12 **Abstract**

13 Violence against women and children (VAWC) is a significant health and human rights issue
14 closely tied to multiple Sustainable Development Goals. While VAWC is prevalent in all
15 countries, the severity and incidence of VAWC increase during wars, natural disasters,
16 economic crises, and pandemics, all of which have affected Yemen in recent years. This

17 systematic review synthesizes evidence from qualitative and quantitative studies on the types,
18 prevalence, perpetrators of, and risk factors for VAWC in Yemen. Before initiating the search,
19 the protocol and search strategy were registered to PROSPERO (CRD42021237855). We
20 systematically searched four biomedical databases and grey literature sources and used reverse
21 snowball sampling to identify eligible studies. The 31 studies included in the analysis depicted a
22 range of forms of VAWC, encompassing honor violence, female genital mutilation and cutting,
23 early and very early marriage, tourist marriage, family and intimate partner violence, and
24 gender inequities in access to food, education, and medical care. Included studies reported a high
25 prevalence of many forms of violence, including corporal punishment in schools and intimate partner
26 violence. We reviewed study quality and how studies addressed ethical concerns in VAWC-related
27 research. We found that several studies did not report ethics review or interviewer training and no
28 studies discussed safety planning or addressing the mental health needs of participants in VAWC
29 research. This systematic review provides a much-needed synthesis of existing research on
30 VAWC in Yemen. Since the start of the 2014 war, Yemen has become the world's largest
31 humanitarian crisis, with the highest rate of maternal mortality and gender inequality in the
32 world. We only identified one study initiated after the recent war in Yemen. This deficiency
33 represents a missed opportunity to understand how the ongoing war has reversed prior gains in
34 reducing the prevalence of child and very early child marriage and introduced new forms of
35 gender-based violence, including tourist marriage.

40 **Introduction**

41 Violence against women and children (VAWC) is a global human rights issue that closely
42 relates to the achievement of the Sustainable Development Goals (SDGs), particularly
43 Goal 5, which aims to achieve gender equality and empower all women and girls and
44 Goal 16, which seeks to promote peaceful and inclusive societies for sustainable
45 development, provide access to justice for all, and build effective, accountable
46 institutions. In this systematic review (SR), we summarize primary and secondary
47 research related to the forms, perpetrators, consequences, and reporting of VAWC in
48 Yemen to inform future research and the development of interventions that prevent
49 VAWC in Yemen or address the consequences of VAWC.

50 **Humanitarian crisis**

51 In 2023, eighty percent of Yemen's population of 29.8 million people required
52 humanitarian assistance [1], and 4.5 million people were internally displaced [2], making
53 Yemen the world's largest humanitarian crisis. The recent war has decimated the
54 country's economy, healthcare, education, and infrastructure [3]. In addition to the
55 ongoing humanitarian crisis, Yemen has deeply entrenched gender inequities where
56 limited resources mean that women and girls do not have the same access to limited
57 educational, health care, or food resources as their male counterparts [4,5]. As in any

58 humanitarian crisis [6], the prolonged war disproportionately affected Yemeni women
59 and children.

60 Non-governmental organizations (NGOs) in Yemen report increased levels of forced,
61 early marriage and trafficking of girls and young children in response to the ongoing war
62 [7]. Girls are sexually exploited in bars and restaurants in the larger towns of Yemen and
63 may be forced to traffic illegal drugs [8]. Both Saudi and Houthi forces have used child
64 soldiers [9]. The economic crisis and targeted attacks on infrastructure, including
65 education, health care, and government services, mean that child labor has become
66 commonplace [8], affecting mental and physical health (19). Where school bombings
67 have not occurred, parents are reluctant to send their children to school for fear of
68 bombing, trafficking, recruitment of child soldiers, and other forms of community or
69 war-related violence [10].

70 **Violence against women**

71 Intimate partner violence (IPV), defined as “behavior by an intimate partner or ex-
72 partner that leads to physical, sexual or psychological harm, including aggression, sexual
73 coercion, psychological abuse, and controlling behaviors” [11], is the most prevalent
74 form of gender-based violence (GBV) globally. Longstanding gender inequities codified
75 into law mean that Yemeni women, their families, and their community may perceive
76 their experience of IPV, including marital rape, as their fault [12]. Societal stigma
77 associated with physical and sexual violence means that women and children have
78 limited options for support or for reporting violence. Where support is available, the

79 stigmatization of women or children who experience violence, especially sexual
80 violence, prevents reporting or accessing available services [13].

81 **Violence against children**

82 The World Health Organization (WHO) defines violence against children (VAC) as
83 “violence in all forms experienced by children who are under 18 years old, perpetrated
84 by parents or other caregivers, peers, romantic partners, or strangers” [14,15]. Globally,
85 75% of children experience physical or emotional abuse from their parents, peers, or
86 caretakers [14,15]. Female genital mutilation or cutting (FGM/C), defined as “all
87 procedures involving partial or total removal of the external female genitalia or other
88 intentional injuries to the female genital organs for non-medical reasons,” [16] is a
89 prevalent cultural practice in Yemen and elsewhere in the Middle East and North Africa
90 (MENA) and sub-Saharan Africa (SSA) [17]. The practice of FGM/C leads to an increase in
91 urinary, vaginal, and pregnancy-related morbidities and mortalities, repeat surgeries,
92 and death [12].

93 ***Gender inequitable access to food, education, employment, health care, and legal*** 94 ***protections***

95 In 2021, Yemen ranked last out of 170 countries on the Gender Inequality Index (GII)
96 [18]. Educational attainment and literacy in Yemen are low (8, 10), especially for women
97 and only 6% of women work outside of their home [5]. Yemen has two legal systems,
98 *Shari’a* and *Kabeelee*, or tribal law. Under *Shari’a* law, Yemeni women lack child custody

99 protections and have limited to no right to divorce, property rights, or the right to
100 manage their finances [19]. In contrast, men are legally entitled to control their spouse's
101 money and property, are the default recipients of child custody, and can divorce their
102 wives by saying "talaq" [19]. Marital rape remains non-criminalized [20] even though
103 Yemen acceded to the Convention on the Elimination of All Forms of Discrimination
104 Against Women (CEDAW) in 1984, mandating states to ensure that marriage is founded
105 on free and full consent [21]. Yemen does not have a minimum age of marriage, even
106 though Yemen ratified the Convention on the Rights of the Child in 1989, setting 18 as
107 the minimum age for marriage.

108 ***Intersectionality and violence against women and children***

109 Minority ethnic groups in Yemen, including the indigenous *Akhdam* or *Muhamasheen*
110 community and refugees from Somalia, Sudan, or Ethiopia, face high levels of
111 discrimination and violence in Yemen, including sexual assault and rape [22].
112 Homosexuality in Yemen is a criminal offence under *Shari'a* law that is punishable by
113 death, which means that violence against lesbian, gay, bisexual, transgender, queer, and
114 intersex (LGBTQI) likely goes unreported [22].

115 **Materials and Methods**

116 We used a mixed-methods SR design with a narrative synthesis approach to provide a
117 broad overview of VAWC that could be used to inform policymakers and develop
118 research priorities [23]. The SR protocol was developed using the 2015 Preferred

119 Reporting Items for Systematic Reviews and Meta-Analyses Protocols (PRISMA-P)
120 guidelines [24] and registered on the PROSPERO Register of Systematic Reviews before
121 initiating the search (CRD42021237855). We followed the 2020 PRISMA guidelines for
122 conducting and reporting systematic reviews [25] and reported the PRISMA elements in
123 Supplementary Table S1.

124 **Search strategy**

125 We conducted a systematic search of four electronic databases, Ovid (MEDLINE) and
126 (Embase), Cumulated Index to Nursing and Allied Health Literature (CINAHL), and Web
127 of Science (WoS), using a combination of MeSH and text terms (S2 Table). We ran the
128 searches on 18 February 2021 and did not include language or date restrictions. We
129 updated the search for Ovid (Medline), WoS, and CINAHL on 8 April 2024 but no longer
130 had access to Ovid (Embase) and did not rerun that search. We also searched for
131 additional citations using backward snowball sampling [26], reviewing the citations in
132 included studies. Additional studies were identified through grey literature searches,
133 using the Google search engine and reviewing NGO websites, including the United
134 Nations High Commissioner for Refugees (UNHCR), Save the Children, United Nations
135 Children's Fund (UNICEF), and United Nations Family Planning Association (UNFPA)
136 websites. We also reviewed Yemen country reports from the Demographic and Health
137 Surveys (DHS) and the Multi-Cluster Indicator Surveys (MICS), population-representative
138 survey research initiatives that focus on maternal and child health (MCH)-related
139 outcomes.

140 ***Inclusion criteria***

141 Included studies were primary research studies that used any design and that reported
142 on any form of sexual, physical, emotional, or economic violence against Yemeni women
143 and children, including IPV and family violence (early or very early marriage or forced
144 marriage, femicide, prenatal sex selection, female infanticide, FGM/C, gendered access
145 to food, education, vaccines, healthcare, employment; dowry-related violence; honor
146 killings; child labor; child neglect and maltreatment) workplace violence; war-related
147 violence (child soldiers, captivity, trafficking of women and children, war-related sexual
148 violence, physical attacks on women and children (e.g., rape, bombing), indirect attacks
149 (bombing of water treatment facilities, hospitals, schools); pandemic-related violence
150 (child labor, increased family, or IPV), violence related to displacement, gendered access
151 to masks or COVID-19 treatments or vaccines. Studies that did not report on VAWC in
152 Yemen and publications that did not represent primary research or secondary analyses
153 of participant-level data (e.g., commentaries, systematic reviews, editorials) were
154 excluded.

155 **Data extraction and management**

156 Citations were exported to EndNote (version 9.3.3) for deduplication using the Braner
157 approach [27]. Citations were then exported to Covidence version 2.0 [28] for title-
158 abstract and full-text screening and data extraction using a pre-piloted data extraction
159 form (Supplementary Text 5). Three reviewers (SC, MAL, SS) independently conducted
160 the screening and data extraction. A fourth reviewer (LM) resolved disagreements. A

161 meta-analysis was not possible due to the heterogeneity of study designs, types of
162 violence, and age groups. We used thematic synthesis [29] to summarize findings across
163 studies. We treated different types of violence as themes and identified additional
164 themes, including risk factors, perpetrators, resources, and barriers to accessing
165 resources, from the included studies and our review of related literature.

166 **Quality assessment**

167 We assessed the quality of included primary research studies using the Mixed Method
168 Analysis Tool (MMAT), version 2018 [30], which reviews the study's design, sampling
169 strategy, generalizability, data collection methods, integrity of intervention (where
170 applicable), and analytic approach. We did not review the quality of population-level
171 surveys (e.g., MICS, DHS, Arab Family Survey), which are generally regarded as high
172 quality. Quality assessment criteria were applied by two independent reviewers (SS,
173 MN); disagreements were resolved through a third reviewer (LM).

174 **Results**

175 The screening process is summarized in the PRISMA Flow diagram [25] shown in Figure
176 1. From the initial search of the database conducted in February 2021, we identified 459
177 abstracts, while in the updated search done in April 2024, 106 abstracts were identified.
178 After removing duplicates, 356 titles and abstracts (291 from the initial search and 65
179 from the updated search) were reviewed in Covidence. Subsequently, 63 studies were
180 assessed for full-text eligibility, with 32 studies excluded for being systematic reviews,

181 commentaries, editorials, or other non-primary research (19 studies) or for not
182 measuring violence or stigma against Yemeni women and children (13 studies). Data
183 was extracted from the 31 studies (6 reports and 25 articles(2 of which are grey
184 literature sources)) that met the inclusion criteria. For details on the reasons for
185 exclusion at the full-text review stage, refer to Supplementary Table S3.

186 **Overview of included studies**

187 Table 1 provides an overview of the types of violence, risk factors, and consequences
188 examined in the included studies, excluding data from the Yemen DHS and MICS reports
189 (n=4) as they were included in other studies in the table. We identified 17 primary
190 research studies, six reports, and eight secondary analyses that met the study inclusion
191 criteria. Studies and reports included a diversity of age groups and types of violence and
192 covered all of Yemen's 22 governorates. Primary research included four qualitative
193 studies and two qualitative components of mixed-method studies [7,21,31–34]. Most
194 qualitative studies conducted in-depth interviews (IDIs; N=3), one study used a focus
195 group discussion (FGD) approach [21], and two studies analyzed answers to open-ended
196 questions in a cross-sectional questionnaire [32,34]. Supplementary Table S4 provides a
197 detailed overview of quantitative studies and the quantitative estimates in mixed
198 studies, including types of violence, measurement approach, point estimates (e.g.,
199 prevalence), measures of uncertainty (if any), associated risk factors, and regional
200 differences. All 20 quantitative studies employed a cross-sectional design. Four
201 quantitative studies [16,35–37] used DHS data [12,38,39]. Two studies [36,40] used data

202 from MICSs [41], and five studies used data from various national and sub-national
203 household surveys conducted in Yemen [42–46].

204

205 Studies included different types of VAWC, offenders or perpetrators of violence,
206 location of violence, risk factors, consequences of violence, and information on ethical
207 concerns, access to services, or safety planning. We identified two studies related to
208 early child marriage [7,21], seven studies on child abuse or maltreatment [21,40,47–51],
209 five studies on FGM/C [16,36,43,44,46], seven studies on gender differences in
210 education or health care services [35,37,42,45,52–54], and one study on community
211 violence [31], IPV [32], attitudes towards honor violence [21], GBV [33], gender
212 preference [37], dentist’s reports of suspected violence [55], and stigmatizing attitudes
213 towards women with human immunodeficiency virus (HIV) [56]. No studies presented
214 information on pandemic or war-related VAWC.

215

216 All studies reported on risk factors and perpetrators, and most studies described
217 barriers to reporting violence [7,16,31–34,36,40,42–44,47–53,55,57]. Other than the
218 DHS and MICS, which are country-wide, studies that collected primary data were
219 conducted in Aden, Sana’a, Al Hudaydah, Taiz, Al-Mukalla, Al-Mahrah, Lahij, and
220 Hadramout governorates. Most studies included both urban and rural areas, although a
221 few studies were limited to urban (N=2) [49,54] or rural (N=1) [44] populations. In most
222 studies, verbal consent, as opposed to written consent, was obtained. This practice

223 could be attributed to concerns about participant safety in research related to VAWC or
224 to Yemen's generally low literacy level. Over half of the studies (25 of 31) were
225 conducted before the 2014 war. While most VAWC occurs within the home, three
226 articles found that women were also likely to experience GBV outside the home [32–
227 34].

228 **Types of VAWC**

229 *Family and intimate partner violence against women*

230 Neither the DHS from 1991/92, 1997, or 2013 nor the 2005/6 MICS included questions
231 on women's experience of partner or family violence. In addition to the DHS and MICS,
232 two quantitative studies examined IPV [21,32]. One 2002 study of a stratified random
233 sample of 111 ever-partnered women aged 15-55 in two areas of Sana'a found that
234 55% of women had experienced physical IPV (beatings, confinement to home, torture),
235 51% experienced threats, and 17% experienced sexual IPV [32]. Participants also
236 reported experiencing violence perpetrated by their sons, brothers, fathers, mothers,
237 and uncles [32]. Many participants reported that the violence they experienced was
238 "normal" and expected given societal norms [32]. Honor violence often occurs as a
239 punitive response to perceived sexual immodesty in young girls, including after cases
240 of sexual violence where the attribution of blame lies with the victim [21]. A 2009
241 qualitative study found that teenage girls in Yemen internalized honor violence.
242 Participants reported acceptance of harsh punishments for girls who experienced
243 sexual violence because they had 'allowed' or invited the violence [21].

244 ***Early and very early child marriage***

245 The 1991/92 DHS revealed that 31% of girls were married by the age of 15 [38], a
246 figure that decreased to 29% in the 1997 DHS [39] and further dropped to 14% in the
247 2006 MICS [41], and significantly decreased to 3% in the 2013 DHS [12]. A 2009 focus
248 group study involving 138 Yemeni girls aged 12 to 18 discovered that financially
249 insecure families felt compelled to marry off their young daughters [21].

250 “First, I got married at 11, and second, my maternal uncle married me off. He
251 found the groom through his connections, and he was 50 years old. It was a
252 marriage of avarice. My uncle got a bribe of 200,000 rials, and my father got
253 160,000 in money and 300,000 in gold (dowry)....On the day of my marriage, I
254 still had not reached puberty, and I reached puberty only in his house. He had
255 intercourse with me on the first night, and of course, I did not know what a
256 man does to a woman or how to act...my feelings on that night were horrible. I
257 thought he was going to kill me, and he took me by force. I tried to defend
258 myself that night, and I could not and then I fainted and lost consciousness and
259 recovered only in the morning, and he left me alone to get rest.” (p. 462-463,
260 [21]).

261 ***Tourist marriage***

262 Tourist marriage, a recent manifestation of child marriage, involves a temporary union
263 between a Yemeni girl and a man from a wealthy Gulf country. This phenomenon has

264 arisen in response to the ongoing humanitarian crisis in Yemen stemming from the
265 2014 war. Tourist marriages can last from one day to several months and represent a
266 temporary agreement rather than a legal marriage [7,21]. In a qualitative study
267 involving stakeholders at NGOs focused on working and helping Yemeni women and
268 children in crisis, a participant highlighted poverty as the primary factor contributing to
269 the increasing incidence of this emerging form of child marriage [7].

270 “Poverty, economic hardship, unemployment and increasing cost of living were
271 all raised as reasons for families to resort to child marriage as a coping
272 mechanism to permit them to alleviate poverty or the burdens of a large family
273 with many daughters. Girls from low-income families are more likely to marry
274 before 18” (p. 9, [7]).

275 ***Female genital mutilation and cutting***

276 Five cross-sectional studies measured FGM/C, defined as “all procedures involving
277 partial or total removal of the external female genitalia or other intentional injuries to
278 the female genital organs for non-medical reasons” [16,36,43,44,46]. Three studies
279 assessed both women’s and their husbands’ attitudes toward FGM/C [16,44,46].
280 Estimates of the prevalence of FGM/C ranged from 16% in a 2008 subnational survey
281 [44] and the 2013 DHS [12] to around 20% in the 1997 DHS [39] and the 2003 Arab
282 Family Health Survey [43] and 89% in a population-representative FGM/C-specific
283 survey in three southern Yemeni governorates [46]. Traditional birth attendants called
284 *daya, gedah, kharshofa, or qabila* conducted FGM/C at home or in the community

285 [16,44,46]. While some studies found maternal education and knowledge of the harms
286 of FGM/C was predictive of their daughter’s likelihood of experiencing FGM/C [16,44],
287 other studies did not [46].

288 ***Gender preference***

289 The 1991/92 and 1997 DHS found that 20% and 33% of ever-married women preferred
290 having a male over a female child [38,39]. In one qualitative study where 220 women
291 aged <25 to >35 in Aden, Lahij, Hadramaut, Taiz, and Al Hudaydah governorates were
292 asked about their gender preferences, respondents reported that they “pray to God”
293 for a boy and not a girl child to make their husband happy [34].

294 “I had nine daughters; my husband wants a son. I was so frightened, it’s a girl
295 that I started a fever and was shivering from fright.” (pregnant woman, aged
296 33, urban residence) (p. 7, [34])

297 “My husband is only waiting to hear the good news that the baby is a boy; he
298 never thinks of me, only the gender of the baby, and I feel very badly.” (woman
299 with three living children, aged 22, rural residence) (p. 7, [34])

300 ***Gender inequitable access to food, medical care, and education***

301 Six studies described gender inequities in access to food, medical services, or
302 education using data from qualitative studies [42,52–54], the DHS [35], the Pan Arab
303 Project for Family Health (PAPFAM) [42], and the 2016 Household Income, Expenditure
304 and Consumption Surveys (HIECS) [45]. A cross-sectional quantitative study on

305 gendered access to education with 8–15-year-olds in 20 Yemeni districts found that
306 over 30% of girls were not able or allowed to attend school, compared to 10% of boys
307 [42]. A cross-sectional, multi-country survey on gendered access to medical care,
308 found that Yemeni boys exhibited a higher likelihood of seeking or receiving hospital
309 care compared to girls (prevalence sex ratio 0.85; $p < 0.05$) [35]. A statistically
310 significant proportion of women (3.66 on a scale of 1 to 5; $p < 0.001$) reported feeling
311 guilty for accessing medical services and were less likely than their male counterparts
312 to spend money on medical care [53]. A 2005 cross-sectional study on gender and
313 literacy as determinants of care-seeking behavior found that 63% of low-literacy
314 women delayed diagnosis of tuberculosis (TB) (longer than eight weeks) compared to
315 44% of fully literate women [52]. In a 2007 study, most women (69%) reported having
316 been harmed by family members when seeking medical care within the formal health
317 system [53]. The two cross-sectional surveys mentioned above also found that women
318 must seek permission from their husbands or male family members before visiting a
319 doctor or clinic [52,53].

320 ***Child abuse or maltreatment***

321 Seven studies measured violence against children (VAC) at home or in school, including
322 emotional, physical, and sexual abuse [33,40,47–51]. The majority of the studies were
323 cross-sectional. Four studies conducted interviews with children to gather information
324 about their own experiences of abuse [21,47,48,51]. Two studies analyzed caregiver
325 (mothers, aunts, grandmothers, guardians, teachers) reports of child abuse, either

326 abuse that they had witnessed or been told about [40,50]. One study examined MICS
327 data to determine the different forms of child abuse and related risk factors [40]. A
328 high level (around 80%) of adults reported experiencing emotional abuse in their
329 childhood across studies [40,47,49–51]. The 2013 DHS reported that 42% of children
330 aged 2-14 (n=5,731) were exposed to severe physical punishment (being hit on the
331 head or face with hands or by an implement) in the month before the survey. Nearly
332 80% (n=10,774) faced some form of physical discipline in the same timeframe [12]. The
333 2006 MICS reported that 94% of children aged 2-14 (n=2,702) were ever exposed to at
334 least one form of physical or psychological abuse, and over 20% of children aged 5-14
335 (n=1,733) were engaged in child labor [41]. Three studies found a high prevalence of
336 emotional and physical abuse among school children in Sana'a and four randomly
337 selected districts of Aden [47,48,51]. A 2011 study of the different forms of child
338 abuse prevalent in Yemen found that more than 90% of children aged 2-14 ever
339 experienced emotional abuse [40], and a 2019 cross-sectional study found that 35% of
340 students aged 18-24 reported experience of sexual abuse during their childhood [49].
341 A 2008 study of a random sample of students aged 7-10 (n=1,196) and another 2019
342 study with a random sample of students from five colleges at Hadramaut University
343 (n=395) found shouting, yelling, hitting by hands, severe physical punishments, and
344 sexual abuse to be commonly experienced by children [49,50]. Close to 60% of the
345 interviewed mothers (n=119) of school-aged children living in rural areas reported
346 hitting their children with their hands to discipline them [50]. Thirty-five per cent of
347 students in one quantitative study (n=139) experienced sexual violence during

348 childhood, defined as being “spoken to in a sexual way, unwanted sexual touching,
349 forced to watch movies, take naked photos” [49]. Eighty per cent of students
350 experienced verbal sexual harassment (n=111), and 19% (n=26) were coerced into
351 watching pornographic movies [49].

352 **Perpetrators of violence**

353 Most studies reported child abuse perpetrators as parents or other family members,
354 teachers, and school principals in schools or universities [40,47–51]. FGM/C practices
355 were mainly carried out by family, traditional healers, and community members at
356 home or in health facilities [16,36,43,44]. Both partners and parents perpetrated
357 honor violence [32].

358 **Legal context**

359 Legal protections for women and children facing violence are limited. In cases of sexual
360 violence against women or girls, families might force their daughters to marry the
361 perpetrator as a means of restoring the family's honor [7,21]. Divorced women are
362 often blamed for their divorce [32]. One 2002 qualitative study found that Yemeni
363 women felt that:

364 'Women have no rights...We are second-class citizens. Nobody listens, nobody
365 cares, people think this is normal, but it is not normal' (p.343, [32]).

366 In the same study, a participant reported,

367 “I do not believe what I hear from the media about equality between man and
368 woman in our society. Our society is a men's society. Men decide what is right
369 and what is wrong, not only in the family but in the whole society. They
370 interpret the holy Qur'an in harmony with their interest. We know that our
371 religion (Islam) guarantees many rights for women, but men accept only what
372 is good for them and do not accept what is not good for them. For example, in
373 some parts of Yemen, the community does not accept women's inheritance:
374 this is against Islamic law! This is because they don't accept women as people”
375 (p.343, [32]).

376 While Yemen is considering a bill that specifies girls should be at least 18 to marry, the
377 bill has not been passed into law. In addition to country-level legal prohibitions against
378 child marriage, alternative approaches that leverage Islamic prohibitions against child
379 marriage are needed [21]. According to a workshop conducted by the Arab Resource
380 Collective (ARC), early marriages are practiced due to weak laws and the inability to
381 feed children [21]. The lack of birth or marriage registries makes it challenging to track
382 the girls' age at marriage [7,21], and the ongoing conflict has set back previous
383 progress toward reducing child marriage in Yemen.

384 “A boy and a girl can be considered adults, making it difficult for them to
385 understand that they are marrying children. We managed to include it in the
386 national dialogue, and we succeeded. But unfortunately, [child marriage] is
387 now on hold due to conflict” (p. 10, [7]).

388 In a study aiming to gather participant suggestions for mitigating child marriage,
389 recommendations included providing financial support to families for girls' education,
390 funding NGOs dedicated to addressing child marriage, raising awareness within
391 communities about girls' rights, and implementing local interventions as potential
392 strategies [7].

393 **Table 1.** Overview of included studies

Author, year of publication	Location (city), governorate, study setting	Sample	Rural or urban location	Study type	Research question or objective	Type of violence	Place violence occurs	Perpetrators	Risk factors	Consequences of violence	Barriers, tools, and strategies for reporting
Al-Khulaidi, 2013 [16]	Aden, Al Hudaydah, Sana'a, Taiz, Hadramaut, Ibb, Dhamar, Al Mahwit, Hajjah, Amran, Sa'dah, Lahij, Al Bayda, Marib, Al Jawf, Shabwah, Al Mahrah, Raymah	11,528 women aged 15-49	Both	Quantitative (secondary data analysis: Yemen DHS 1997 & 2003 data)	What are the prevailing attitudes of Yemeni women and their husbands towards FGM/C?	FGM/C	Home, health facility	Family members, society, traditional birth attendants, traditional healers, medical personnel, barbers	Paternal support for or family history of FGM/C; low SES; cultural traditions; low level of maternal education	Septicemia; death; obstructed or prolonged labor, severe postpartum bleeding; post-pregnancy complications	Lack of awareness of FGM/C; stigma associated with reporting
Alosaimi, 2019 [44]	Alazareq (Dhale), Asabrah & Fara'a Aludain (Ibb), Mookaa & Maoza (Taiz), & Azidiah (Al Hudaydah)	4238 women aged 15-49	Rural	Quantitative (secondary data analysis: HBMNC 2008-2009)	What are the factors associated with FGM/C in Yemen?	FGM/C	Home	Family members, traditional healers	Low SES or level of maternal education; mother's FGM/C experience; cultural norms; child marriage; <i>qat</i> use	Risk of neonatal death and low infant birth weight; sexual, mental, and social consequences for women	Poor implementation of laws against FGM/C; cultural norms, including FGM/C as a requirement for

398 violence; TB: tuberculosis; UN: United Nations; WLWH: women living with HIV

399 **Quality assessment**

400 The quality of primary research studies, excluding population-representative studies like
401 DHS and MICS, is summarized in Table S5. The quantitative studies on corporal
402 punishment in schools and experience of child maltreatment and abuse followed similar
403 well-described study designs and sampling frames [40,47–50], but were small in scale
404 and not representative. Most of the included qualitative studies had clearly stated
405 research questions, methods, and findings. However, one article did not specify how the
406 analysis was coded [33], and neither the research question nor methods were clear in
407 one article [31].

408 **Ethical conduct of VAWC research**

409 We adapted the rubric developed by Peterman, et. al., [58] to assess studies'
410 compliance with established norms for the ethical conduct of VAWC research, described
411 in Table 2. Ethical concerns for VAWC research from the DHS and MICS studies is
412 described elsewhere [59–62]. Studies that asked children or young adults about their
413 experience of violence at home (N=3; 12,46,48) or in the classroom (N=3; 44–46)
414 reported ethical clearance, verbal assent from participants, and used paper-based forms
415 that did not collect identifying information. In two studies, where the participants were
416 minors, consent was obtained from the parents [47,48]. The two qualitative studies that
417 interviewed women and girls about their own experience of violence, including sexual
418 violence, did not mention ethical approval or informed consent [21,32]. One of the

419 studies mentioned that interviewers were trained psychology students and that they
420 were accompanied by other women for safety purposes [32]. One quantitative study
421 that interviewed male and female heads of household about their attitudes towards
422 FGM/C, and in the case of women, their own experience of FGM/C, mentioned
423 interviewer training, but did not specify what the training consisted of [46]. One
424 quantitative survey of childhood experience of violence reported that the study team
425 was trained to recognize any signs of distress exhibited as students completed the
426 questionnaire [51]. No study mentioned making safety planning, resource lists, or
427 support services available to participants. In one 2015 study, where female participants
428 were sometimes accompanied by their husbands or older relatives, a second round of
429 interviews was conducted when privacy could be ensured [34]. In resource-limited
430 settings discussing the policy relevance of the findings is especially important to ensure
431 ethical conduct and impact of future research, but most studies did not address the
432 policy implications of their work.

433 **Table 2. Ethical conduct of primary VAWC studies**

Author, year of publication	Population	Focus	Ethics, interviewer training, safety planning
Al Taj, 2023 [46]	Male and female heads of household	Prevalence and attitudes towards FGM/C	Ethical review by Sana'a University, multistage random sampling, verbal IC, mentions interviewer training, but not what interviewers were trained in, interviews conducted in subject's home without others present.

Author, year of publication	Population	Focus	Ethics, interviewer training, safety planning
		child abuse	survey using validated instrument, returned in ballot box for anonymity
Ba-Saddik, 2012 [47]	Secondary school students	Prevalence of and risk factors for emotional abuse in classrooms	Ethical review by Committee of Research and Postgraduate Studies, Faculty of Medicine and Health Sciences, Aden University, written IC from parents, verbal assent from participants, self-completed, anonymous paper survey using validated instrument.
Ba-Saddik, 2013 [48]	Secondary school students	Prevalence of and risk factors for physical abuse in classrooms	Ethical review by Committee of Research and Postgraduate Studies, Faculty of Medicine and Health Sciences, Aden University, Written IC from parents, verbal assent from participants, self-completed, anonymous paper survey using validated instrument.
Ba-Obaid, 2002 [32]	Women aged 15-55	Types of VAW	Multistage sample, trained female interviewers who were psychology students, sometimes accompanied by a second interviewer for safety reasons, interviews conducted in respondent home when adult males are not present.
Alizy, 2017 [51]	Students aged 11-16	Relation between family violence and child behavioral issues	Ethical review from Faculty of Arts and Humanities at Sana'a University, verbal assent from participants, self-completed, anonymous paper survey using validated instrument, participants debriefed after completion of the questionnaire, data collection team trained to handle signs of distress during survey completion.
Ouis, 2009 [21]	Adolescents aged 12-18	Experience of and attitudes towards honor violence, sexual	Convenience sample of participants who had experienced sexual violence, no mention of IC, ethical clearance, resources or support, etc.

Author, year of publication	Population	Focus	Ethics, interviewer training, safety planning
		abuse, early marriage	

434 IC=Informed Consent

435 ***Barriers, tools, strategies, and resources for addressing and reporting violence,***
 436 ***including safety planning***

437 One 2002 study found that only 3% of women who experienced violence went to the
 438 police, preferring to reach out to parents or relatives or not seek any external support
 439 rather than the police or legal support [32]. Two studies reported that women could
 440 only go to the police when accompanied by a male household member, leading to
 441 underreporting of GBV [32,51]. Most studies did not ask women or children about
 442 reporting or whether they accessed any resources to address the violence. Religious
 443 and cultural norms were identified as the most critical barriers to reporting most types
 444 of VAWC [16,36,43,44]. A cross-sectional study that asked dentists about their intention
 445 to report suspected VAWC found that only 60% of dentists would report VAWC to the
 446 police, followed by other agencies in Yemen [55]. A 2017 AMRO regional study by
 447 UNICEF reported that a shortage of skilled NGO personnel and a lack of awareness of
 448 available services were key barriers to accessing resources, as NGOs addressing gender-
 449 related issues do not have the staff to effectively manage reported GBV cases and do
 450 not well understand how to connect women to services or what services are available
 451 [7]. The same study found that girls facing GBV and child marriage experience

452 limitations to their mobility due to gender norms and restricted access to money
453 needed to pay for resources that are generally located outside of their community [7].

454

455 Sexual abuse is highly stigmatized in Yemen, which limits reporting. One study found
456 that women or girls who were sexually abused face “severe punishment” from their
457 parents, who might “kill them” or “force them to marry rapists” [21]. The same study
458 found that adolescent girls in Yemen felt that women and girls could be considered
459 responsible for the sexual violence they experienced [21]. Two studies highlighted that a
460 lack of education for girls and women increases their exposure to violence from
461 husbands compared to more educated women [32,33]. Women reported the
462 widespread cultural beliefs that they are second-class citizens and belong to men, which
463 likely complicates their ability to report violence [32]. Poor implementation of the
464 FGM/C law in Yemen, lack of educational infrastructure, lack of employment
465 opportunities, and the ongoing conflict were also cited as barriers to reporting [44]. Lack
466 of awareness of FGM/C status, which is at a very young age, was also cited as a barrier
467 to reporting [16]

468 **Discussion**

469 This systematic review synthesizes evidence from qualitative and quantitative studies on
470 the types, prevalence, perpetrators of, and risk factors for VAWC in Yemen. The 30
471 studies included in the analysis collected data on a range of forms of VAWC, including

472 honor violence, female genital mutilation and cutting, early and very early marriage,
473 tourist marriage, family and intimate partner violence, school-based violence, and
474 gender inequities in access to food, education, and medical care. Included studies
475 reported a high prevalence of many forms of violence, including corporal punishment in
476 schools and intimate partner violence. We identified seven primary research studies
477 that asked women or children about their experience of violence [21,32,46–49,51] and
478 nine studies that reused data from the Yemen DHS, MICS, PAFAM, and other national
479 and sub-national household surveys [16,35–37,40,42–45]. Six additional studies asked
480 Yemeni dentists about reporting violence [55], students about their attitudes towards
481 women living with HIV [56], gender differences in the prevalence of depression [54],
482 women’s perceptions of self-worth in relation to health-seeking behavior [53],
483 tuberculosis patients on how gender and literacy affect healthcare access [52], and
484 mothers on the factors that cause their fear of childbirth [34]. Studies measured IPV and
485 non-partner family violence (both physical and psychological), sexual violence, early
486 marriage, tourist marriage, child maltreatment, FGM/C, honor violence, child labor,
487 school-based violence, including corporal punishment, and gender inequities in access
488 to health care, education, and food. Studies had very different designs and sampling
489 frameworks, preventing direct comparisons.

490

491 Similar to global trends [63], we found that IPV and other forms of family violence were
492 the most prevalent forms of violence reported in quantitative studies of different types

493 of VAWC. Studies on structural violence in Yemeni society [31,33] linked political
494 instability and social exclusion to GBV, including higher rates of violence and social
495 stigma directed towards marginalized ethnic groups, like the *Muhamasheen*.

496 ***Risk Factors***

497 Risk factors for VAWC included gender inequitable norms and laws, economic instability,
498 lower SES, rural residence, low levels of parental education, and low levels of education
499 in women and girls. IPV and FGM/C were linked to a lack of maternal education, cultural
500 norms and traditions in Yemeni society and, in the case of IPV, restrictive divorce laws.
501 FGM/C was linked to mothers' experience of FGM/C and early marriage. Child
502 maltreatment and early child marriage were related to low levels of parental education
503 and markers of low SES, including larger household size and reduced household income.
504 These findings align with the determinants of VAWC in humanitarian crises in other
505 countries, where cultural, economic, and educational factors are related to the
506 incidence of GBV [64,65]. For example, studies in Sudan and Egypt found that lack of
507 parental education, older age (where older women are more likely to have undergone
508 FGM/C), and patriarchal norms were associated with FGM/C [66,67]. One study included
509 in the review compared attitudes towards honor violence between Yemen, the occupied
510 Palestinian Territories, and Lebanon and found that adolescent girls from Yemen and
511 the Palestinian Territories were more likely than Lebanese girls to believe that women
512 and girls were themselves responsible for their exposure to sexual violence [21].

513 **Barriers to reporting VAWC**

514 Barriers to reporting violence included the lack of gender equitable laws, services or
515 support for women or children who experience violence, and gender-inequitable child
516 custody laws. Studies found that violence, when reported, was reported to family
517 members or the local Sheikh, which is consistent with another study that found stigma
518 and lack of support for women who experienced violence led to underreporting [68].
519 Yemen could consider female police officers to address that barrier to reporting
520 violence [32]. The study also found that educational programs and providing mental
521 health services were effective in reducing violence [68].

522 **Violence against children**

523 Preschool & school-aged children and adolescents reported a higher prevalence of
524 emotional rather than physical abuse, which is consistent with research conducted in
525 South Africa [69,70]. Studies in this review reported low levels of sexual violence against
526 children, which is mirrored in global research and likely related to underreporting [71–
527 73]. Included studies reported that male children experienced higher levels of
528 maltreatment than female children, which was similar to findings from another study
529 conducted in Iran [74] but differed from findings in other Arab countries, including
530 Tunisia and UAE [75]. Although child labor is a significant concern in Yemen, only the
531 2005 MICS measured this form of violence against children. Rates of corporal violence at
532 school and child experience of maltreatment or physical abuse seemed much higher in
533 Yemen than in related contexts, such as Sudan and Syria [76]. One study indicated that

534 children in rural areas encountered elevated levels of corporal punishment in schools
535 [50], which was supported in another study in Mali and Libya [77]. Risk factors
536 associated with child abuse and maltreatment, including gender, older age, rural
537 residence, family socioeconomic status, family size, parent's education, and parent's
538 alcohol use, were similar to those reported in a study in Saudi Arabia [78] and to
539 findings from conflict-affected countries, including Pakistan [79] and Myanmar [80].

540 ***Sexual violence***

541 Sexual violence is a common yet highly stigmatized form of VAWC and is subject to high
542 levels of underreporting [21]. Tourist marriage is a new form of GBV that is a last resort
543 for families with limited resources to feed their families. Tourist marriage was also
544 identified as an emerging concern in a study in Giza, Egypt [81]. Policymakers suggest
545 that poverty reduction and community education [82] can help reduce early marriage in
546 Yemen and other contexts in the Eastern Mediterranean, South and Southeast Asia and
547 Africa [83].

548 ***Female genital mutilation and cutting***

549 Yemen has made strides to prevent FGM/C; however, the government's statement
550 against FGM/C falls short of a nationwide law [44]. In contrast, Egypt has passed a law
551 that prohibits FGM/C and punishes perpetrators [44,67]. Women's empowerment, the
552 involvement of religious leaders, and the education of parents and communities have
553 been cited as pathways towards reducing FGM/C [16,36,43,44].

554 ***Gender inequities in access to medical care, education***

555 Several included studies found gender inequities in healthcare access [35,52,53],
556 education [45], and nutrition [37]. These studies are similar to those in other gender
557 inequitable settings where women and girl children have lower levels of access to food
558 [84], health care [85], and education [86] than males.

559 **Strengths & limitations**

560 This is the first mixed methods systematic review to summarize findings on different
561 forms of VAWC in Yemen. We searched four biomedical databases and NGO websites
562 and used snowball sampling to identify primary and secondary research on VAWC.
563 Limitations stem from the predominantly cross-sectional design of most studies,
564 constraining the ability to infer causality. Future research should focus on longitudinal
565 studies to better understand the dynamics of VAWC over time and explore the efficacy
566 of various intervention strategies. The high levels of stigma surrounding VAWC,
567 especially sexual violence, may have led to underreporting. Most primary research
568 studies, other than the large population-representative surveys like DHS and MICS, did
569 not report on interviewer training to ensure women and children could report on their
570 experience of violence in a safe environment, free of stigma from the interviewer.
571 Adequately funding studies and ensuring that well-funded studies have a coherent plan
572 to address ethical issues in VAWC research could ensure studies on VAWC in Yemen
573 uphold best practices in ethical research on VAWC in resource-limited contexts.

574 **Recommendations for future work**

575 Most studies on VAWC were conducted before the 2014 war in Yemen. The war and
576 pandemic have increased the frequency and forms of VAWC through multiple avenues.
577 The humanitarian research and intervention communities should explore and address
578 the causes and consequences of VAWC, and the international development community
579 should consider investing in research to develop community-based efforts to support
580 Yemeni women and children who experience or have experienced violence, including
581 war-related violence and the associated trauma.

582

583 This review found significant ethical concerns related to existing research, including the
584 absence of informed consent or ethical review. Only two studies, outside of the DHS and
585 MICS, mentioned interviewer training, and none of the studies that interviewed women
586 or children about their experience of violence discussed safety planning or connecting
587 women and children to available resources. Given the lack of resources in Yemen, using
588 positive deviance [87] approaches to identify strategies that would be possible and safe
589 for women and children who experience violence to mitigate or prevent violence.
590 Yemen is a complex context, and Yemeni women and children need to inform the design
591 and execution of research and interventions.

592 **Policy implications**

593 In keeping with policy-related research in Yemen [88], included studies identified severe
594 poverty and displacement, cultural norms, societal stigma, and a lack of sufficient legal
595 protections and support services as barriers to addressing VAWC in Yemen.
596 Humanitarian support for Yemeni families in need is a crucial starting point to curb child
597 and forced marriages [89]. Gender-inequitable child custody laws, cultural beliefs that
598 normalize VAWC, and stigmatizing attitudes towards survivors of violence, including
599 coercive marriages to preserve family honor in the context of sexual violence and
600 blaming divorced women, [90] make addressing VAWC extremely complex. Addressing
601 weak enforcement of protections for women and children [7] and gender inequitable
602 laws or gaps in legislation, including no minimum age of marriage, should be part of a
603 national strategy to address VAWC in Yemen [91]. A locally developed and supported
604 policy action plan is essential for fostering lasting changes in gender-inequitable
605 attitudes towards women and children [92]. This summary of the current landscape of
606 VAWC-related research could support the design of a policy agenda that addresses
607 barriers to measuring, reporting, and responding to VAWC. While not well described in
608 the included studies, the large-scale conflict and related internal displacement have
609 intensified GBV in Yemen [93]. Significant investment is needed in research and services,
610 including basic needs, education, psychological services, and VAWC-related prevention
611 and mitigation to support Yemeni women and children better. Similarly, child labour, an
612 important form of violence that was not well explored in the included studies, should be

613 considered in the research and development agenda [94]. By combining efforts to
614 address gender inequitable laws and harmful cultural practices and providing holistic
615 support to Yemeni families, Yemen can make strides towards reducing VAWC and
616 creating a safer environment for women and children [95].

617 **Conclusions**

618 VAWC is a global public health and human rights issue that affects the global
619 community's ability to achieve most of the 17 SDGs. Violence increases in unstable
620 environments. Understanding and addressing VAWC is context-dependent, requiring
621 meaningful community engagement, cross-sectoral support, and policy action. This SR
622 highlights the high levels of VAWC in Yemen, driven by poverty, displacement, and
623 gender inequitable norms and policies. While we know that VAWC increases during
624 conflicts and when people are displaced, we did not identify any studies on VAWC that
625 collected data after the onset of the ongoing conflict in Yemen, which represents a
626 missed opportunity to understand how the ongoing war has reversed prior gains in
627 reducing the prevalence of child and very early child marriage and introduced new
628 forms of gender-based violence, including tourist marriage. The lack of funding for
629 primary research on VAWC may be one reason why included studies did not report on
630 interviewer training, mental health support for research participants, or safety planning,
631 all of which should be included in VAWC-related research in humanitarian settings or
632 fragile states. Addressing VAWC in Yemen will require a commitment on the part of the
633 international community to fund locally-led efforts to determine immediate and long-

634 term steps to alleviate the factors that drive VAWC (e.g., war, poverty), prevent and
635 mitigate VAWC, and address the effects of VAWC on maternal and child health and
636 related SDGs.

637 **Acknowledgements**

638 We want to thank the participants in the primary research studies included in this
639 review for their courage and honesty in confronting the global challenge of VAWC and
640 the NGOs and researchers working to ensure that their stories are heard and their needs
641 addressed.
