal muscle remain unexplored and no global phosphoproteomic analyses of HIIT-based 101 102 exercise have been performed to date. 103 Therefore, the overall aim of this study was to determine the temporal regulation of kinases and

104 downstream signaling pathways by an acute bout of HIIT versus MICT within the same human

105 participants while controlling for total exercise duration, workload and diet. We hypothesized that HIIT 106 would engage a unique subset of kinases and signaling pathways due to the intense, intermittent nature of 107 this exercise modality, including increased activation of signaling networks underlying mitochondrial 108 biogenesis. Utilizing a phosphoproteomic approach, this is the first study to map the human skeletal 109 muscle signaling networks underlying an acute bout of HIIT and across different work-matched exercise 110 intensities. We identify > 1,000 sites significantly regulated during (5 min) and immediately following 111 (10 min) HIIT and/or MICT, including known and novel exercise-regulated signaling events. 112 Furthermore, we identify a subset of kinases, substrates and pathways differentially regulated by HIIT 113 relative to MICT and highly associated with plasma lactate responses to exercise, revealing the molecular framework underlying adaptive responses to HIIT that become rapidly engaged and contribute to HIIT's 114 potent ability to stimulate unique muscle physiological adaptations and whole-body health benefits. 115 116 117 RESULTS Ten healthy male participants were recruited and successfully completed all preliminary testing and the 118 119 HIIT and MICT exercise bouts. The randomized crossover trial design permitted signaling responses to 120 workload- and duration-matched HIIT and MICT exercise to be mapped and interrogated within the same 121 participant (Figure 1A). Baseline whole-body anthropometric measurements and blood analyses confirmed these participants (age  $25.4 \pm 3.2$  y; BMI  $23.5 \pm 1.6$  kg/m<sup>2</sup>) were metabolically healthy, and 122 maximal exercise capacity testing confirmed they were recreationally active but relatively untrained 123 (relative peak oxygen uptake [VO<sub>2</sub>peak]  $37.9 \pm 5.2$  mL/kg/min) in line with our recruitment strategy to 124 maximize detection of skeletal muscle signaling responses to exercise (Figure 1B). Peak power output 125 (PPO;  $208 \pm 40$  W) was used to prescribe the relative work-matched intensities for HIIT and MICT 126 127 exercise. Lean mass from the DXA scan and resting metabolic rate (Figure 1B) were used to prescribe a 128 standardized meal for each participant to consume prior to each exercise trial day. 129 Following consumption of a standardized dinner the evening before each trial, blood and skeletal muscle biopsy samples were collected in the fasted state at baseline and at 5 min and 10 min of each 130

131	respective exercise bout (Figure 1A). Participants completing the acute bout of HIIT cycling, which
132	consisted of 5 x 1-min work bouts at $85 \pm 0.1\%$ of individual PPO ( $176 \pm 34$ W) with 5 x 1-min active
133	recovery intervals at 50 W, displayed increased plasma lactate concentrations at 5 and 10 min of exercise
134	relative to pre-exercise baseline (Figure 1C; $P < 0.0001$ and $P < 0.001$ , respectively; main effect of time
135	P < 0.0001) with no changes in plasma glucose levels (Figure 1D). In response to a total work- and
136	duration-matched acute bout of MICT (55 $\pm$ 2% individual PPO; 113 $\pm$ 17 W), participants displayed
137	increased plasma lactate concentrations at 5 and 10 min of exercise compared to baseline (Figure 1C; $P <$
138	0.001; main effect of time $P < 0.0001$ ) with no changes in plasma glucose concentrations (Figure 1D).
139	There was a main effect of higher plasma lactate levels in response to HIIT (Figure 1C; $P < 0.05$ ).
140	To map the signaling networks regulated by HIIT and MICT, proteins from each skeletal muscle
141	biopsy sample were extracted, reduced/alkylated, digested to peptides, and isobarically labeled prior to
142	phosphopeptide enrichment, fractionation and liquid chromatography with tandem MS (LC-MS/MS)
143	phosphoproteomic analysis (Figure 2A). Principal component analysis (PCA; Figure 2B) and
144	hierarchical clustering (Figure 2C) using the PhosR phosphoproteomic data analysis pipeline (Kim et al.,
145	2021a) revealed a high level of consistency in the overall baseline signaling signature at rest (0 min) prior
146	to the HIIT and MICT exercise trials, confirming our pre-exercise standardization strategies were
147	effective. Distinct clusters were observed in response to the two divergent exercise challenges, with the 5
148	and 10 min HIIT signaling profiles clustering farthest away from the pre-exercise control profile (Figure
149	<b>2B-2C</b> ). Overall, 19% of the total variance in the phosphoproteomic dataset was explained by principal
150	component (PC)1, while PC2 explained 6% of the variance (Figure 2B). Global phosphoproteomics
151	identified and quantified a total of 14,931 phosphopeptides (Figure 2D, Supplemental Table 1),
152	corresponding to 8,509 phosphorylation sites (Figure 2D, Supplemental Table 2).
153	Bioinformatic analyses of these phosphoproteomic data using PhosR (Kim et al., 2021a)
154	identified >1,000 phosphosites significantly regulated (-/+ 1.5-fold change; adjusted $P < 0.05$ ; identified
155	in $\geq$ 3 participants and $\geq$ 1 timepoint) by HIIT and/or MICT after 5 and 10 min, with < 400 of these sites
156	differentially regulated post- versus mid-exercise (Figure 2E; Supplemental Table 3). Significantly

157	regulated phosphosites observed in response to HIIT and/or MICT included kinases and substrates shown	
158	to be regulated by an acute bout of continuous high-intensity cycling such as those within the AMPK	
159	pathway (Hoffman et al. 2015; e.g., ACACB S222 (HIIT and MICT), AKAP1 S107 (MICT only),	
160	RPTOR S722 (HIIT and MICT), STBD1 S175 (HIIT and MICT; (Ducommun et al., 2019)), TBC1D1	
161	S237 (HIIT and MICT) and TBC1D4 S704 (5-min HIIT only)). Multiple substrates of protein kinase A	
162	(PKA; PHKA1 S1018 and HSBP6 S16) were increased by both HIIT and MICT, while the PKA substrate	
163	CDK16 S110 was only increased after 10 min of HIIT. In addition, the known Akt substrate IRS1 S629	
164	was only regulated after 10 min of both HIIT and MICT (Hoffman et al., 2015).	
165	In response to HIIT, a total of 1,697 phosphosites (Figure 3A; including 1,235 and 462 down-	
166	and up-regulated, respectively) and 2,127 phosphosites (Figure 3B; including 1,580 and 547 down- and	
167	up-regulated, respectively) were significantly regulated after 5 and 10 min of exercise, respectively	
168	(Figure 2E, Supplemental Table 3). The top 10 sites displaying the most robust increases in	
169	phosphorylation in response to HIIT at 5 min versus rest included MYLPF T10, ZAC S454, FGA S285,	
170	MTFP1 S129, EEF2 T59, MAPRE2 S229, LMNA T424, HRC T207, ADSSL1 S7 and MTFP1 S128. The	
171	10 phosphosites decreasing the most in response to HIIT at 5 min compared to rest included RTN4 S738,	
172	PDHA1 S262, DCLK1 S358, PDHA1 S201 and S269, SYNM T1109, MAP1B S1793, NGFR S217,	
173	SLC4A1 S349 and TRIP10 S354 (Figure 3A; Supplemental Table 3). After 10 min, top phosphosites	
174	most robustly increased by HIIT versus rest included CBX1 S89, MAPRE2 S229, MTFP1 S129, HRC	
175	T207, EEF2 T59, STBD1 S175, EEF2 T57, HRC S299, ZAK S454 and CIC S1371. Sites displaying the	
176	most decreased levels of phosphorylation by HIIT at 10 min included RTN4 S738, PDHA1 S201,	
177	SLC4A1 S349, KRI1 S142, NGFR S217, DCLK1 S358, CMYA5 S2825, TXNIP T294, CLASP2 S326	
178	and SRRMS S2398 (Figure 3B; Supplemental Table 3). A total of 352 sites were differentially	
179	regulated after 10 versus 5 min HIIT (Figure 2E), including 212 down- and 140 up-regulated	
180	phosphosites (Figure 3C; Supplemental Table 3).	
181	MICT induced changes in a lower number of significantly regulated phosphosites including a	
182	total of 1,158 phosphosites after 5 min (Figure 2E and 3D; 758 and 400 down- and up-regulated,	

183 respectively) and 1,125 phosphosites after 10 min (Figure 2E and 3E; 788 and 337 down- and up-184 regulated, respectively). A total of 110 sites were differentially regulated after 10 versus 5 min MICT, including 79 down- and 31 up-regulated phosphosites (Figure 2E and 3F; Supplemental Table 3). 185 To identify unique sites regulated by a single bout of HIIT relative to MICT, the signaling 186 187 responses to each exercise intensity were next compared. After 5 min of HIIT, 71 phosphosites were 188 down-regulated, while 21 phosphosites were up-regulated, relative to MICT (Figure 2E and 3G; 189 Supplemental Table 3). These exercise intensity-specific signaling responses to HIIT were observed to 190 be more robust at 10 min, with 275 phosphosites down-regulated and 73 phosphosites up-regulated 191 compared to MICT (Figure 2E and 3H; Supplemental Table 3). Top exercise intensity-specific phosphosites most robustly up-regulated by HIIT relative to MICT included MTFP1 S128/S129 192 (increased by 5 and 10 min HIIT; S129 also increased by 5 and 10 min MICT), MYL5 S20/S21/S25 193 194 (increased by 10 min HIIT; decreased by 5 min MICT) and TDRD9 Y546/S552 (increased by 10 min 195 HIIT: decreased by 5 min MICT). Exercise intensity-specific phosphosites down-regulated the most by 196 HIIT versus MICT included GP1BB T193 (decreased by 5 and 10 min HIIT; increased by 5 min MICT), 197 ATAD2B S374 (decreased by 5 and 10 min HIIT; decreased by 10 min MICT), MAPK1 T181 (decreased 198 by 5 min HIIT; not regulated by MICT), ADD2 S532 and GP1BA S606 (decreased by 5 and 10 min 199 HIIT; increased by 5 min MICT) and RYR1 T1399 (decreased by 5 and 10 min HIIT; decreased by 10 200 min MICT) (Figure 3G-H; Supplemental Table 3). 201 Kinase enrichment analyses were next performed to identify common and divergent

activation/deactivation of kinases in response to the two exercise bouts (**Figure 4A**). Kinase activities were inferred via direction analysis using kinase perturbation analysis (kinasePA; (Yang et al., 2016)), to annotate and visualize how kinases with at least five quantified known substrates were perturbed by each exercise intensity and timepoint. These analyses confirmed activation/deactivation of known exerciseregulated kinases in response to both HIIT and MICT relative to pre-exercise, with significant kinase activity enrichments considered as kinases displaying | z-score | > 1.6. Kinases displaying similar increases in the levels of inferred kinase activity in response to both HIIT and MICT after 5 and/or 10 min

209	included eukaryotic elongation factor 2 kinase (EEF2K), AKT1, AMPK alpha 1 catalytic subunit	
210	(PRKAA1), protein kinase cGMP-dependent 1 (PRKG1), and PKA subunit alpha (PRKACA),	
211	serum/glucocorticoid regulated kinase 1 (SGK1), ribosomal protein S6 kinase alpha-1 subunit	
212	(RPS6KA1), and MAP kinase-activated protein kinase 2 (MAPKAPK2). Moreover, exercise-induced	
213	decreases in the kinase activity of mammalian target of rapamycin (MTOR) were observed in response to	
214	both HIIT and MICT after 5 and 10 min. A strong trend for decreased kinase activity (i.e., z-score $\sim$ -1.6)	
215	of DNA-dependent protein kinase catalytic subunit (PRKDC) was also observed after 5 and/or 10 min of	
216	both HIIT and MICT.	
217	Kinase enrichment analyses also revealed unique kinases that were differentially	
218	activated/deactivated (i.e.,   z-score   > 1.6) in response to HIIT versus MICT after 5 and/or 10 min	
219	(Figure 4A). For example, activation of unique protein kinase C (PKC) conventional/atypical isoforms	
220	were observed to be differentially regulated by HIIT versus MICT, with increased activity of the	
221	conventional PKC alpha isoform (PRKCA; z-score > 1.6), as well as a strong trend for increased activity	
222	of the conventional PKC beta isoform (PRKCB; z-score ~ 1.6), in response to only 10 min HIIT. In	
223	contrast, activity of the atypical PKC zeta isoform (PRKCZ) was increased only by 5 and 10 min MICT	
224	(z-score > 1.6). Other kinases shown to be uniquely activated by HIIT or MICT and/or displaying strong	
225	trends for exercise intensity-specific activation included S6 kinase beta-2 subunit (RPS6KB2; increased	
226	only by 5 and 10 min HIIT; z-score $\geq$ 1.6), proto-oncogene tyrosine-protein kinase SRC (only increased	
227	by 10 min HIIT; z-score $\sim$ 1.6), large tumor suppressor kinase 2 (LATS2; only increased by 10 min	
228	MICT; z-score ~ 1.6), CAMK2A (increased only by 5 and 10 min MICT; z-score $\geq$ 1.6), large tumor	
229	suppressor kinase 1 (LATS1; only increased by 5 min MICT; z-score $\sim$ 1.6), and mitogen-activated	
230	protein kinase 12 (MAPK12; only decreased by 10 min HIIT; z-score ~ -1.6).	
231	Additional kinases that displayed unique and/or attenuated kinase activation trajectories in	
232	response to HIIT versus MICT but failed to reach significance in kinase enrichment analyses (Figure 4A;	
233	z-score   < 1.6) included serine/threonine kinase 38 (STK38) with attenuated levels of activation in	
234	response to MICT relative to HIIT. In addition, glycogen synthase kinase 3 beta (GSK3B), casein kinase	

235 2 alpha 1 (CSNK2A1), and ribosomal protein S6 kinase beta-1 subunit (RPS6KB1) all displayed trends for increased activation by HIIT with little or no activation detected in response to MICT. In contrast, 236 polo-like kinase 1 (PLK1) and novel PKC delta isoform (PRKCD) showed trends for decreased activation 237 in response to HIIT with little or no activation by MICT. Mitogen-activated protein kinase 11 (MAPK11) 238 239 displayed opposite trends of activation between exercise intensities, with a tendency for decreased 240 activation after 10 min of HIIT but increased activation after 5 min of MICT. 241 Pathway enrichment analyses were next performed using the Reactome database to determine 242 biological pathways that were enriched within the lists of significantly regulated genes (corresponding to 243 their respective phosphoproteins) for each exercise intensity and timepoint relative to pre-exercise, with significant enrichment considered as pathways displaying |z-score | > 1.6 (Figure 4B). Up-regulated 244 245 Reactome pathways (i.e., z-score > 1.6) enriched in response to both HIIT and MICT after 5 and/or 10 246 min included expected exercise-regulated biological pathways such as 'chromosome maintenance', 247 'transcription', 'opioid signaling', 'pyruvate metabolism and citric acid TCA cycle', 'glucose 248 metabolism' and 'gluconeogenesis'. Down-regulated Reactome pathways (i.e., z-score < -1.6) enriched in 249 response to both HIIT and MICT after 5 and/or 10 min included 'L1CAM interactions', 'PI3K Akt 250 activation' and 'platelet activation signaling and aggregation'. 251 The only Reactome pathway observed to be positively enriched in response to HIIT after 5 and/or 252 10 min but not enriched by MICT was 'RNA polymerase I and III and mitochondrial transcription' 253 (Figure 4B). The only two pathways observed to be negatively enriched in response to HIIT after 5 254 and/or 10 min but not MICT included 'P75 NTR receptor mediated signaling' and 'regulation of mRNA 255 stability by proteins that bind AU rich elements'. In contrast, Reactome pathways positively enriched in response to MICT after 5 and/or 10 min but not enriched by HIIT included 'integration of energy 256 257 metabolism', 'TCA cycle and respiratory electron transport', 'phospholipid metabolism', 'metabolism of 258 nucleotides', and 'fatty acid triacylglycerol and ketone body metabolism'. Pathways negatively enriched 259 in response to MICT after 5 and/or 10 min that were not enriched by HIIT included 'SLC mediated

transmembrane transport', 'GAB1 signalosome', '3' UTR mediated translational regulation', and 'gastrin
CREB signaling pathway via PKC and MAPK'.

Kinase-substrate associations were next predicted in response to HIIT and MICT via the 262 phosphoproteomic signaling profiles and kinase recognition motif of known substrates using kinasePA 263 264 (Figure 5; (Yang et al., 2016)). This analysis generated predictions matrices, with columns corresponding to kinases, rows corresponding to phosphosites, and values denoting how likely a phosphosite is 265 266 phosphorylated by a given kinase in response to HIIT (Figure 5A) and MICT (Figure 5B). Pathway 267 enrichment analyses were then performed using phosphosites with a high prediction score for each kinase 268 to observe how biological pathways containing substrate phosphosites are commonly and/or uniquely 269 regulated by HIIT (Figure 5C) versus MICT (Figure 5D). Collectively, these analyses revealed that a 270 range of kinases displayed unique patterns and/or significance levels of signaling pathway regulation in 271 response to each exercise intensity including HIPK2, GSK3B, CDK6, CDK2, CDK1, CDK7, MAPK14, 272 MAPK3, CHEK1, PRKCG, CDK5, PRKDC, PIM2, PRKCQ, PRKCD, CSNK2A1, PLK1, AKT1,

# 273 PRKCB and PRKCA (Figure 5C-D).

274 Using these matrices, signalome networks were then reconstructed based on the correlation 275 between kinases to visualize how kinases and substrates are regulated in response to HIIT (Figure 6A) 276 versus MICT (Figure 6B). This revealed distinct signalome profiles between HIIT and MICT, with 277 kinases clustered closer together more highly correlated in terms of their kinase-substrate predictions. To 278 determine the proportion of common and unique substrates targeted by specific kinases in response to 279 HIIT versus MICT, phosphoproteins were clustered into protein modules according to their prediction 280 matrices shown in Figure 5A-B. This clustering revealed five unique clusters of HIIT and MICT kinase-281 substrate signaling profiles (Supplemental Figure 1A-E; modules 1 to 5). Visualization of these five 282 clusters for individual kinases revealed shared or unique substrate signaling trajectories in response to 283 HIIT (Figure 6C) versus MICT (Figure 6D) within their unique signalome networks. For example, 284 widely studied exercise-regulated kinases including AKT1, CAMK2A, MAPK1, MAPK3, MTOR and PRKAA1 displayed similar substrate clusters between exercise intensities, while other kinases such as 285

ABL2, MAPK14, PLK1, PRKCA, PRKCE, RPS6KA1 and STK38 regulated unique substrate clusters in
 response to HIIT versus MICT (Figure 6C-D).

Finally, to demonstrate the utility of the global phosphoproteomic dataset and test the hypothesis 288 289 that higher plasma lactate concentrations during HIIT can influence which skeletal muscle exercise-290 regulated signaling proteins become engaged, correlation analyses were performed to interrogate 291 individual phosphorylation site responses within the dataset relative to the plasma lactate responses to 292 HIIT and MICT exercise. A total of 3,084 phosphosites were significantly correlated with plasma lactate 293 concentrations from each timepoint and exercise intensity (Supplemental Table 4: q < 0.05 with 294 Benjamini Hochberg false discovery rate (FDR)). Among these phosphosites, nine of the top 50 most significantly correlated phosphosites have annotated functional roles in regulating their respective 295 296 protein's activation state in the PhosphoSitePlus annotation database (Figure 7A-D; (Hornbeck et al., 297 2012)). For example, four of these top nine phosphosites that were significantly correlated with plasma 298 lactate have experimentally validated roles in governing their respective protein's activity and are 299 involved in regulating a range of key metabolic processes (e.g., glycolysis, glucose transport and 300 mitochondrial biogenesis) including PDHA1 S201 (Figure 7A), RPTOR S859 (Figure 7B), TFEB 301 S123/S128/S136 (Figure 7C) and TBC1D4 S588 (Figure 7D). Other phosphosites among the top 10% 302 most significantly correlated sites with plasma lactate concentrations included known AMPK-regulated sites (e.g., ACACB S222; mitochondrial fission regulator-1 like protein (MTFR1L) S141 (Tilokani et al., 303 304 2022)), as well as novel phosphosites with no known functional role (e.g., DENND4C S989, phosphoprotein present in glucose transporter GLUT4 vesicles; MTFP1 S128/S129, phosphoprotein 305 306 involved in inner mitochondrial membrane fission/fusion) that may respectively be involved in regulating skeletal muscle glucose transport and mitochondrial network dynamics in response to exercise. 307 308 309 DISCUSSION

310 For the first time, this analysis of the HIIT signaling network in human skeletal muscle has revealed the

early time course of acute signaling events underlying muscle adaptive responses to HIIT versus MICT.

Our global phosphoproteomic approach has revealed the rapid induction of a complex network of common and exercise intensity-specific kinases, substrates and pathways regulated by a single bout of HIIT versus work-matched MICT after just 5 min of exercise, that were highly correlated with the prevailing plasma lactate responses to each exercise intensity. To the best of our knowledge, this is the first phosphoproteomic study of exercise signaling that has matched for workload and duration to assess divergent signaling responses between exercise intensities.

318 The matching of total workload and duration between exercise bouts is important and contrasts 319 previous phosphoproteomic studies that have compared exercise signaling responses to divergent 320 workloads of differing durations and modalities (Blazev et al., 2022). Such an approach permitted 321 resolution of time-sensitive profiles of distinct signaling responses comparing the effects of a moderate-322 intensity continuous exercise challenge to a high-intensity interval-based exercise protocol within the 323 same participants in a crossover study design, allowing sufficient recovery (i.e., > 10 days) to ensure no 324 residual effects of the previous exercise bout. Standardized meal provision before each trial prescribed in 325 accordance with each participant's body composition, resting metabolic rate and food diary records led to 326 a highly reproducible resting 'baseline' signaling signature for each participant, confirming a high level of 327 control and reinforcing the importance of utilizing dietary standardization in addition to just overnight 328 fasting to help control for potential differences in nutrient/energy availability between trials.

329 This study utilized a metabolically healthy, but untrained participant cohort to induce robust 330 signaling responses, as available evidence indicates exercise-induced signaling responses in skeletal 331 muscle such as AMPK activation are more pronounced in untrained relative to trained human participants 332 (McConell et al., 2005; Yu et al., 2003). All ten participants were able to successfully complete both 333 work-matched exercise trials, with the HIIT protocol eliciting higher plasma lactate concentrations 334 compared to MICT. The two exercise intensities both provided a robust contractile stimulus that engaged 335 a range of known exercise-regulated kinases including activation of AMPK (regulated by AMP/ATP and ADP/ATP ratios), EEF2K (regulated by Ca<sup>2+</sup>/calmodulin), PKA (regulated by cAMP) and PRKG1 336 (regulated by NO/cGMP). Activation of AKT1 increased after 10 min (e.g., inferred via known substrate 337

IRS1 S629), while surrogate markers of MTOR activation decreased (e.g., NDRG2 T248 decreased only
after 10 min HIIT; NDRG2 S344 increased only after 5 and 10 min MICT), in response to both exercise
intensities. Overall, a higher number of phosphosites were down-regulated versus up-regulated at each
timepoint and exercise intensity, suggestive of acute exercise-regulated kinases becoming inhibited and/or
phosphatases becoming activated early after commencing exercise.

343 In this study mitochondrial fission process 1 (MTFP1; also known as MTP18) S128/S129 were 344 identified among the top HIIT-regulated sites, with S128 only regulated by HIIT and more robust 345 phosphorylation of S129 observed following HIIT versus MICT. The inner mitochondrial membrane 346 protein MTFP1 has known roles in mitochondrial fission/fusion and was previously identified as having increased abundance in rat diaphragm following endurance exercise training (Sollanek et al., 2017), but 347 has not been implicated in acute exercise signaling to date. MTFP1 has recently emerged as a key 348 349 regulator of liver mitochondrial and metabolic activity, with liver-specific deletion of MTFP1 in mice 350 conferring protection against high fat diet-induced metabolic dysfunction and hepatosteatosis via 351 upregulating oxidative phosphorylation activity and mitochondrial respiration (Patitucci et al., 2023). 352 MTFP1 has been identified as a gene target of the master regulator of skeletal muscle mitochondrial 353 biogenesis, the peroxisome proliferator-activated receptor gamma coactivator 1-alpha (PGC-1 $\alpha$ ), in 354 C2C12 myotubes (Nsiah-Sefaa et al., 2014) with its translation regulated by mTORC1 activity (Morita et 355 al., 2017). Human skeletal muscle MTFP1 gene expression, concomitant with PGC-1 $\alpha$  expression, was 356 recently shown to be reduced by leg immobilization and increased upon resumption of physical activity and resistance exercise training (Pileggi et al., 2023). Collectively, this growing body of evidence 357 358 suggests that unique phosphorylation of MTFP1 in response to HIIT may represent a novel mechanism 359 underlying exercise-regulated mitochondrial inner membrane fission and/or fusion. Further investigation 360 of MTFP1's potential functional roles in maintaining skeletal muscle mitochondrial networks and 361 metabolic homeostasis is warranted.

The observed differences in work-matched HIIT versus MICT signaling responses may be due to
 stochastic changes or accumulation of intracellular calcium and/or other metabolites in response to

364 fluctuating energy demands during HIIT's repeated work-rest cycles (Gibala and Hawley, 2017), and is 365 consistent with other studies investigating effects of acute work-matched bouts of HIIT versus MICT (Bartlett et al., 2012; Peake et al., 2014). Indeed, investigations that have determined metabolic 366 fluctuations occurring in work-matched interval versus continuous exercise have observed a greater level 367 368 of activation of kinases such as AMPK, CaMKII and p38 MAPK, suggesting that buildup of upstream 369 stimuli for these kinases (e.g., increased AMP/ATP and/or ADP/ATP ratios, intracellular calcium) may 370 trigger greater activation in response to interval-based exercise (Combes et al., 2015). While levels of 371 AMPK activation were similar between HIIT and MICT in this study, differential activation of PKC 372 conventional/atypical isoforms suggests potential influence of muscle intracellular calcium during HIIT. For example, activation of the atypical PKC isoform PRKCZ was only observed in response to 5 and 10 373 374 min MICT, supporting previous observations of human muscle PRKCZ phosphorylation and/or activation 375 in response to continuous cycling at ~70-75% VO2peak (Perrini et al., 2004; Rose et al., 2004), as rapidly 376 as the first 5 min after commencing exercise (Rose et al., 2004). The present study has revealed previously unappreciated exercise intensity-specific activation of calcium-responsive conventional PKC 377 378 isoforms (i.e., PRKCA, and a trend for increased activation of PRKCB) in response to HIIT, suggesting 379 intracellular calcium spikes during HIIT intervals may drive PKC isoform-specific activation. As no 380 further increase in atypical PKC isoform activity was observed in previous studies in response to 381 increased continuous exercise intensity (Richter et al., 2004), these data suggest the stochastic nature of 382 HIIT may govern its unique activation of PKC isoforms versus MICT. Furthermore, activation of the 383 calcium-responsive CAMK2A, which is rapidly activated in human muscle in response to continuous 384 exercise (Rose and Hargreaves, 2003; Rose et al., 2006), was differentially regulated by HIIT versus MICT (i.e., CAMK2A activity only increased by 5 min MICT). This suggests differential signaling 385 mechanisms underlying calcium homeostasis during continuous versus interval exercise may contribute to 386 387 HIIT's potent ability to stimulate mitochondrial biogenesis (Torma et al., 2019). Rates of carbohydrate oxidation are increased, while rates of fat oxidation are reduced, in 388

response to HIIT compared to MICT (Peake et al., 2014). HIIT increases levels of skeletal muscle glucose

390 transport, glycogenolysis and glycolysis, leading to accumulation of glycolytic products such as muscle 391 lactate that can act as signaling molecules and influence exercise-regulated signaling networks within 392 skeletal muscle, as well as be released into the bloodstream to facilitate interorgan communication with 393 other tissues such as the heart, liver and brain (Brooks et al., 2023; Hargreaves and Spriet, 2020). Plasma 394 lactate responses to HIIT in the present study were increased relative to MICT, with > 3000 phosphosites 395 identified as being significantly correlated with the prevailing plasma lactate concentrations. Among the 396 most highly correlated phosphosites with plasma lactate were PDHA1 S201 (Figure 7A) and TBC1D4 397 S588 (Figure 7D) with annotated functional roles in the regulation of glycolysis and glucose transport, 398 respectively. PDHA1 is a subunit of the PDH enzyme complex, which is regulated by pyruvate and ADP 399 and becomes activated by calcium during exercise, serving as a key link between glycolysis and the 400 tricarboxylic acid (TCA) cycle by converting pyruvate to acetyl-CoA (Hargreaves and Spriet, 2020). 401 TBC1D4 is a key nexus in skeletal muscle glucose transport regulation via controlling glucose transporter 402 GLUT4 translocation in response to insulin and muscle contraction during exercise (Cartee, 2015). Given 403 the strong associations (i.e., |r| > 0.80) observed between plasma lactate concentrations and these key 404 regulatory phosphosites in the present study, and in light of other studies investigating signaling-405 metabolite correlations in response to distinct exercise modalities and workloads (Blazev et al., 2022), 406 these correlation data support the hypothesis that lactate accumulation in skeletal muscle and/or blood is a 407 major driver of exercise intensity-specific physiological adaptations (MacInnis and Gibala, 2017). 408 Collectively, differences in muscle and circulating metabolites and counterregulatory hormones in 409 response to HIIT versus MICT may therefore influence metabolite-protein interactions during/after 10 410 min of exercise, leading to exercise intensity-specific signaling events and unique physiological 411 adaptations. In addition to increasing plasma lactate concentrations, the higher exercise intensity of HIIT 412 versus MICT may also lead to differential muscle fiber type recruitment that in turn influences fiber type-413 specific signaling pathway responses such as AMPK (Kristensen et al., 2015), which were undetectable 414 given the present study's focus on analyzing whole muscle biopsy samples.

415 There are several limitations of this first global study of the HIIT signaling network that warrant 416 further investigation in future studies of human skeletal muscle exercise signaling. First, this study involved only male participants to allow us to benchmark observed signaling responses to previous 417 418 studies investigating continuous exercise protocols in males. The acute responses of skeletal muscle to 419 HIIT in female human participants remain uncharacterized and are being actively investigated in our 420 ongoing research. The HIIT and MICT protocols utilized were selected based on the feasibility of 421 untrained participants to complete each exercise bout. As a result, 5-10 min of HIIT or MICT at the 422 prescribed intensities may not have engaged the full repertoire of shared and exercise intensity-specific 423 signaling pathways in muscle and may require longer exercise durations in future studies. For example, patterns of substrate oxidation change during more prolonged exercise and differ between sexes, which 424 425 may affect signaling responses more robustly between exercise intensities and/or sexes.

426 The signaling responses and programmed muscle adaptations to an acute bout of HIIT or MICT 427 may also not be able to predict chronic training adaptations (Hawley et al., 2018). For example, recent 428 transcriptomic and proteomic analyses of mammalian skeletal muscle have highlighted that acute changes 429 may not be predictive of chronic exercise training-induced changes (Furrer et al., 2023b), such as HIIT-430 induced remodeling of the skeletal muscle proteome after repeated training (Hostrup et al., 2022; 431 Robinson et al., 2017). Extensive total proteome analysis was not performed in this study, as only 5-10 432 min of exercise has been previously observed to not affect total muscle protein content (Hoffman et al., 433 2015). While not analyzed, given the acute nature of the exercise bouts in this study, repeated HIIT 434 training (i.e., six sessions per week for two weeks) can stimulate more robust mitochondrial adaptations 435 (i.e., greater exercise-induced increases in citrate synthase maximal activity and mitochondrial 436 respiration) compared to total work and duration-matched MICT in human skeletal muscle, suggesting 437 that exercise intensity and/or the pattern of muscle contraction may drive peripheral adaptations to 438 exercise (MacInnis et al., 2017). The amplification of human skeletal muscle signaling and mRNA 439 responses underlying mitochondrial biogenesis in response to acute low-volume, high-intensity exercise may be due to more robust induction of metabolic stress relative to more prolonged, moderate-intensity 440

exercise (Fiorenza et al., 2018; MacInnis and Gibala, 2017). In this regard, it has been speculated that
accumulation of skeletal muscle intracellular AMP, ADP, calcium and/or other metabolites such as lactate
during HIIT intervals may differentially affect skeletal muscle signaling responses and adaptations to
exercise such as mitochondrial biogenesis relative to continuous bouts of exercise (MacInnis et al., 2019).
However, with repeated chronic HIIT versus MICT training, exercise training volume may become more
important than intensity in increasing skeletal muscle mitochondrial content over time (Bishop et al.,
2019).

Finally, the functional relevance of HIIT and/or MICT regulation of unique kinase activation 448 patterns including isoform-specific PKC activation and novel HIIT-regulated phosphosites such as 449 MTFP1 S128/S129 remains unknown. Functional validation experiments (e.g., target knockdown, 450 overexpression and/or mutagenesis) in cellular and/or animal models are required to determine their 451 452 respective roles in regulating exercise-induced muscle adaptations and molecular processes, such as 453 MTFP1's potential functional role in regulating inner mitochondrial membrane fission/fusion in response 454 to acute exercise. Regardless of these considerations, the present study has uncovered a previously 455 unknown breadth of shared and exercise intensity-specific molecular machinery engaged by a single bout 456 of HIIT versus MICT in untrained healthy males. Unique exercise signaling pathways and molecular 457 transducers uncovered within these HIIT and MICT signaling networks can ultimately be leveraged and 458 reinforced with longer interventions and/or repeated exercise training to stimulate cardiometabolic health-459 promoting effects and help combat a range of chronic metabolic conditions in populations with disease.

511	characteristics, and plasma lactate and glucose responses to HIIT and MICT. As detailed in the		
512	overall study schematic (A), participants first underwent preliminary testing and dietary control prior to		
513	each experimental HIIT or MICT trial day. Participants arrived at the laboratory following overnight		
514	fasting for baseline measurements, a dual-energy x-ray absorptiometry (DXA) body composition scan and		
515	resting metabolic rate (RMR) testing. Each participant then completed an incremental fitness test to		
516	volitional fatigue on a cycle ergometer to determine peak oxygen uptake ( $\dot{V}O_2$ peak) and peak power		
517	output (PPO) to calculate the work rate for the subsequent two workload (67.9 $\pm$ 10.2 kJ) and total		
518	duration (10 min) matched HIIT and MICT exercise trials. Participants' food and fluid intake for all		

519 meals and snacks was recorded over a three-day period using a mobile phone application and analyzed by an accredited research dietician. A standardized dinner was consumed by each participant the evening 520 521 prior to each exercise trial, with no caffeine or alcohol consumed 24 h prior. In a randomized crossover 522 design, participants were randomly assigned their first exercise trial (i.e., HIIT or MICT) prior to 523 commencing trial days and did not perform any exercise in the 72 h prior to each trial day. HIIT and 524 MICT exercise trials were separated by at least a 10-day recovery period. On each experimental day, 525 participants reported to the laboratory following overnight fasting, and vastus lateralis skeletal muscle 526 biopsies and venous blood samples were collected pre-exercise (0 min), mid-exercise (5 min) and 527 immediately post-exercise (10 min). Participant characteristics are listed in (B). Plasma (C) lactate and 528 (**D**) glucose concentrations in response to HIIT versus MICT were determined using a YSI Analyzer. 529 Data are presented as mean  $\pm$  SD; two-way ANOVA with repeated measurements, Tukey's test for 530 multiple comparisons; \*\*\* P < 0.001 vs. 0 min; \*\*\*\* P < 0.0001 vs. 0 min; # P < 0.05 vs. 5 min; n=10 531 for each exercise intensity and timepoint.

532

533 Figure 2. Human skeletal muscle phosphoproteomic analysis reveals effective pre-exercise 534 standardization and distinct signaling profile clusters in response to HIIT versus MICT after 5 and 535 10 min. Vastus lateralis skeletal muscle biopsies were collected pre-exercise (0 min), mid-exercise (5 536 min) and immediately post-exercise (10 min) from each participant during the HIIT and MICT exercise 537 trials (A). The 10-min HIIT cycling session consisted of alternating 1-min intervals at  $85 \pm 0.1\%$  of individual Wmax ( $176 \pm 34$  W) and 1-min active recovery intervals at 50 W. The total duration- and 538 539 work-matched MICT cycling session consisted of 10 min cycling at  $55 \pm 2\%$  of individual Wmax (113  $\pm$ 17 W). Each of the 60 total muscle biopsy samples were prepared and subjected to LC-MS/MS analysis 540 to accurately identify and quantity skeletal muscle protein phosphorylation sites at 0 min (pre-exercise), 5 541 542 min (mid-exercise) and 10 min (post-exercise) for both the HIIT and MICT exercise trials (A). Principal 543 component analysis (B) and hierarchical clustering (C) of the phosphoproteomic datasets resulting from LC-MS/MS analysis of the 60 muscle biopsy samples was performed using the PhosR phosphoproteomic 544

data analysis package (Kim *et al.* 2021 *Cell Reports*). Each individual point (**B**) or line (**C**) represents a unique biological sample, and samples are color-coded by exercise intensity and timepoint. Overall, 19% of the total variance in the overall phosphoproteomic dataset was explained by principal component (PC)1, while PC2 explained 6% of the variance. The total number of phosphopeptides and phosphosites identified and quantified using MS are shown (**D**), in addition to the number of differentially regulated phosphosites (-/+ 1.5-fold change and adjusted P < 0.05) from each timepoint and/or exercise intensity comparison (**E**).

552

# 553 Figure 3. Human skeletal muscle phosphorylation sites differentially regulated by an acute bout of

554 work- and duration-matched HIIT and/or MICT. Volcano plots showing the median phosphopeptide

 $\log_2$  fold change (x-axis) are plotted against the  $-\log_{10} P$  value (y-axis) for each individual exercise

intensity versus the respective timepoint (A-F). From the ~15,000 total phosphopeptides detected,

significantly up-regulated (red dots) and down-regulated (blue dots) phosphosites are shown (-/+ 1.5-fold

change and adjusted P < 0.05), with black dots representing phosphosites that were detected but not

significantly regulated by exercise. Volcano plots comparing signaling responses to each exercise

560 intensity (i.e., HIIT versus MICT) at each timepoint are shown in **G-H**.

561

562

# 563 regulated by HIIT and/or MICT. Kinase activity (A) was inferred via direction analysis using kinase perturbation analysis (KinasePA; (Yang et al., 2016)) to annotate and visualize how kinases and their 564 565 known substrates are perturbed by each exercise intensity and timepoint. Pathway enrichment analysis (B) 566 was performed using the Reactome database (Joshi-Tope et al., 2005) to determine biological pathways that are enriched within the lists of significantly regulated genes (corresponding to their respective 567 568 phosphoproteins) for each exercise intensity and timepoint relative to its respective pre-exercise control. For kinase activity inference (A) and pathway enrichment (B), z-scores above and below the dotted lines 569 (corresponding to |z| score |> 1.6) were considered as increased or decreased by exercise, respectively. 570

Figure 4. Kinase and pathway enrichment uncovers common and unique kinases and pathways

572	Figure 5. Kinase-substrate predictions and pathway enrichment analysis identify differential
573	regulation of downstream substrates and pathways in response to HIIT versus MICT. Kinase-
574	substrate associations were predicted in response to HIIT and MICT via the phosphoproteome signaling
575	profiles and kinase recognition motif of known substrates using PhosR (Kim et al., 2021a). This analysis
576	generated predictions matrices, with columns corresponding to kinases, rows corresponding to
577	phosphosites, and values in the heat maps denoting how likely a phosphosite is phosphorylated by a given
578	kinase in response to HIIT (A) and MICT (B). Pathway enrichment analysis was performed using kinase-
579	substrate predictions (i.e., phosphosites with a high prediction score for each kinase) to determine how
580	kinases regulate common and/or distinct signaling pathways in response to HIIT (C) and MICT (D).
581	
582	Figure 6. Signalome network highlights distinct HIIT and MICT kinase clusters and differential
583	signaling trajectories in response to each exercise intensity. Signalome networks for HIIT (A) and
584	MICT (B) exercise were constructed using the PhosR phosphoproteomic data analysis package (Kim et
585	al., 2021a). This 'signalome' construction method utilized the phosphoproteome signaling profile and
586	kinase recognition motif of known substrates to visualize the interaction of kinases and their collective
587	actions on signal transduction. Kinases clustered together are highly correlated in terms of kinase-
588	substrate predictions. Visualization of five phosphoprotein clusters from the phosphoproteomic dataset
589	highlights distinct kinase-substrate regulation within the HIIT and MICT signaling networks, with shared
590	and unique signaling trajectories shown for a panel of kinases in response to HIIT (C) and MICT (D).
591	
592	Figure 7. Correlation of HIIT and MICT phosphosites and plasma lactate levels identifies > 3,000
593	lactate-correlated sites including functional phosphosites that govern protein activity and metabolic
594	regulation. Spearman correlation of individual phosphorylation sites (n=8,509 total) with plasma lactate
595	concentrations at each timepoint and exercise intensity (n=60 total plasma samples analyzed) are shown
596	for four of the most significantly correlated sites ( $q < 0.05$ with Benjamini Hochberg FDR) with

solution annotated functional roles in governing their respective phosphoprotein's activation state and regulating a

range of key metabolic processes (e.g., glycolysis, glucose transport and mitochondrial biogenesis)

599 including PDHA1 S201 (A), RPTOR S859 (B), TFEB S123/S128/S136 (C) and TBC1D4 S588 (D).

600

### 601 METHODS

## 602 **Ethical approval**

603 This study was approved by the Australian Catholic University Human Research Ethics Committee

604 (approval number 2017-311H), prospectively registered with the Australian New Zealand Clinical Trials

605 Registry (registration number ACTRN12619000819123) and conformed to the standards set by the

606 Declaration of Helsinki. All participants completed medical history screening to ensure they were free

from illness and injury and were informed of all experimental procedures and possible risks associated

608 with this study prior to providing their informed consent.

609

# 610 Human participants

Ten healthy males aged 18-30 yr with a body mass index  $18.5 - 27.0 \text{ kg/m}^2$  were recruited to participate 611 612 in this study. Participant characteristics are shown in Figure 1B. Inclusion criteria were physical 613 inactivity (i.e., inactive in terms of exercise training and job; < 150 min/wk moderate-intensity exercise; 614 no structured physical activity for six months prior to recruitment), no cardiopulmonary abnormalities, no 615 injuries, ability to pass the Exercise and Sport Science Australia (ESSA) pre-exercise screening tool and/or obtain general practitioner clearance to exercise, and ability to ride a stationary cycle at high 616 617 intensity. Exclusion criteria were known cardiovascular disease or diabetes mellitus, major or chronic illness that impairs mobility and/or eating/digestion, taking prescription medications (i.e., beta-blockers, 618 anti-arrhythmic drugs, statins, insulin sensitizing drugs, or drugs that increase the risk of bleeding 619 620 [anticoagulants, antiplatelets, novel oral anticoagulants, nonsteroidal anti-inflammatory drugs, selective 621 norepinephrine reuptake inhibitors, or selective serotonin reuptake inhibitors], or known bleeding disorder

- 622 (i.e., hemophilia A [factor VIII deficiency], von Willebrand disease, or other rare factor deficiencies
- 623 including I, II, V, VII, X, XI, XII and XIII).
- 624

# 625 Participant baseline measurements, exercise testing and familiarization

626 Participants arrived at the laboratory following a 10-12 h overnight fast for dual-energy X-ray

627 absorptiometry (DXA)-based body composition analysis (Lunar iDXA; GE HealthCare, Chicago, IL,

628 USA). Upon arrival each participant's height and body mass were recorded, bladder was voided and any

629 metal jewelry or clothing items containing metal were removed prior to DXA scanning. Next, resting

630 metabolic rate (RMR) testing was performed using a calibrated TrueOne 2400 (Parvo Medics, Sandy, UT,

631 USA) with expired air collected for a total of 25 min, including 10 min baseline measurement and 15 min

632 data collection. Following RMR, resting blood pressure and heart rate were recorded in a seated position.

Following baseline measurements, each participant completed an incremental test to volitionalfatigue on an electronically braked cycle ergometer (Lode Excalibur Sport; Lode, Groningen,

635 Netherlands) to determine  $\dot{V}O_2$  peak and PPO. During the maximal exercise capacity test expired gas was

636 collected every 30 s via open-circuit respirometry (TrueOne 2400; Parvo Medics) with continuous heart

637 rate monitoring (Polar Heart Rate Monitor; Polar Electro, Kempele, Finland). Before each test, gas

analyzers were calibrated with commercially available gases (16% O<sub>2</sub>, 4% CO<sub>2</sub>), and volume flow was

639 calibrated using a 3L syringe. Following a 5-min warm up at 1 W/kg, resistance was increased by 25 W

640 every 150 s until volitional fatigue, determined as the inability to maintain a cadence > 60 rpm. Individual

641  $\dot{VO}_2$  peak and PPO were determined, with PPO calculated as Wfinal + (t/150 \* 25) if the final stage was

not completed, to calculate the work rate for subsequent work ( $67.9 \pm 10.2 \text{ kJ}$ ) and duration (10 min)

643 matched HIIT and MICT exercise trials. At least 72 h prior to the first randomized exercise trial,

644 participants returned to the laboratory for exercise trial familiarization. Following a 5-min warmup at 1

645 W/kg, participants completed two cycling-based exercise sessions consisting of a single bout of HIIT and

646 MICT (10 min total each) to confirm their ability to successfully complete exercise trials at the prescribed

647 intensities.

### 648

# 649 Dietary control and standardized meals

650 Participants recorded dietary information using the Easy Diet Diary mobile phone application. Food and 651 fluid intake for all meals and snacks was recorded over a three-day period and analyzed by an accredited 652 research dietician. The habitual diet record and baseline DXA/RMR data were used to prescribe a 653 standardized meal, which was provided with cooking instructions and consumed at the participant's home 654 for dinner between 1800-2000 h before each trial day. The macronutrient composition of the standardized 655 dinner was 50% carbohydrate, 30% fat and 20% protein. Participants refrained from consuming any other food or fluids other than water from 2000 h the evening prior to each trial. Participants also refrained 656 from caffeine consumption after 1200 h and alcohol consumption and ibuprofen 24 h prior to each trial. 657

658

## 659 Exercise trials and skeletal muscle biopsy collection

660 In a randomized crossover design, participants were assigned their first exercise trial (i.e., HIIT or MICT, 661 with half of participants randomly assigned to perform the HIIT session first) prior to commencing trial 662 days and did not perform any exercise in the 72 h prior to each trial day. The HIIT session consisted of 10 663 min total cycling with 1-min intervals at  $85 \pm 0.1\%$  of individual PPO ( $176 \pm 34$  W) interspersed with 1min active recovery intervals at 50 W. The MICT protocol was work- and duration-matched and consisted 664 of an acute bout of continuous cycling at  $55 \pm 2\%$  of individual PPO (113 ± 17 W). A schematic of the 665 666 overall study design is shown in **Figure 1A**. The two HIIT and MICT exercise trials were separated by > 10 days, and it was not possible to blind participants nor the principal researchers to the order of these 667 668 trials.

669 On trial days participants arrived at the laboratory at 0700-0800 h, having fasted overnight since 670 consuming the standardized dinner the evening prior, and only consumed water during the trials. Each 671 participant's preferred arm was cannulated for blood collections (detailed below) and local anesthetic (1% 672 lignocaine hydrochloride in saline; McFarlane; Surrey Hills, Victoria Australia; 11037-AS) was 673 administered to the vastus lateralis by a highly experienced medical doctor. A percutaneous skeletal

674 muscle biopsy was collected at rest prior to commencing exercise (0 min) using a Bergstrom needle modified with suction and immediately snap-frozen, placed in liquid nitrogen and stored at -80 °C until 675 676 analysis. Additional skeletal muscle biopsy samples were collected from each participant mid-exercise (5 min) and immediately post-exercise (10 min), with the total 10 min cycling duration consistent for each 677 678 exercise intensity. For the HIIT trial, the mid-exercise biopsy was collected during an active recovery 679 interval on a bed placed directly behind the cycle ergometer (~30 sec), and participants re-commenced 680 cycling immediately after the biopsy was collected. For the MICT trial, participants stopped cycling (~30 681 sec) for the mid-exercise biopsy collection and re-commenced cycling immediately after the biopsy was collected. 682

683

#### **Blood sampling and analyses** 684

685 Upon arrival to the laboratory, a cannula (22 G; Terumo, Tokyo, Japan) was inserted into an antecubital 686 vein of each participant. Two vacutainers of venous blood (6 mL each) were collected via cannula at the 687 same timepoints as skeletal muscle biopsies above, including pre-exercise (0 min), mid-exercise (5 min) 688 and immediately post-exercise (10 min). Lipid panels (Roche Diagnostics, Basel, Switzerland; 689 6380115190) including triglyceride, total cholesterol, high-density lipoproteins (HDL) and low-density 690 lipoproteins (LDL) were immediately measured from an aliquot of whole blood (~19  $\mu$ L) using the 691 COBAS b 101 system (Roche Diagnostics). Following inversion ten times, one EDTA-coated vacutainer 692 collected for plasma (Interpath, Somerton, Victoria, Australia; 454036) was immediately placed on ice, 693 centrifuged at 1,500 x g for 10 min at 4 °C, aliquoted and stored at -80 °C until analysis. Simultaneous 694 measurement of glucose and lactate from plasma aliquots was performed in duplicate using a calibrated 695 YSI 2900 Biochemistry Analyzer (YSI Incorporated, Yellow Springs, OH, USA). 696

#### 697 Phosphoproteomic sample preparation

As depicted in Figure 2A and detailed below, proteins from each human skeletal muscle biopsy sample 698

were extracted, digested to peptides with trypsin, and isobarically labeled prior to phosphopeptide 699

700 enrichment, fractionation and analysis by LC-MS/MS. Briefly, ~30 mg of each snap-frozen human 701 skeletal muscle was lysed as previously described (Blazev et al., 2022) in 6 M guanidine HCL (Sigma, St. 702 Louis, MO, USA; G4505) and 100 mM Tris pH 8.5 containing 10 mM tris(2-carboxyethyl)phosphine 703 (Sigma; 75259) and 40 mM 2-chloroacetamide (Sigma; 22790) using tip-probe sonication. The resulting 704 lysate was heated at 95 °C for 5 min and centrifuged at 20,000 x g for 10 min at 4 °C, and the resulting 705 supernatant was diluted 1:1 with water and precipitated with 5 volumes of acetone at -20 °C overnight. 706 Lysate was then centrifuged at 4,000 x g for 5 min at 4 °C and the protein pellet was resuspended in 707 Digestion Buffer (10% 2,2,2-Trifluoroethanol (Sigma; 96924) in 100 mM HEPES pH 8.5). Protein 708 content was determined using BCA (Thermo Fisher Scientific, Waltham, MA, USA). Four hundred µg 709 protein (normalized to 100 µL final volume in Digestion Buffer) was digested with sequencing grade 710 trypsin (Sigma; T6567) and LysC (Wako Chemicals, Richmond, VA, USA; 129-02541) at a 1:50 711 enzyme:substrate ratio at 37 °C overnight with shaking at 2,000 rpm. 712 Digested peptides were labeled with 800 µg of 10-plex tandem mass tags (TMT) in 50% 713 acetonitrile to a final volume of 200 µL at room temperature for 1.5 h. The TMT reaction was deacylated 714 with 0.3% (w/v) of hydroxylamine for 10 min at room temperature and quenched to final volume of 1% 715 trifluoroacetic acid (TFA). Each experiment consisting of 7 TMT labeled peptides (10 total experiments, 716 each including all 6 timepoints from a single participant's HIIT and MICT trials and a pooled internal 717 reference mix of peptides consisting of peptides from all 10 participants) was then pooled, resulting in a 718 final amount of 4 mg peptide per TMT 10-plex experiment. The sample identity and labeling channels are 719 uploaded as a table with the raw proteomic data to the ProteomeXchange Consortium via the PRIDE 720 partner repository (see Resource Availability for login details). 721 Twenty µg of TMT-labeled peptide was removed for total proteome analysis (data not shown, as 722 only 5-10 min of exercise does not affect total muscle protein content), and phosphopeptides were 723 enriched from the remaining digestion of pooled peptides from each experiment using a modified version 724 of the EasyPhos protocol (Humphrey et al., 2018). Briefly, samples were diluted to a final concentration of 50% isopropanol containing 5% TFA and 0.8 mM KH<sub>2</sub>PO<sub>4</sub>. Dilutions were then incubated with 15 mg 725

of TiO<sub>2</sub> beads (GL Sciences, Tokyo, Japan; 5010-21315) for 8 min at 40 °C with shaking at 2,000 rpm.

- 727 Beads were washed four times with 60% isopropanol containing 5% TFA and resuspended in 60%
- isopropanol containing 0.1% TFA. The bead slurry was transferred to in-house packed C8 microcolumns
- (3M Empore; 11913614) and phosphopeptides were eluted with 40% acetonitrile containing 5%
- ammonium hydroxide. The enriched phosphopeptides and 20 µg aliquot for total proteome analysis were
- acidified to a final concentration of 1% TFA in 90% isopropanol and purified by in-house packed SDB-
- 732 RPS (Sigma; 66886-U) microcolumns. The purified peptides and phosphopeptides were resuspended in
- 733 2% acetonitrile in 0.1% TFA and stored at -80 °C prior to offline fractionation using neutral phase
- 734 C18BEH HPLC as previously described (Blazev et al., 2022).
- 735

# 736 LC-MS/MS data acquisition and processing

737 Peptides were analyzed on a Dionex 3500 nanoHPLC, coupled to an Orbitrap Eclipse mass spectrometer 738 (Thermo Fisher Scientific) via electrospray ionization in positive mode with 1.9 kV at 275 °C and RF set 739 to 30%. Separation was achieved on a 50 cm x 75 µm column (PepSep, Marslev, Denmark) packed with 740 C18-AQ (1.9 µm; Dr Maisch, Ammerbuch, Germany) over 120 min at a flow rate of 300 nL/min. The 741 peptides were eluted over a linear gradient of 3-40% Buffer B (Buffer A: 0.1% formic acid; Buffer B: 80% acetonitrile, 0.1% v/v FA) and the column was maintained at 50 °C. The instrument was operated in 742 743 data-dependent acquisition (DDA) mode with an MS1 spectrum acquired over the mass range 350-1,550 m/z (120,000 resolution, 1 x 10<sup>6</sup> automatic gain control (AGC) and 50 ms maximum injection time) 744 followed by MS/MS analysis with fixed cycle time of 3 s via HCD fragmentation mode and detection in 745 the orbitrap (50,000 resolution,  $1 \times 10^5$  AGC, 150 ms maximum injection time, and 0.7 m/z isolation 746 width). Only ions with charge state 2-7 triggered MS/MS with peptide monoisotopic precursor selection 747 and dynamic exclusion enabled for 30 s at 10 ppm. 748 749 DDA data were searched against the UniProt human database (June 2020; UP000005640 9606

- and UP000005640\_9606\_additional) with MaxQuant v1.6.7.0 using default parameters with peptide
- r51 spectral matches, peptide and protein FDR set to 1% (Cox and Mann, 2008). All data were searched with

752 oxidation of methionine set as a variable modification and cysteine carbamidomethylation set as a fixed modification. For analysis of phosphopeptides, phosphorylation of Serine, Threonine and Tyrosine was 753 set as a variable modification, and for analysis of TMT-labeled peptides, TMT was added as a fixed 754 modification to peptide N-termini and Lysine. First search MS1 mass tolerance was set to 20 ppm 755 756 followed by recalibration and main search MS1 tolerance set to 4.5 ppm, while MS/MS mass tolerance 757 was set to 20 ppm. MaxQuant output data were initially processed with Perseus (Tyanova et al., 2016) to 758 remove decoy data, potential contaminants and proteins only identified with a single peptide containing 759 oxidized methionine. The 'Expand Site' function was additionally used for phosphoproteomic data to 760 account for multi-phosphorylated peptides prior to statistical analysis.

761

# 762 **Bioinformatic analysis**

763 For analysis of human muscle phosphopeptides with TMT-based quantification, data were first log<sub>2</sub> 764 transformed and each phosphosite abundance was corrected by subtracting the abundance of the pooled 765 sample in the same TMT batch. The phosphoproteomic data were processed using the pipeline implemented in the PhosR package (Kim et al., 2021a). Filtering was performed to retain phosphosites 766 767 present in at least three participants (out of ten total participants), in at least one timepoint (out of six total 768 timepoints). Missing values in the retained phosphosites were imputed first by a site- and sample 769 condition-specific imputation method, where for a phosphosite that contains missing values in a 770 condition, if more than three samples were quantified in that condition, the missing values were imputed 771 based on these quantified values for that phosphosite in that condition, and then by a random-tail 772 imputation method (Kim et al., 2021b). The imputed data were normalized using 'Combat' function in sva package (Johnson et al., 2007) for removing batch effects and then 'RUVphospho' function in PhosR 773 for the removal of additional unwanted variation with a set of stably phosphorylated sites as negative 774 775 controls (Xiao et al., 2022). The batch-corrected data were further converted to ratios relative to the pre-776 exercise samples (i.e., '0 min' controls).

777	Differentially phosphorylated sites were identified using limma R package (Ritchie et al., 2015).	
778	Phosphosites with -/+ 1.5-fold change and FDR-adjusted $P$ value < 0.05 were considered as differentially	
779	phosphorylated (Figure 3A-H). Kinase activities at post- or mid-exercise for both HIIT and MICT were	
780	inferred based on the changes in phosphorylation (relative to the corresponding pre-exercise control	
781	samples) of their known substrates using the KinasePA package (Yang et al., 2016) and the	
782	PhosphoSitePlus annotation database (Hornbeck et al., 2012) (Figure 4A). Pathway enrichment analysis	
783	was then performed, whereby phosphosites were first summarised into their host protein levels by taking	
784	the maximum log <sub>2</sub> fold change for each comparison between conditions, and then the pathway enrichment	
785	was performed based on the inferred host protein changes using the KinasePA package and Reactome	
786	database (Joshi-Tope et al., 2005) (Figure 4B).	
787	Putative substrates of kinases for HIIT and MICT were predicted using the	
788	'kinaseSubstrateScore' function in the PhosR package, and the results were represented as heatmaps	
789	(Figure 5A-B). Pathway over-representation analysis was performed on protein sets identified from the	
790	kinase-substrate scoring analysis (i.e., kinase-substrate pairs with score $> 0.85$ were selected) per kinase	
791	using the 'enrichKEGG' function implemented in the clusterProfiler R package (Yu et al., 2012), and P	
792	values were adjusted for multiple testing using Benjamini Hochberg FDR correction at $\alpha = 0.05$ (Figure	
793	5C-D). The prediction scores were subsequently used for constructing signalome networks. Pearson's	
794	correlation was performed on pairwise kinases, and then the correlation matrix was binarized based on the	
795	correlation score threshold of 0.85. Undirected graphs were built from the binary adjacency matrix using	
796	the 'graph_from_adjacency_matrix' function from the igraph package (Csárdi G, 2024), and results from	
797	this analysis were presented as network diagrams (Figure 6A-B).	
798	Five protein modules were identified by clustering proteins with phosphosites sharing similar	
799	dynamic phosphorylation profiles and kinase regulation across both HIIT and MICT. The proportion of	
800	phosphosites that were phosphorylated by kinases for each protein module was calculated and presented	
801	as bubble plots (Figure 6C-D). The activity of each protein module was then inferred. The regulated	
802	phosphosites were first obtained across all conditions (i.e., ANOVA test with adjusted $P < 0.05$ ), and the	

- average  $\log_2$  fold change of the regulated phosphosites for each of the five modules (relative to the
- 804 corresponding pre-exercise control) were calculated (Supplemental Figure 1A-E).
- 805

# 806 Statistical analysis

- 807 Statistical analysis of plasma lactate and glucose concentrations was performed using GraphPad Prism
- 808 (version 9.4). A two-way ANOVA with repeated measurements was used to determine the effects of time
- and exercise intensity, with Tukey's test applied for multiple comparisons (P < 0.05 considered as
- significant; sample size and statistical parameters reported in the **Figure 1** legend). Spearman correlation
- 811 of individual phosphorylation sites with plasma lactate concentrations at each timepoint and exercise
- 812 intensity was performed to determine significantly correlated phosphosites, with Benjamini Hochberg
- false discovery rate applied (q < 0.05 considered as significant; sample size and statistical parameters
- 814 reported in the **Figure 7** legend).
- 815

С

Main Effect of Time: \*\*\*\* P < 0.0001

Main Effect of HIIT vs. MICT: \* P < 0.05

Participant Characteristic	Mean ± Standard Deviation
Number of participants	10 (males)
Age (years)	25.4 ± 3.2
Height (cm)	176.7 ± 7.2
Body mass (kg)	75.7 ± 8.7
Body mass index (BMI; kg/m²)	23.5 ± 1.6
Fat mass (kg)	15.0 ± 4.2
Lean mass (kg)	57.6 ± 7.3
Resting metabolic rate (kcal/d)	1770.1 ± 185.7
Absolute VO₂peak (L/min)	2.8 ± 0.4
Relative VO <sub>2</sub> peak (mL/kg/min)	37.9 ± 5.2
Peak power output (W)	208 ± 40
Resting heart rate (beats per minute)	61.6 ± 5.0
Systolic blood pressure (mmHg)	121.1 ± 12.8
Diastolic blood pressure (mmHg)	76.6 ± 9.9
Triglycerides (whole blood; mmol/L)	1.5 ± 1.1
Total cholesterol (whole blood; mmol/L)	3.8 ± 0.6
LDL cholesterol (whole blood; mmol/L)	2.1 ± 0.5
HDL cholesterol (whole blood; mmol/L)	1.2 ± 0.2
