ORCID: 0000-0002-9269-7372 13 14 Abstract 15 Urinary extracellular vesicles (uEVs) are promising non-invasive biomarkers for assessing renal physiology and 16 disease. Focusing specifically on kidney-derived uEVs (kd-uEVs) rather than the overall uEV population may 17 offer a more precise insight into kidney health. However, research distinguishing single kd-uEVs from various 18 nephron segments and their relationship with kidney biology remains limited. Imaging flow cytometry (IFCM) 19 can identify single kd-uEVs by labeling them with CD63 (a uEV marker) in combination with PODXL (a 20 podocyte marker) or AQP2 (a tubular marker). This study investigated the correlations between CD63+ AQP2+ 21 or PODXL+ kd-uEVs and kidney function. CD63+ AQP2+ and CD63+ PODXL+ uEVs were detected in urine 22 compared to negative controls, including urine with detergent treatment or isotype staining and reagent-23 containing PBS. While no significant association was found between CD63+ AQP2+ or PODXL+ uEV 24 concentration and kidney function, a significant correlation was observed between AQP2+ and PODXL+ uEV 25 concentrations (Rho = 0.789, p < 0.001). This correlation could be explained by the colocalization of AQP2 and 26 PODXL on CD63+ uEVs. In conclusion, our study is the first to demonstrate the colocalization of podocyte and 27 tubular proteins on uEVs. 28 29 Keywords: extracellular vesicles; urine, podocyte; renal tubule; cell communication; kidney function

62 Introduction

63 Urinary extracellular vesicles (uEVs) are potential non-invasive biomarkers of renal physiology and disease [1, 64 2]. While the kidney is the primary source, uEVs also derive from the lower urinary tract and the bloodstream 65 [1]. Rather than measuring the overall uEV population, focusing on kidney-derived uEVs (kd-uEVs) may 66 provide a more accurate picture of kidney health. Proteomic analysis of the entire uEVs demonstrated that 67 podocalyxin (PODXL; podocyte marker) and aquaporin 2 (AOP2; tubule/collecting duct marker) are the most 68 abundant kidney-specific proteins [3]. However, research on the discrimination of single kd-uEVs from different 69 nephron segments and their correlation with kidney biology remains limited. Imaging flow cytometry (IFCM) 70 can identify single kd-uEVs by labeling them with CD63 (uEV marker), combined with PODXL or AQP2 [4, 5]. 71 This study aimed to explore the correlations between CD63+ AQP2+ or PODXL+ kd-uEVs and sex, age, and 72 kidney function.

73

74 Methods and Materials

75 Patients and urine collection

Spot urine samples were collected from 30 healthy kidney transplant donors at the Erasmus MC, Rotterdam, The
Netherlands, between August 2018 and August 2021 (clinical parameters are summarized in Supplementary
Table S1). Urine processing protocols, including centrifugation and addition of a proteinase inhibitor to the
supernatant, were described previously [5].

80

81 Isolation-free labeling of uEVs for IFCM

For the labeling of kidney-derived uEVs, 112 μL of urine sample underwent staining with 4 μL of a 30×-diluted
anti-CD63 monoclonal antibody conjugated with allophycocyanin (CD63-APC, 200 μg/mL, clone H5C6,
Biolegend, San Diego, CA, USA), alongside 4 μL of a kidney-specific antibody, in a 96-well plate placed in
darkness overnight at room temperature. The kidney-specific antibody, either a 15×-diluted anti-AQP2
conjugated with Alexa Fluor 488 (AQP2-Alexa488, 200 μg/mL, clone E-2) or a 30×-diluted PODXL-Alexa488
(200 μg/mL, clone 3D3), was obtained from Santa Cruz Animal Health (Dallas, TX, USA).

88

89 To explore the colocalization of AQP2 and PODXL on CD63+ uEVs, a triple-staining protocol was executed for

90 IFCM. Herein, 108 μ L of urine sample was stained with 4 μ L of a 15×-diluted anti-CD63-eFluor450 (200

- 91 μ g/mL, clone H5C6, ThermoFisher Scientific, Waltham, MA, USA), 4 μ L of a 15×-diluted AQP2-Alexa488,
- 92 and 4 μ L of a 20×-diluted PODXL-Alexa647 in darkness overnight at room temperature.
- 93

Before staining, all antibodies were centrifuged at 16,000 g for 10 min. Each stained urine sample was triplicated within the plate, with subsequent analysis employing the median value of the detected uEV concentration. Nonbiological background signals, such as antibody aggregates, were identified based on detergent treatment, which lyses phospholipid and lipid particles. Following each IFCM measurement, all labeled samples were incubated with 5 μ L of TritonX-100 (final concentration of 0.05%) at room temperature for 30 min before re-measurement. Staining specificity was verified using isotypes conjugating with the same fluorophores and at the same concentrations (**Supplementary Table S2**).

101

102 Data acquisition and gating strategy for IFCM

103 The acquisition of Imaging Flow Cytometry (IFCM) data was conducted using an ImageStreamX Mark II 104 instrument (ISx; Cytek Biosciences, Fremont, CA, USA) installed with INSPIRE® software (version 105 200.1.0.765; Cytek Biosciences), following established protocols for analyzing unprocessed urine and plasma [5, 106 6]. The INSPIRE® settings were configured as follows: a flow speed velocity of 40 mm/s, a flow core diameter 107 of 6 µm, 60× magnification, and laser wavelengths of 405 nm (channel 01), 488 nm (channel 02), 642 nm 108 (channel 05), and 785 nm for side scatter (SSC) excitation (channel 06). Additionally, bright-field imaging was 109 conducted using channel 04. Fluorescence signals from eFluor450, Alexa488, and APC (or Alexa647) were 110 detected in channels 01, 02, and 05, respectively.

111

112 Quantification of samples was performed using Amnis IDEAS software (version 6.2; Cytek Biosciences) [5, 6]. 113 To ensure the quantification of individual urinary extracellular vesicles, a specific gating strategy was employed 114 as previously described [6]. In brief: 1) particles exhibiting SSC intensities \leq 5279 a.u., corresponding to EVs \leq 115 1200 nm based on calibration, were selected; 2) only singlets were included, while objects with multiple 116 fluorescent spots were excluded; 3) due to the presence of auto-fluorescence (A-F) particles in unprocessed 117 urine, which exhibit positivity in all channels even without antibody staining and cannot be removed by 118 detergent [6], A-F particles showing positivity in an empty channel 03 (no antibody) were excluded from the 119 analysis; 4) gates were set up to identify single, double, or triple-positive uEVs based on unstained, isotype-120 stained, and single-stained control samples.

122 Immunohistochemistry

123 The tissue specificity of anti-AQP2 (clone E2, Santa Cruz) and anti-PODXL (clone 3D3, Santa Cruz) antibodies 124 was assessed via immunohistochemistry experiments conducted on formalin-fixed paraffin-embedded (FFPE) 125 sections obtained from residual peritumoral tissue from nephrectomies performed for oncological purposes 126 (Supplementary Fig. S1). Immunohistochemistry Chromogenic multiplex (cmIHC) analysis was conducted 127 using an automated cmIHC system, specifically the Ventana Benchmark DiscoverAy ULTRA (Ventana Medical 128 Systems Inc., Oro Valley, AZ, USA).

129

130 In summary, 4 µm thick tissue sections were stained following deparaffinization and heat-induced antigen 131 retrieval with CC1 (#950-224, Ventana) for 32 minutes. A 4000× dilution of anti-podocalyxin ligand 1 was 132 incubated at 37°C for 32 minutes, followed by treatment with omnimap anti-mouse HRP (#760-4310, Ventana) 133 and detection with purple (#760-299, Ventana) for 32 minutes. An antibody denaturation step was then 134 performed with CC2 (#950-123, Ventana) at 100°C for 20 minutes. Subsequently, incubation with a 100× 135 dilution of anti-AQP2 was conducted at 37°C for 32 minutes, followed by mouse-NP and anti-NP-AP (#760-136 4816 and #760-4827, Ventana) and detection with the Yellow AP kit (#760-239, Ventana). Counterstaining was 137 performed with hematoxylin II for 4 minutes, followed by a blue coloring reagent for an additional 4 minutes, as 138 per the manufacturer's instructions (Ventana). Finally, slides were scanned using the Hamamatsu Nanozoomer 139 (Hamamatsu Photonics, Hamamatsu, Japan).

140

Reagent-containing phosphate-buffered saline (PBS), detergent-treated urine, and isotype-stained urine were
used to validate the uEV measurement [1]. As recommended by the International Society for Extracellular
Vesicles [1], urine dilution was normalized by calculating the concentration ratio of uEVs to urinary creatinine
(UCr) measured with CRE2U, ACN 8152 (Roche Diagnostics Nederland BV).

145

146 Statistical analysis

Data were presented as median [quartile 1 – quartile 3; Q1 – Q3]. Correlations between sex, age, eGFR, and
UCr-normalized AQP2+ or PODXL+ uEV concentrations were examined using Spearman's correlation. Linear
regression analyses were performed between eGFR, log-transformed UCr-normalized AQP2+ uEV, and
PODXL+ uEV concentrations. A schematic overview of sample collection, processing, and staining is illustrated
in Supplementary Fig. S2.

153 **Results**

CD63+ AQP2+ uEVs (Fig. 1a) and CD63+ PODXL+ uEVs (Fig. 1b) were clearly present in urine compared to 154 155 the negative controls, including detergent treatment, reagent-containing PBS, and isotype staining (Fig. 1c - 1g). 156 The medians of UCr-normalized CD63+ AQP2+ uEV and CD63+ PODXL+ uEV concentrations were 3.5 [Q1 -157 Q3: $0.8 - 6.8 \times 10^4$ objects/µmol and 3.6 $[1.2 - 7.7] \times 10^4$ objects/µmol, respectively, with less than 20% of 158 these uEVs measured in detergent-treated or isotype-stained urine (Fig. 1h; all p values < 0.001). With the 159 presence of detergent, 40 - 90% of objects stained negative for CD63 but positive for AQP2 or PODXL (Fig. 1c, 160 1d). In addition, compared to urine (Fig. 1a, 1b), reagent-containing PBS contained 10% of CD63-negative and 161 AQP2/PODXL-positive backgrounds (Fig. 1e, 1f), indicating free antibody aggregations rather than biological 162 uEVs. No significant association was observed between CD63+ AQP2+ or PODXL+ uEV concentration and 163 sex, age, or eGFR, but a significant correlation was found between AQP2+ and PODXL+ uEV concentrations 164 (Rho = 0.789, p < 0.001; Fig. 1i). Regression analyses were used to visualize these correlations, which also 165 demonstrated weak associations between eGFR and AOP2+ uEV concentrations ($R^2 = 0.00$, p = 0.98; Fig. 1j) or 166 between eGFR and PODXL+ uEV concentrations ($R^2 = 0.04$, p = 0.30; Fig. 1k). However, a higher level of 167 PODXL+ uEVs was significantly associated with a higher AQP2+ uEV level ($R^2 = 0.64$, p < 0.001; Fig. 11). To explore whether AOP2 colocalizes with PODXL on the CD63+ uEV surface, we performed CD63-AOP2-168 169 PODXL triple staining. About 50% of the CD63+ uEVs expressing PODXL were triple-positive and expressed AQP2 (Fig. 1m). Representative images for AQP2+ PODXL+ CD63+ uEVs are displayed in Fig. 1n. The 170 171 specific colocalization of AQP2 and PODXL on CD63+ uEVs was strengthened by the negative controls and 172 rare AQP2 and PODXL double-positivity measured in CD63- events (Supplementary Fig. S3). The median of UCr-normalized triple-positive uEV concentration was 6.4 $[4.0 - 14.9] \times 10^3$ objects/µmol, significantly higher 173 174 than in controls with detergent treatment (p = 0.004) or isotype staining (p < 0.001; N = 10; Fig. 10).

175

176 Discussion

This study investigated the association between kidney biology and podocyte-derived PODXL+ uEVs as well as tubule/collecting duct-derived AQP2+ uEVs. There was no correlation between these kd-uEV levels and sex, age, or eGFR. Despite the substantial anatomical distance between podocytes and collecting duct cells, a significant correlation was found between the uEVs expressing AQP2 and PODXL, which can be explained by the partial colocalization of these proteins on uEVs. Collecting duct cells are active in absorbing podocytederived uEVs [7]. Endocytosis is a typical way to uptake external vesicles, allowing the endosomal system to

183 package native molecules and release exosomes, a distinctive uEV subtype marked by CD63 expression [8]. This 184 procedure can lead to vesicle membrane reversion or the presence of inside-out proteins on its surface [9]. Our AQP2 antibody targets its intracellular domain, which typically faces the lumen of vesicles rather than the 185 186 exterior environment [10]. Therefore, the presence of uEVs with exterior AQP2 further suggests their endosomal 187 origin [10]. Our study provides evidence of EV-mediated protein delivery in the human nephron, which gives 188 new insights into the intra-nephron cross-talk and kidney biology. 189 190 The limitation is that other kidney-specific markers on uEVs, such as tubular co-transporters, were not measured. 191 Characterization of more markers can help understand the role of EVs in kidney physiology, but our study, for 192 the first time, demonstrates the colocalization of podocyte and tubular proteins on uEVs. Further investigations 193 are needed to confirm these findings and fully explore uEV-mediated communication in nephron health and 194 disease. 195 Conclusion 196 197 The release of PODXL+ or AQP2+ CD63+ kd-uEVs is not correlated with kidney function. The correlation 198 between these two uEV populations can be explained by the colocalization of PODXL and AQP2 on CD63+ 199 uEVs. 200 201 Supplementary file 202 This study contains a supplementary file. 203 204 **Authors' contributions:** 205 Conceptualization: [Liang Wu], [Carla C.
