23 mentorship provided by the DLSPH Implementation Science Trainee Cluster Program at the
24 University of Toronto Dalla Lana School of Public Health.

26 Abstract

27 **Objectives:** This study examined how six Canadian provinces (Alberta, British Columbia,
28 Manitoba, Nova Scotia, Ontario, Quebec) adapted guidelines from the National Advisory
29 Committee on Immunization to prioritize COVID-19 vaccines equitably for five key populations
30 at high risk: Black communities; First Nations, Inuit, and Métis populations; non-medical
31 essential workers; individuals experiencing homelessness; and individuals with disabilities. The
32 objective was to compare timelines, justifications, and contextual factors that influenced
33 provincial prioritization for early vaccine access.

34
35 **Methods:** A mixed-methods approach was used to investigate how provinces operationalized
36 equity in their vaccine rollout plans. Environmental scans (December 2020 – May 2021)
37 gathered data on prioritization and distribution from provincial reports and media articles. Key
38 informant interviews (December 2021 – April 2022) with provincial experts provided context on
39 decision-making and justifications for prioritizing key populations. Data analysis employed the
40 “Reach” component of the RE-AIM framework, with qualitative analysis of interviews following
41 an interpretive descriptive approach.

42
43 **Results:** Provinces used age-, risk-, and health status-based approaches to select priority
44 populations. While all provinces consulted the National Advisory Committee on Immunization
45 guidelines and various ethical frameworks to guide their decisions, deviations occurred due to
46 local contexts. First Nations, Inuit, and Métis populations were prioritized earliest in all
47 provinces, while Black communities received the least prioritization. Key subgroups, such as

48 urban First Nations, Inuit, and Métis, unsheltered homeless individuals, and homebound
49 disabled persons, were often overlooked. Factors that emerged as key drivers of priority
50 population selection were data availability, population size, and geography.

51

52 **Conclusions:** This study fills gaps in the literature by highlighting key contextual factors unique
53 to each province that drove provincial justifications for their prioritization decisions. We
54 provide several examples of the importance of data availability and early community-led
55 partnerships when designing a successful mass vaccination rollout.

56 Introduction

57 The COVID-19 pandemic took a significant health and economic toll globally with its high
58 infectivity and mutation rate. Its morbidity and mortality burdens were on a scale unobserved
59 since the 1918 Spanish influenza¹. Although regulators around the world authorised COVID-19
60 vaccines for emergency use in record time for their respective countries, nations still had to
61 acquire sufficient vaccine doses and then plan how to efficiently and equitably distribute the
62 vaccine to all communities in order of risk². All countries, regardless of income status, were
63 forced to grapple with the limitations of their existing public health infrastructure and the state
64 of their partnerships with communities in need.

65
66 In Canada, the collective federal, provincial, and territorial pandemic response goal was to
67 “minimize serious illness and overall deaths while minimizing societal disruption” caused by
68 COVID-19³. Although Health Canada approved the first COVID-19 vaccines for emergency
69 distribution in December 2020, there was a global shortage of vaccines early in the rollout⁴. By
70 the end of January 2021, the Canadian government secured about 1 million vaccine doses for a
71 population of about 38 million, with shortages persisting until early April 2021⁴⁻⁶. Furthermore,
72 the first two approved mRNA-based vaccines, manufactured by Moderna and Pfizer-BioNTech,
73 had stringent cold storage requirements of -20°C and -80°C, respectively⁷⁻⁹. Vaccine supply
74 chains in Canada were not adequately prepared to transport these vaccines efficiently to
75 remote areas where the need was often the most critical¹⁰⁻¹². Moreover, most approved
76 vaccines required a minimum of two doses to be considered protected, necessitating additional
77 planning around when to prioritize populations for their primary dose series, and how to follow

78 up with transient populations to ensure full coverage². Given these on-the-ground realities,
79 Canadian jurisdictions had to make difficult decisions regarding which populations to prioritize
80 for vaccine distribution until more doses could be acquired.

81
82 Amidst such a challenging scenario characterized by high demand and limited vaccine supply,
83 concerns regarding the fair distribution of vaccines inevitably surfaced within Canada and
84 worldwide^{13–16}. Drawing from lessons learned from past pandemics such as H1N1¹⁷ Canada
85 recognized the need for early, equitable access to COVID-19 vaccines within its own borders¹⁸.
86 This was further energized by a societal and global consensus, led by international technical
87 advisory groups on immunization (e.g. the United Kingdom’s Joint Committee on Vaccination
88 and Immunization and France’s Haute Autorité de Santé), that equitable distribution was not
89 only ethically imperative but also pivotal for limiting the spread of the COVID-19 virus^{19,20}.

90
91 Canada’s national immunization technical advisory group, the National Advisory Committee on
92 Immunization (NACI), was tasked with developing federal guidelines to ensure equitable COVID-
93 19 vaccine distribution²¹. Provinces and territories were then responsible for implementing and
94 adapting these recommendations to their local contexts²². Using the Ethics, Equity, Feasibility,
95 and Acceptability (EEFA) framework, NACI defined equity as the “absence of avoidable, unfair,
96 or remediable differences among groups, whether those groups are defined socially,
97 economically, demographically, or geographically or by other means of stratification”²¹. These
98 guidelines suggest that equity considerations, in addition to the standard age-based rollout,
99 were essential to mitigating the negative impacts of the pandemic. Therefore, NACI

100 recommended phased prioritization of key populations who were grouped into four major
101 categories: (1) those at high risk of severe illness and death from COVID-19 due to poorer
102 health; (2) those at high risk of exposure and transmission due to the nature of their occupation
103 or workplace; (3) those who maintain essential services; and (4) those who work or live in
104 conditions that put them at high risk of infection with disproportionate consequences^{21,23}. NACI
105 recommended priority populations and dosing intervals by summarizing the best available
106 evidence of existing risk data at the time, updating its guidelines throughout the vaccine rollout
107 as more evidence became available^{24,25}.

108
109 Our research group selected five key populations that were highlighted by NACI in the early
110 stages of the rollout (late 2020 / early 2021) as experiencing a significantly higher risk of
111 negative outcomes or barriers to vaccination than the general population²⁵⁻²⁷. These
112 populations were Black communities; First Nations, Inuit, and Métis populations; non-medical
113 essential workers; individuals experiencing homelessness; and individuals with disabilities²⁵⁻²⁷.
114 We applied an equity lens to examine the variability in when and how Canadian jurisdictions
115 chose to prioritize these populations across provinces. We also investigated how provinces
116 considered contextual factors such as population size and distribution; current COVID-19
117 prevalence rates among specific populations^{28,29}; and geographic and occupational risk
118 exposures²⁹ that can significantly influence vaccine uptake.

119
120 This paper uses an implementation science approach to examine how six Canadian provinces
121 considered and adapted NACI guidance regarding the equitable prioritization of COVID-19

122 vaccines for the above study populations during the primary dose series phase of the rollout
123 (December 2021 to April 2022). Specifically, we:

124

125 1. Compared justification and timelines for prioritization used by the provinces for
126 prioritization of the key populations.

127

128 2. Identified contextual factors that influenced how provinces selected priority populations
129 for early COVID-19 vaccine access.

130

131 This paper is one of three publications conducted by our research team as part of a larger
132 research project^{30,31}.

133 **Materials and Methods**

134 Comprehensive environmental scans and key informant interviews informed our understanding
135 of each province's vaccine rollout plan, including any ethical frameworks used, the order of
136 prioritization (timelines), and justifications provided for and the context around provincial
137 decisions regarding prioritization of our five study populations. To ensure transparent and
138 comprehensive reporting, we adhered to the COnsolidated criteria for REporting Qualitative
139 research (COREQ) checklist, guiding the documentation of our study Methods and Results³². For
140 a detailed reference, please consult S1 Appendix for the COREQ checklist. Approval for the
141 research was obtained from the University of Toronto (UofT) ethics committee (REB protocol
142 #28098).

143 Researcher Characteristics

144 The research team, consisting of graduate students and research mentors from the UofT, was
145 established through the Dalla Lana School of Public Health (DLSPH) Implementation Science
146 Trainee Cluster Program at the UofT. The student researchers consisted of six doctoral students
147 (four females: KB, MO, MS, VA; two males: CD, DMV) specializing in epidemiology, health
148 services research, or public health sciences. They were guided by three female mentors (AA, SA,
149 SF) with experience in implementation science, population health and immunity, health
150 systems and policies, health system performance, and health equity. Representing diverse
151 ethnicities and lived experiences, this multidisciplinary team brought a wealth of expertise to
152 the study, including in implementation science, health equity research, infectious disease
153 outbreak investigations, and vaccine science and policy. All team members had prior experience
154 in qualitative research, including conducting structured or semi-structured interviews and
155 interview-based questionnaires with various stakeholders such as key informants, community
156 leaders/members, or patients. Additionally, several team members specialized in community-
157 based, participatory action research, particularly among marginalized or vulnerable
158 populations.

159 Study Population and Context

160 We analysed prioritization plans for five key populations: Black communities, First Nations,
161 Inuit, and Métis populations (FNIM), non-medical essential workers, individuals experiencing
162 homelessness, and individuals with disabilities across six Canadian provinces (Alberta, British
163 Columbia, Nova Scotia, Manitoba, Ontario, and Quebec). Our five population groups were
164 selected because they were prioritized by NACI as being at substantial risk of transmission and

165 outbreaks, severe illness, and/or barriers to vaccine uptake²¹. We narrowed our study to the
166 above six provinces after a preliminary environmental scan our team conducted of all Canadian
167 jurisdictions. We concluded that these provinces had the most publicly available data on
168 published prioritization plans and implementation timelines. Additionally, they provided a
169 representative snapshot of the diversity of Canadian jurisdictions, in terms of population size
170 and constitution, resources, and geography.

171
172 We also investigated how subgroups within our five populations of interest were prioritized, as
173 our pilot scans indicated that there were differences in the extent to which these groups were
174 prioritized across provinces. First, we defined Black communities as including people of African
175 or Caribbean ancestry who live in Canada. Second, we examined prioritization for on- and off-
176 reserve, urban, and remote FNIM populations. For essential workers, we narrowed our focus to
177 only examining workers in non-healthcare settings because our preliminary scans indicated that
178 essential workers in health-related settings (e.g. healthcare workers, staff in congregate
179 settings, etc.) were prioritized first across all provinces. Additionally, we were interested in how
180 provinces defined essential workers in their rollout plans as part of our analysis. This provided
181 further context for how and why prioritization decisions were made for this diverse group. For
182 individuals experiencing homelessness, we considered both those who lived in shelters (or
183 individuals in second-stage housing) as well as those with precarious living conditions (e.g. not
184 living in shelters, living on the streets, experiencing unstable housing, etc.). Finally, among
185 individuals with disabilities, we focused on individuals facing significant barriers to vaccination
186 due to either developmental (e.g., severe developmental delays, individuals in institutionalized

187 care) or physical challenges (e.g., homebound individuals). Overall, we wanted to keep in mind
188 our key study objective of studying populations at high risk of negative outcomes and/or
189 barriers to vaccine access.

190

191 Data Collection

192 We used a two-step, mixed-methods approach to assess provincial efforts to reach priority
193 populations. We first conducted environmental scans of the six provinces between December
194 1st, 2020, and May 31st, 2021, followed by key informant (KI) interviews between December
195 1st, 2021, and April 30th, 2022. The study period began when emergency vaccines were
196 approved in Canada (Dec 2020) and ended just before all provinces reached their general
197 population vaccination phase (around June 2021), as it was assumed that all high-risk
198 populations requiring early prioritization would have been reached by that point. This period
199 was selected to capture initial provincial decisions that were made about which populations to
200 prioritize and strategies that were implemented for the primary dose series (first and second
201 doses), in response to significant vaccine shortages and delays at the beginning of the rollout.

202

203 Environmental Scans

204 For environmental scans, we reviewed provincial reports, statements, and scientific or media
205 articles, released between December 2020 and May 2021, related to vaccine prioritization plans
206 for our five key populations. We intentionally focused on provincial government-led efforts to
207 reach priority populations, excluding community or grassroots initiatives that addressed gaps in
208 provincial-led outreach, such as those facilitated by organizations like the Health Association of

209 African Canadians in Nova Scotia^{33,34}, unless provinces intentionally collaborated with these
210 community groups as part of their pre-determined strategy to prioritize and engage with
211 communities (e.g. Black churches in Nova Scotia³⁵). For the Environmental Scan Data Collection
212 Tool used, please consult S2 Appendix.

213
214 The extracted data was used to generate a single summary for each province detailing their
215 COVID-19 vaccine prioritization plans for our priority populations. For each key population, the
216 summaries detailed the extent to which they were prioritized (if it all), along with the timeline
217 and methodologies employed for vaccine implementation. Additionally, the summaries
218 included justifications listed on provincial websites that would indicate how decision-makers
219 rationalized their choices.

220
221 Environmental scans were conducted in two stages. Preliminary scans were conducted before
222 KI interviews, and the initial findings were shared with KIs for validation, correction, and
223 additional information. After incorporating feedback from the KIs (see below), a final
224 environmental scan summary was compiled, incorporating any new data released since the
225 initial scan and contextual information or corrections provided by KIs.

226
227 [Key Informant Interviews](#)

228 To contextualize and validate our environmental scan findings, we conducted KI interviews with
229 public health experts involved in the vaccine rollout across provinces between December 2021
230 and April 2022. The research team invited a total of 89 KIs from the six study provinces. KI

231 interviews were carried out until reaching saturation, comprising 31 interviews with 41
232 participants. Generally, interviews were conducted with individual KIs, unless they specifically
233 requested a group interview. Of the 31 interviews conducted, 25 were individual sessions and
234 six took place in groups of 2 to 4 individuals. To ensure comprehensive representation for each
235 province, we conducted a minimum of 4 interviews per province. Two KIs later decided to
236 withdraw their interviews from the study over concerns of being identified.

237
238 KIs chosen for our study held diverse roles in public health, including medical officers of health,
239 vaccine task force leads, physicians, members of pandemic response teams, medical
240 anthropologists, public health experts, and representatives from NACI. Of the 31 interviews, 27
241 (87%) represented academic, government, or research institutions, while 13% were affiliated
242 with community organizations. Notably, approximately 90% of participants had prior
243 experience with communicable disease control and vaccine delivery programs before the
244 COVID-19 pandemic.

245
246 KIs were selected through a comprehensive review of publicly available information on key
247 decision makers and stakeholders involved in COVID-19 vaccine rollout committees, working
248 groups, advisory panels, task forces, as well as through the social networks of the team. Two
249 members of the research team (MO and CD) sent invitation emails to selected individuals in
250 stages, with up to two follow-up emails when necessary. A group of informants received the
251 initial invitation; if there were no responses, additional potential informants from the
252 respective province were contacted. Interested informants received an information sheet

253 detailing the study's objectives along with a consent form. Participation incentives were not
254 provided. Those who accepted the invitation were scheduled for an online interview using
255 Zoom.

256
257 Prior to the interviews, participants were asked to review our environmental scan summary of
258 the COVID-19 vaccine rollout plan for their respective province. During the interview, KIs were
259 asked to verify the accuracy of the findings from the environmental scan. They were also given
260 the opportunity to offer any corrections or supplementary information during the interview or
261 afterward via email. At the end of each interview, KIs were asked to recommend any potential
262 informants that they believed could contribute to the issues discussed in the study. Those
263 referred were then contacted by either the study team or directly by the referring KI, similar to
264 a snowball sampling method of recruiting participants³⁶.

265
266 Interviews were semi-structured, following an interview guide but allowing interviewers to ask
267 probing questions for more information if needed (Refer to S3 Appendix for the Interview
268 Guide). The interview guide was pilot tested by research team members. Interviews were
269 scheduled for 1.5 hours each and generally took the full time. KI interviews were primarily
270 conducted by two members of the research team (MS and VA) with support from two team
271 members (KB and CD) on two separate occasions due to scheduling conflicts. Researchers
272 conducted interviews from private rooms with KIs to ensure confidentiality. All interviews were
273 conducted over Zoom and were audio recorded after expressly seeking participant consent.
274 Preliminary transcription was completed by the Zoom platform. Transcripts were further

275 reviewed by all student research members. Within two weeks of each interview, KIs received
276 the cleaned transcript for review and were given the opportunity to respond via email with any
277 concerns they had regarding the accuracy of captured information.

278

279 Data Analysis

280 Our analysis was guided by the “Reach” component of the RE-AIM implementation science
281 framework³⁷. Using this framework, we were able to implement a content analysis approach of
282 extracting data on the prioritization of populations and the strategies employed to promote
283 COVID-19 vaccine uptake. The “Reach” component of RE-AIM framework assesses the extent
284 to which an intervention or program effectively reaches its intended target population and
285 achieves broad reach among the individuals or groups it aims to impact³⁸. Although the RE-AIM
286 framework has four other components (effectiveness, adoption, implementation, and
287 maintenance), we determined that “Reach” was the only component that would sufficiently
288 address our project goals during our study time period, which was very early on in the rollout.
289 We conceptualized our study around September 2020, prior to the first COVID-19 vaccines
290 being licensed (December 2020). NACI guidelines on reaching priority populations and
291 provincial vaccine rollout plans were just starting to get published. We concluded that it would
292 be premature to utilize the full RE-AIM framework since it would likely take several months, if
293 not a few years, to determine the effectiveness of these policy plans, how well they were
294 adopted and implemented, and whether they were successful enough to incorporate into
295 regular policy practices over time.

296

297 Guided by “Reach”, we focused on the first two of four indicator questions (Table 1) to
298 determine the following for each province: (a) if and when each of the five key populations was
299 prioritized and (b) how provinces justified their prioritization decisions to the general public.
300 Obtaining answers to these study objectives drove how we structured our environmental scans
301 as well as the themes analysed from the KI interviews.

302

303 **Table 1. Data analysis guiding questions.**

1	Was this population prioritized? If so, when?
2	Were there clear communication and justification for the choice of this population?
3	What strategies or interventions, if any, were used to reach or engage with the prioritized population?
4	What strategies or interventions, if any, were used to overcome potential challenges to access the vaccine for those populations, including strategies to improve trust and reduce hesitancy?

304

305 To analyse KI interview data, we first employed an interpretive descriptive qualitative
306 approach³⁹. Transcripts were managed using NVivo 12 software and independently analysed by
307 members of the research team (KB, MO, CD and DMV) through inductive thematic analysis. This
308 inductive approach allowed for a deep exploration of the context surrounding vaccination
309 strategies and implementation, facilitating the identification of patterns, categories, or themes
310 not previously considered^{39,40}, thereby enhancing the study's rigor by ensuring the findings
311 were grounded in the data³⁹.

312

313 Coding followed Creswell's approach^{41,42}, wherein each transcript was initially read, and key
314 ideas or responses relevant to the study objectives were independently highlighted by two
315 team members. These ideas were then assigned a "code," with operational definitions ensuring
316 consistent application across the data. Similar codes were grouped to form broader themes,
317 serving as the main units of analysis⁴¹. Summaries were then developed for each theme by
318 reviewing all coded data, a process completed by two team members (KB and MO), with
319 revisions and consensus on themes achieved through regular meetings and discussions among
320 team members. Any discrepancies in coding, categorization, or definitions were discussed, with
321 consensus sought throughout the analysis process.

322 Results

323 Objective 1: Compare justification and timelines used by the provinces for
324 prioritization of key populations

325 Overall provincial approaches to population prioritization and ethical frameworks used in
326 designing vaccine rollout plans

327 Table 2 summarizes each province's overall public health approach in determining priority
328 populations and any ethical frameworks identified. KIs confirmed that all provinces consulted
329 NACI guidelines, including NACI's EEFA framework, to guide their decisions regarding priority
330 populations, vaccine delivery, and storage. According to our environmental scans and KI
331 interviews, provinces utilised a combination of age-, risk-, and health status-based approaches
332 to select priority populations, in accordance with NACI guidelines. How provinces defined risk
333 varied depending on their local contexts, ranging from protecting those at risk of developing

334 severe illness, minimizing transmission in workplaces or in remote regions, or maintaining the
 335 function of critical provincial services.

336 **Table 2. Overall public health approach to population prioritization, frameworks used to**
 337 **guide decisions, and level of adherence to NACI recommendations.**

Province:	Selection of priority populations based on:	Main frameworks, including any ethical frameworks, identified:	Deviations from NACI:
Alberta	Risk- then age-based prioritization AIM: protect those at highest risk of poor outcomes; prevent transmission, particularly in remote regions	NACI’s EEFA framework*, with province-specific modifications. Policy document titled <i>Appropriate Prioritization of Access to Health Services</i> (developed in Dec 2015) used as formal ethical framework ⁴³	Did not prioritize Black communities directly in policy rollout plan “ Hot spot ” strategy employed for regional prioritization
British Columbia	Age- and health status-based approach AIM: protect those at risk of developing severe illness; maintain the workforce for critical services	NACI’s EEFA framework, with province-specific modifications British Columbia Centre for Disease Control’s (BCCDC) COVID-19 Ethical Decision-Making Framework ⁴⁴	Did not prioritize Black communities directly in policy rollout plan “ Hot spot ” strategy employed for regional prioritization
Manitoba	Risk-based (workplace exposures, living arrangement) followed by age-based prioritization and sustaining healthcare services AIM: prevent workplace exposures and sustain healthcare services, then protect those at risk of developing severe illness	NACI’s EEFA framework, with province-specific modifications Manitoba’s Vaccine Immunization Task Force’s ‘full immunization fast’ policy ⁴⁵	Did not employ a phased approach to the vaccine rollout Did not prioritize Black communities directly in policy rollout plan MFNPRCT* recommended First Nations children (5-11 yrs) to receive second dose within 21 days of first dose (NACI recommended 8-wk interval)

			“Hot spot” strategy employed for regional prioritization
Nova Scotia	<p>Primarily age-based prioritization followed by risk of exposure due to difficulties adhering to public health protocols</p> <p>AIM: prevent morbidity and mortality; sustain healthcare services.</p>	NACI’s EEFA framework, with province-specific modifications.	<p>Did not prioritize certain NACI-recommended priority groups because of strict adherence to age-based rollout policy:</p> <ul style="list-style-type: none"> • Individuals at risk of severe illness due to medical factors (e.g. pregnancy, disabilities, and other underlying medical health conditions) • Certain NACI-recommended essential workers (e.g. teachers, grocery store employees) • Prioritized single-dose vaccines (e.g. Janssen) for populations predicted to be challenging to follow up
Ontario	<p>Risk- and age-based prioritization</p> <p>AIM: protect those at risk of developing severe illness</p>	<p>NACI’s EEFA framework, with province-specific modifications</p> <p>Ontario COVID-19 Vaccine Distribution Task Force’s Ethical Framework⁴⁹ (published in Dec 2020), which was adapted from NACI’s EEFA framework</p>	“Hot spot” strategy employed for regional prioritization
Quebec	<p>Age- then risk-based prioritization</p> <p>AIM: protect those at risk of developing severe illness</p>	<p>Provincial rollout plan was primarily informed by the Erickson and De Wals framework⁴⁷ (developed in 2005), which was used to guide NACI’s EEFA framework</p> <p>Quebec’s Immunization Committee (Comité sur l’Immunisation du Québec, CIQ) also consulted other</p>	<p>Did not prioritize Black communities directly in policy rollout plan</p> <p>Delayed delivery of second dose for 16 weeks (NACI recommended 21-and 28-day intervals for Pfizer and Moderna, respectively) to maximize first-dose delivery to priority groups 1-6⁴⁸. Based</p>

		expert groups, including Canada’s NACI guidelines (EEFA framework), WHO, CDC (U.S.), JCVI (U.K.), and HAS (France)*	on success, this strategy was later adopted by NACI ^{49,50} .
--	--	---	--

338

339 * EEFA = Ethics, Equity, Feasibility, and Accessibility Framework; NACI = National Advisory Committee on

340 Immunization; ON-MOH = Ontario Ministry of Health; MFNPRCT = Manitoba First Nations Pandemic Response

341 Coordination Team; WHO = World Health Organization; CDC = Centers for Disease Control and Prevention; JCVI =

342 Joint Committee on Vaccination and Immunization; HAS = Haute Autorité de santé

343

344 Table 2 also summarizes notable ways in which provinces deviated from NACI guidelines based

345 on their local contexts. First, four provinces (Alberta, British Columbia, Manitoba, and Quebec)

346 did not directly prioritize Black communities in their vaccine rollout policies, despite being

347 specifically mentioned by NACI as a racialized group at higher risk of developing severe

348 outcomes due to systemic barriers to accessing healthcare²⁷. Justifications provided by

349 provinces for this choice are discussed in the next section. Second, multiple provinces (Alberta,

350 British Columbia, Manitoba, and Ontario) employed a “hot spot” strategy for regional

351 prioritization to reach key demographics that could not be easily captured through other

352 strategies, a method that was not mentioned by NACI. Third, Quebec and Manitoba deviated

353 from NACI-recommended dosing intervals due to provincial considerations regarding how to

354 balance prioritizing those most at risk with reaching the most people amidst early vaccine

355 shortages⁴⁸. Quebec’s strategy was later adopted by NACI in March 2021 because of increasing

356 scientific evidence of the usefulness of this strategy, particularly during the early vaccine

357 shortages from January to March 2021^{49,50}. Fourth, Nova Scotia made an early decision to

358 strictly adhere to a primarily age-based rollout⁵¹⁻⁵³, with very few notable exceptions that will

359 be discussed later. While age-based prioritization was consistent with NACI recommendations,
360 Nova Scotia deviated from NACI by intentionally not prioritizing certain populations
361 recommended in NACI's equity matrix²¹. This included individuals with underlying medical
362 conditions, individuals with disabilities, as well as certain groups of essential workers^{25,27,52,54}.
363 Provincial justifications for this decision will be discussed later. Finally, many provinces
364 employed a phased vaccine rollout strategy, as was consistent with NACI guidelines²⁷, while
365 Quebec used a similar rank-based system of prioritization (Fig 1). However, Manitoba used
366 what it referred to as a "full immunization fast" policy rather than a phased approach⁴⁵, where
367 eligibility was based on vaccine availability. Eligibility was communicated to the public through
368 regular COVID-19 Vaccine Bulletins and news releases.

369

370 **Fig 1. Timeline of prioritization of five key populations across six provinces.**

371 *, **, ***: Detailed list of essential worker categories is listed in Table 4.

373 developmental; CLdS = Community Living disABILITY Services

374

375 Justifications and timelines provided by the provinces for prioritization of key populations:

376 According to our environmental scans and KIs, prioritization of our study populations varied

377 between provinces. For this section, Fig 1 provides detailed timelines for prioritization by

378 province and study population. Table 3 provides a summary of justifications provided by

379 provinces for their prioritization choices.

380 **Table 3. Justification provided by provinces for their choice of prioritization of key populations.**

Justification provided	Black communities	FNIM populations	Non-medical essential workers	Individuals experiencing homelessness	Individuals with disabilities
High risk of transmission or severe illness due to social, economic, or structural factors	NS, ON	AB, MB, NS, ON, QC	AB, BC, QC	AB, BC, ON, QC	
High risk of severe illness due to underlying medical conditions		MB, QC		QC	AB, BC, MB, ON, QC
Hard to reach / remote or isolated communities		AB, BC, MB, ON, QC		AB, BC	ON
High risk of outbreaks due to living in congregate settings			BC, MB, NS	AB, BC, MB, NS, ON, QC	BC
Historical evidence of inequities or injustices that impact vaccine confidence/uptake	NS, ON	AB, MB, ON, QC			
Work in critical non-medical essential services <u>and</u> unable to work from home			BC, NS, ON, QC		
“Hot spot” community (N/A for NS and QC)	ON		BC, MB, ON		
Real-time risk data	ON	AB, MB			AB
Other justification(s)		Instill community trust in provincial vaccination plan (MB) Difficulty applying isolation measures; reduced access to	Consistently travel into and out of province (NS)	Cannot maintain public health safety protocols (QC) Difficulty following up with transient populations (AB)	

		specialized healthcare services (QC)			
Not prioritized	AB, BC, MB, QC				NS

381

382 AB = Alberta; BC = British Columbia; MB = Manitoba; NS = Nova Scotia; ON = Ontario; QC = Quebec

383 *Black communities:*

384 Black communities were the least prioritized of our five study populations, despite real-time
385 news reports from multiple provinces showing that these communities had been
386 disproportionately impacted by COVID-19⁵⁵⁻⁵⁸. A common justification provided by KIs for these
387 provinces was that race-based data was not widely collected in Canada⁵⁹, which limited crucial
388 real-time evidence gathering on high-risk communities and regions.

389
390 Of the six provinces, only Nova Scotia and Ontario clearly prioritized Black communities in
391 published policy plans. They were one of very few exceptions to Nova Scotia's strict age-based
392 prioritization strategy. Both the scans and our KIs stated that the provincial government's
393 generations-long partnership building with African Nova Scotian communities was critical to
394 successful outreach⁶⁰. Early discussions with African Nova Scotian community leaders
395 highlighted the need for immediate and extensive prioritization of Black communities due to a
396 history of racism and the resulting lack of community trust in healthcare systems^{35,61}.

397
398 Although race-based data was not routinely collected in Ontario during the study period, the
399 province prioritized Black populations living in "hot spot" communities (determined by postal
400 code) for vaccination. Black scientists and medical experts working directly with the provincial
401 government and the City of Toronto strongly supported this decision by sharing real-time data
402 indicating that these "hot spot" communities were experiencing the highest rates transmission,
403 hospitalization, and death due to COVID-19^{58,62,63}. They further stated that vaccine hesitancy
404 was highest among Black people of African and Caribbean origins, data consistent with NACI

405 findings^{27,58}. However, KIs for Ontario were unclear whether Black populations living in non-“hot
406 spot” regions were prioritized for vaccination, highlighting this as a potential gap in
407 prioritization. One KI noted the following:

408 *“It is not just Black people in low socio-economic circumstances or hotspot*
409 *communities who are at risk. Black people in middle income suburbs are also*
410 *at risk because of the systemic racism that weathers the black body and*
411 *creates patterns of chronic conditions amongst Black people across Canada.”*
412 *- Key Informant from Ontario (ID 827)*

413
414 While the scans did not reveal justifications through published policy documents, KIs for the
415 other four study provinces provided insights into why Black communities were not listed in
416 their rollout plans. KIs for Alberta stated that race-based data was not available to justify a clear
417 need for prioritization. KIs from British Columbia stated that the province’s Black populations
418 comprised only approximately 1% of the overall population⁶⁴. KIs for Quebec asserted that not
419 all Black communities required early prioritization and considered them to be too heterogenous
420 in terms of risk to capture by race alone.

421
422 According to KIs, these provinces used an intersectional approach to attempt to reach Black
423 communities. Alberta prioritized groups that had higher risks of severe outcomes due to age or
424 underlying medical conditions, as well those experiencing a higher risk of transmission exposure
425 (e.g. essential workers). Quebec targeted refugees, immigrants, and essential workers for
426 vaccination because these groups demonstrated high rates of hospitalizations and deaths.

427 British Columbia prioritized geographic areas with higher percentages of immigrants and
428 refugees. Finally, KIs for Manitoba did not provide a rationale for why they did not prioritize
429 their Black populations, but they stressed that the provincial focused on racialized communities
430 more generally as an attempt to reach their Black communities.

431

432 *First Nations, Inuit, and Métis (FNIM) populations:*

433 Environmental scans and KI interviews showed that, of our study populations, the FNIM were
434 prioritized earliest in all provinces, which was consistent with NACI guidelines²⁵⁻²⁷ (Fig 1). The
435 most common justifications provided for prioritizing FNIM populations are listed in Table 3.

436

437 Provinces employed some interesting prioritization strategies to accelerate vaccination of FNIM
438 populations, given their respective local contexts. A few provinces (British Columbia, Manitoba,
439 Ontario) prioritized FNIM age groups that were 15-20 years lower, on average, than that of the
440 general population at any given point in time. KIs cited published data showing that the life
441 expectancy for FNIM was significantly lower (e.g. up to a 17-year difference in some studies)
442 than that of the non-Indigenous population^{65,66}. KIs for Manitoba shared that the province did
443 not directly prioritize remote and isolated communities in their rollout policy, which deviated
444 from NACI guidelines²⁶, but instead attempted to capture them indirectly through community-
445 based “hot spot” eligibility. In Nova Scotia, the government prioritized the Mi’kmaq First Nation
446 people first in another exception to their age-based prioritization rule. KIs explained that the
447 Mi’kmaq were the predominant Indigenous population in Nova Scotia. By targeting vaccination
448 efforts towards this population, they hoped to reach both remote and urban communities early

449 in the rollout. They also confirmed that any individual who identified as FNIM but who was not
450 Mi'kmaw would have to follow the standard age-based eligibility criteria implemented for the
451 rest of the province.

452

453 *Gaps in prioritization*

454 KIs for Alberta and Manitoba shared that excellent real-time scientific evidence existed for First
455 Nations communities (and for the Métis peoples, in the case of Alberta), clearly demonstrating
456 that that these communities experienced significant harms related to COVID-19. This data
457 served as critical justification for prioritizing these populations. However, similar data-sharing
458 agreements were not in place for the Inuit in Alberta, and for both the Métis and Inuit in
459 Manitoba. KIs stated that, unfortunately, there was insufficient risk data regarding these
460 populations for decisionmakers to justify early prioritization without it appearing as preferential
461 treatment. As a result, these communities were not prioritized until several months into the
462 rollout, after reviewing real-time data from other provinces, which impeded vaccination
463 progress at a critical stage of the rollout (see “Limitations of Data Availability” section below).

464

465 NACI guidelines recommended prioritizing urban FNIM for vaccination, as “systemic barriers to
466 accessing necessary supportive care for COVID-19 also exist in urban settings related to factors
467 such as poverty, systemic racism, and homelessness”²⁶. Yet, many provinces appeared to rely
468 mainly on age-based prioritization of all FNIM adults to capture this community, rather than on
469 directly prioritizing this important subgroup. KIs for these provinces justified their choice by
470 stating that they deemed risk to be higher in more remote territories than in intermediate or

471 urban communities. Other reasons given for prioritizing remote over urban settings were: (1)
472 the higher likelihood of severe health outcomes because of underlying medical conditions and
473 poor housing conditions in remote settings; (2) a stronger risk of uncontrolled transmission or
474 outbreaks because of challenges in enforcing isolation measures; and (3) reduced access to
475 specialized healthcare services if infected. Urban FNIM in Ontario were later added to the
476 rollout plan after strong advocacy from local FNIM community leaders^{67,68} (see “Limitations of
477 Data Availability” section).

478

479 *Essential workers in non-healthcare settings:*

480 All provinces prioritized essential workers in non-health related occupations in the second
481 phase of the vaccine rollout (around April 2021) after healthcare workers, which was consistent
482 with NACI guidelines²⁶ (Fig 1). KIs for the provinces frequently stated that this timeline was also
483 necessary because of the severe, country-wide vaccine shortages between January and March
484 2021. The scarcity and delivery delays constrained provinces to prioritize vaccinating only their
485 highest risk groups during those months⁶⁹.

486

487 Essential workers, whether referred to as “critical workers” (Manitoba) or “priority front-line
488 workers” (British Columbia), referred to a similar category of workers whose services could not
489 be completed from home. Provinces adapted essential worker categories suggested by NACI to
490 more accurately reflect critical services provided in their local contexts (Table 4). Provinces
491 generally agreed with the NACI assertion that essential workers, who often worked in crowded
492 conditions where public health safety protocols could not be maintained, had an increased risk

493 of COVID-19 exposure, and therefore should be prioritized^{27,70}. Further justifications for
 494 prioritization are summarized in Table 3.

495 **Table 4. Provincial definitions of essential workers in non-health related occupations.**

Province	Type of non-medical essential worker:
Alberta	<p>Phase 2C (Apr 12, 2021): healthcare professionals, educators and support staff, childcare and support personnel, staff working in congregate settings, shelter and correctional facility staff, meatpacking plant employees, caregivers of high-risk individuals, designated family/support persons of individuals in long-term care, and law enforcement officers (e.g. front-line policing, provincial sheriffs, firefighters, and border services staff)⁷¹</p>
British Columbia	<p>Phase 2 (Mar 15, 2021): agri-food production workers (food processing plants, farms, nurseries, greenhouses, large industrial camps)</p> <p>Phase 3 (Apr 2021): first responders (police, firefighters, emergency transport), K-12 educational staff, childcare staff, grocery store workers, postal workers, bylaw and quarantine officers, manufacturing workers, wholesale/warehousing employees, staff living in congregate housing at places such as ski hills, correctional facilities staff, and cross-border transport staff</p>
Manitoba	<p>April 21, 2021: police and firefighters aged 18+</p>

	<p>April 24: community-based eligibility (<u>hot-spots</u>) available for essential workers aged 18+ working in childcare, school settings, food processing facilities, gas stations, grocery stores, food service, public health, and workplace safety roles</p> <p>Mid-June for second dose</p>
Nova Scotia	<p>Phase 1: workers in the Department of Community Services facilities (e.g. adult residential centres, regional rehabilitation centres, residential care facilities)</p> <p>Phase 2: (a) workers in correctional facilities, shelters, and temporary workers' quarters; (b) workers involved in food security (e.g., large food-processing plant workers), frontline police officers; (c) migrant workers (e.g., truck drivers and rotational workers, excluding those travelling to and from New Brunswick).</p> <p>Not included in prioritization: teachers, grocery store employees, migrant workers</p> <p>Certain essential workers removed from prioritization list in Apr 2021: migrant workers (truck drivers, rotational workers) and agri-food processing plant workers.</p>
Ontario	<p>Not initially prioritized in rollout strategy, but later included in late Phase 2:</p>

	<p>* Highest-risk group (April 29) – cannot work from home: licensed childcare and educational workers who interact directly with children</p> <p>** Group 1 (May 6) – workers in critical essential services: school staff and workers; individuals responding to critical events (e.g., police, firefighters, etc.); inspection workers in a variety of fields (food, border, buildings, etc.); funeral workers; food and agriculture workers, migrant workers</p> <p>*** Group 2 (May 11) – remaining essential workers: essential (electricity, communications, etc.) and critical retail workers (grocery, postal services, passport services, financial services, etc.); courts and justice system workers; transportation, warehouse, and distribution workers; waste management workers; natural gas and mine workers; uranium processing workers; and veterinary service workers</p>
Quebec	<p>Priority Rank 9 (Apr 2021): agri-food production workers, primary and secondary school and daycare staff, daycare workers, public safety workers (e.g., firefighters, police officers, correctional officers), people who work in slaughterhouses, temporary foreign farm workers, mining workers in remote areas, and workers in community organizations part of the <i>Programme de soutien aux organismes communautaires</i> (Support program for community organizations, PSOC)</p>

	Not included in prioritization: grocery store workers and teachers
--	---

496

497 Provinces deviated from NACI guidelines in some notable ways due to local contextual factors.

498 Nova Scotia made another exception to its age-based prioritization strategy by prioritizing

499 essential workers who were not able to maintain public health guidelines effectively because of

500 the nature of their occupations⁵². However, certain NACI-recommended essential worker

501 categories were not included or were removed from prioritization (Table 4). According to KIs,

502 decisionmakers assessed that these subgroups would be vaccinated more efficiently through

503 age-based prioritization because of the province's small population size. In Quebec, grocery

504 store workers and teachers were not prioritized (Table 4). KIs explained that, due to limited

505 vaccine supply, Quebec prioritized older age groups followed by individuals at higher risk of

506 severe disease if infected. KIs indicated that decisionmakers found it difficult to justify

507 prioritizing occupations with younger average working ages, as they would likely have better

508 outcomes if infected over older individuals or those with underlying medical conditions.

509

510 *Individuals experiencing homelessness:*

511 As mentioned earlier, we were interested in how provinces prioritized shelter residents as well

512 as those with unstable housing situations. All provinces prioritized shelter residents in the

513 second phase of their vaccine rollout plans (Fig 1), consistent with NACI guidelines²⁷, with

514 justifications provided in Table 3. Notably, Quebec did not initially prioritize individuals

515 experiencing homelessness, but later included them in their revised policy plan released in

516 March 2021. KIs reported that night curfews implemented across the province to curb

517 transmission led to the unintended consequence of outbreaks in congregate settings such as
518 shelters. KIs for Nova Scotia confirmed that prioritization was based on age of shelter residents,
519 as was consistent with the general provincial strategy.

520

521 *Gaps in prioritization*

522

523 By contrast, individuals experiencing homelessness but not living in shelters were only
524 prioritized in two provinces: Alberta and Ontario (Fig 1). KIs for Alberta confirmed that they
525 intentionally defined individuals experiencing homelessness as ‘transient populations’ in their
526 published policy plan to include both shelter and non-shelter residents. However, it remains
527 unclear how well this was communicated to the public, as this definition was not explicitly
528 stated in their rollout plan. Ontario explicitly mentioned prioritizing individuals living in
529 encampments in Phase 2 (April 2021)⁷⁰. KIs for other provinces did not provide rationales for
530 overlooking this key subgroup, aside from admitting that it was a “hard-to-reach” population.

531

532 *Individuals with disabilities:*

533 As mentioned earlier, we focused on individuals facing significant barriers to vaccination, which
534 included those with developmental disabilities and those who were homebound with a
535 disability. Of all our study populations, individuals with disabilities had the most variability in
536 prioritization across provinces. Based on our findings, four provinces prioritized individuals with
537 disabilities in their original vaccine rollout plans (Alberta, British Columbia, Manitoba, Ontario),
538 adopting a tiered approach based on severity levels within this population (highest risk, high

539 risk, and at-risk)⁷²⁻⁷⁵. British Columbia followed NACI guidelines most closely by vaccinating
540 those in institutionalized care in Phase 2, followed by those who were clinically extremely
541 vulnerable due to their disability in Phase 3⁷⁶ (Fig 1). KIs for these provinces highlighted the
542 importance of real-time risk data in informing their early prioritization strategy, revealing
543 higher rates of hospitalizations, ICU admissions, death, and other severe outcomes among
544 individuals with developmental delays or intellectual disabilities compared to the general
545 population^{77,78} (Table 3). In fact, despite being initially excluded from prioritization, Quebec
546 later revised its rollout plan to include individuals with disabilities in April 2021 after reviewing
547 real-time risk data⁷⁹ (see “Data Informed Prioritization Strategies” below).

548
549 Notably, Nova Scotia intentionally did not prioritize individuals with disabilities, despite
550 evidence that Nova Scotia had a higher percentage of individuals living with a disability
551 compared to other provinces^{54,80}. KIs from Nova Scotia acknowledged the heightened risk
552 experienced by those with disabilities but once again cited that the province assessed that its
553 age-based rollout strategy would be more efficient at reaching this population than if they were
554 to prioritize those with underlying medical conditions.

555
556 *Gaps in prioritization*

557 Among provinces that prioritized individuals with disabilities, those who were homebound were
558 often prioritized later, if at all, compared to those in institutionalized settings. Information on
559 prioritization of homebound residents for vaccination was not easily available publicly, but KIs
560 for all provinces, except Alberta, provided some useful insights. For instance, homebound

561 individuals in Manitoba began receiving prioritization in June 2021 through the Community
562 Living Disability Services (CLDS), which provides services for individuals with both mental and
563 physical disabilities in the province. It was, however, unclear if homebound individuals not
564 eligible for CLDS received prioritization or transportation services. Ontario began offering
565 services to assist homebound individuals (both at-home services as well as transporting them to
566 vaccination sites) in Summer 2021, and Quebec included homebound individuals in their
567 revised plan in April 2021. Although Nova Scotia did not specifically prioritize individuals with
568 disabilities, KIs verified that government-initiated home vaccinations for individuals with
569 mobility issues became available in April 2021. Finally, British Columbia offered transportation
570 services for homebound individuals upon request, although no specific timeline was provided.

571

572 Objective 2: Identify contextual factors that influenced how provinces selected
573 priority populations for early COVID-19 vaccine access.

574 The prioritization of vaccines varied across provinces due to contextual factors specific to each
575 region. Factors such as population demographics and geography led to the realization that no
576 single approach, including those recommended by NACI, could be uniformly applied across all
577 provinces. Through KI interviews, three factors emerged as significant drivers for the selection
578 of priority populations and the corresponding timelines for early COVID-19 vaccine distribution:
579 Data Availability, Population Size, and Geography.

580

581 Data Availability

582 Data availability often influenced whom provinces chose to prioritize and when. Provinces
583 looked to data to determine how populations might be disproportionately negatively impacted
584 by COVID-19 or how they experience barriers to vaccine uptake. However, presence or absence
585 of data presented a dual role, either enabling the prioritization of key populations or preventing
586 certain populations from receiving vaccine priority despite their high-risk level.

587

588 Data-Informed Prioritization Strategies

589 The scarcity of vaccines and the severe health risks posed by COVID-19⁸¹ led to public concerns
590 and different groups requesting to be prioritized for vaccination⁸²⁻⁸⁵. KI interviews and our
591 environmental scans revealed that decision makers faced immense pressure when prioritizing
592 certain groups over others⁸⁴⁻⁹⁰. Data gave decision makers a seemingly objective and scientific
593 tool for answering questions such as identifying individuals most likely to contract COVID-19,
594 those facing barriers to vaccine accessibility, and those at higher risk of severe outcomes.

595

596 For instance, Ontario employed a data-driven approach by prioritizing individuals residing in
597 geographical “hot spot” communities, identified through historic and ongoing infectious disease
598 trends, as previously described⁹⁸. The province aimed to lower the disproportionate impacts of
599 COVID-19 on racialized urban populations, individuals living in multigenerational households,
600 and essential workers in non-healthcare settings through this approach^{91,92}.

601

602 Data-driven approaches also influenced the prioritization of First Nations groups across several
603 provinces. In Manitoba, for example, a KI highlighted that previous publications on the
604 disproportionate negative health impacts of the 2009 H1N1 Swine Flu pandemic on First
605 Nations^{93,94} were leveraged by the First Nations Health and Social Secretariat of Manitoba to
606 successfully highlight the disproportionate risk this community faced for negative COVID-19
607 outcomes. This knowledge informed the province's decision to prioritize First Nations groups in
608 early February, one of the earliest prioritized groups in Manitoba (Fig 1).

609
610 In Quebec, the decision to prioritize vaccination of individuals with disabilities evolved during
611 the rollout as a result of real-time scientific evidence. This group was not listed in the province's
612 initial rollout plan released in January 2021 because Quebec's Ministry of Health and Social
613 Services concluded that there was insufficient evidence of an increased risk of COVID-19
614 infection for this population⁹⁵⁻⁹⁷. KIs from Quebec verified this sentiment, explaining that the
615 Ministry initially found no evidence that vaccinating early would provide a noticeable benefit.
616 However, real-time scientific data that severe outcomes among individuals with developmental
617 delays or intellectual disabilities were higher compared to the general population proved
618 instrumental in changing the province's stance on prioritization^{77,78}. Quebec later revised its
619 plan to prioritize both individuals with disabilities living in group homes in March 2021 and
620 those living at home with families in April 2021⁹⁸.

621

622 Limitations of Data Availability

623 Data availability was, however, not equitable across all population groups in Canada. The
624 quality and quantity of data varied across population groups, leading to inequities in identifying
625 who required prioritization. Inconsistent data availability for Inuit and Métis populations in
626 Canada meant that these groups were not always prioritized when First Nations were, despite
627 knowledge that they experienced similarly high risk for barriers to vaccine access and negative
628 health outcomes⁹⁹. In Manitoba, while First Nations were prioritized as early as February 2021,
629 Inuit and Métis populations were not, despite experiencing similar disproportionate health
630 consequences during the pandemic⁹⁹. Key informants from other provinces reported similar
631 variations in prioritization for First Nation, Métis, and Inuit populations.

632

633 We had wonderful data demonstrating that First Nations people in Manitoba
634 were experiencing more significant harms related to COVID and at a much
635 younger age. We knew, for example, that First Nations people who died of
636 COVID were dying, on average, 17 years earlier than non-First Nations people.
637 That allowed us very early on to advocate to government to have a 20-year
638 age differential when it came to eligibility for the vaccine.

639 -Key Informant from Manitoba (ID 698)

640

641 Key informants revealed that First Nations organizations in Manitoba had established data-
642 sharing agreements and structures before the COVID-19 pandemic with the Manitoba
643 government. These agreements facilitated data access for the province, through the lens of

644 First Nations Principles of ownership, control, access, and possession (OCAP). OCAP are a set of
645 standards that ensure First Nations have authority over how their data is collected, used, and
646 shared, emphasizing self-determination and data sovereignty. These pre-established
647 agreements and structures allowed for data availability that facilitated vaccine prioritization for
648 First Nation groups. However, similar processes were not in place for Métis data in Manitoba.
649 Provincial representatives presented the lack of provincial data on Métis populations as a
650 reason why Métis and Inuit populations were not prioritized at the same time as First Nations
651 groups. After much advocacy from Métis groups, Métis and Inuit populations were eventually
652 prioritized in May of 2021¹⁰⁰.

653

654 ... the province said there wasn't sufficient data to suggest that Métis and
655 Inuit were experiencing significantly worse outcomes in terms of COVID
656 infection and outcomes associated with COVID for them to be included in the
657 prioritization. So, for Inuit, it was, "Well there's just so few." And then, Métis,
658 it was, "Well we don't have data to really tell us that their outcomes are
659 significantly worse than the general population." That was the nature of the
660 discussions a year ago when all this started.

661 -Key Informant from Manitoba (ID 613)

662

663 An interviewee from Alberta explained that these disparities in health data availability for Métis
664 populations stemmed from the Federal government's prioritization of data-sharing agreements
665 with First Nations, as they fall under Federal jurisdiction through the Indian Act. Métis people

666 do not fall under federal jurisdiction, despite being section 35 recognized (one of the three
667 indigenous peoples of Canada)¹⁰¹, resulting in Métis and Inuit people being left to navigate
668 agreements with their provincial health authorities without support from the Federal
669 government. In contrast, the Métis Nation of Alberta negotiated an information-sharing
670 agreement with Alberta Health in 2010, so all FNIM populations were simultaneously prioritized
671 for the COVID-19 vaccine.

672
673 Limited data availability on important FNIM subgroups also hindered the efficiency of the
674 rollout and impacted the trust between FNIM populations and provincial governments. As
675 mentioned earlier, urban FNIM were not explicitly prioritized in most provinces. KIs for Ontario
676 shared that the urban FNIM population was a critical subgroup that was missed due to a lack of
677 sufficient data on urban population size, risk, and the health inequities faced by this group. KIs
678 emphasized that the majority of FNIM peoples in Canada now live in cities yet were significantly
679 undercounted in the 2016 census (e.g. by a factor of 2 to 4 in a Toronto-based study)^{68,102}. They
680 explained that, since historic partnerships of trust with FNIM communities had not been
681 established prior to the pandemic, urban FNIM were considered “hard-to-reach” populations
682 for COVID-19 vaccination and were, therefore, not efficiently prioritized early on in the rollout.
683 Once again, strong advocacy from FNIM community leaders was required to include them in
684 the prioritization plan.

685

686 Population Size

687 Population size influenced vaccine rollout and prioritization strategies at both the
688 interprovincial and intraprovincial levels. Interprovincial population sizes refer to variations in
689 population across Canadian provinces, while intraprovincial population size refers to the
690 differences in size of population subgroups within a given province. These population sizes
691 played a crucial role in determining which groups were deemed feasible to prioritize and
692 shaped overall vaccine distribution strategies on a large scale.

693

694 Interprovincial Population Dynamics and Vaccine Rollout

695 Provincial population sizes influenced the perceived logistical benefits of implementing
696 prioritization strategies beyond age-based categories. All provinces prioritized their populations
697 based on age, the most significant risk factor for adverse COVID-19 outcomes and aligned with
698 NACI recommendations²¹. However, the differentiation among provinces was the additional
699 layers of prioritizations for certain groups apart from age. Some provinces considered their
700 population size too small to further specify and prioritize specific population groups. As
701 discussed earlier, KIs from Nova Scotia, for instance, revealed that the province determined
702 that focusing on age-based prioritization would be more efficient because of the narrow time-
703 spacing between age groups caused by the province's relatively small population. Decision
704 makers believed that introducing additional prioritized groups would require more time and
705 resources, whereas prioritizing solely based on age could be implemented more swiftly and
706 effectively.

707

708 Intraprovincial Population Variability and Prioritization Strategies

709 In the case of specific ethno-racial communities, such as Black populations, some provinces
710 found these subgroups too small in their province to justify targeting for vaccination. For Black
711 Canadians, this sentiment is reflected in the data. More than half (52.4%) of Canada's Black
712 population live in Ontario, followed by Quebec housing the second-largest population⁶⁴. While
713 the prairie provinces have witnessed a rapid growth rate among the Black population, provinces
714 like British Columbia experienced slower growth⁶⁴. Therefore, it is unsurprising that KIs from
715 British Columbia referenced small population size as a reason why Black populations were not
716 explicitly targeted, instead opting for community-based vaccine campaigns that targeted
717 racialized groups in areas known to have a higher proportion of racialized individuals, recent
718 immigrants, and refugees, referred to as Inclusion Groups. Additionally, the province focused
719 on healthcare frontline worker groups, recognizing the overrepresentation of racialized workers
720 in privatized healthcare settings. Conversely, in Toronto, a city in Ontario where 70.4% of
721 Ontario's Black population resides, there were Black-Led Vaccine Clinics, known as the Black
722 Health Vaccine Initiative, organized by the Black Physicians' Association of Ontario (BPAO) and
723 several other local Black healthcare organizations^{88,103}, with the goal of reducing barriers to
724 vaccine uptake. This was in addition to Black communities being targeted through "hot spot"
725 communities in Ontario.

726

727 Even when provinces did prioritize small population groups, health officials acknowledged that
728 it may have led to suboptimal outreach efforts. In British Columbia, for example, Inuit
729 populations were targeted for prioritization, despite making up less than 0.01% of the

730 population (0.6% of the FNIM population in British Columbia) in 2016¹⁰⁴. However, a KI stated
731 that outreach efforts were not as organized and effective as they could have been because of
732 the low representation.

733
734 Lastly, KIs noted that population size influenced the representation of certain population
735 groups in terms of their ability to advocate effectively to government. In the early stages of the
736 pandemic, several groups were prioritized because of their ability to gather, advocate, and be
737 heard. However, smaller subpopulations lacked the same numbers and resources to advocate
738 for prioritization or even recognition. For instance, when the Métis and Inuit were initially not
739 prioritized alongside First Nations in Manitoba, the Manitoba Métis Federation had sufficient
740 representation and resources to gather and advocate for their inclusion^{99,100}. However,
741 numerous other groups did not have had the same representation or resources.

742
743 *I sat three days a week with provincial chief medical officers of health in this*
744 *discussion and listened to other populations ... emergency workers, police, fire,*
745 *ambulance healthcare workers, teachers, others who came together and*
746 *lobbied very strongly to be identified as priority populations. The advantage*
747 *we had was the [First Nations] surveillance data. We could bring that to those*
748 *discussions and those tables on an almost daily basis. I presented it nationally*
749 *as well to say [that] this is what made our population different and that the*
750 *planned response needed to be different.*

751 *-Key Informant from British Columbia (ID 301)*

752 Geography

753 The geography of certain provinces also presented a logistical challenge in vaccinating and
754 providing care to the many remote communities within Canada. Canada is the second largest
755 country in the world by land mass, yet its land is largely uninhabited¹⁰⁵. Most people live in the
756 southern part of the country, near the American border¹⁰⁵. This vast geography, coupled with a
757 relatively small population, has led to the formation of many remote and isolated communities
758 that are hours, if not days, away from urban centres or resources. Some communities are so
759 remote that they require dog sleds, snowmobiles, and air services to transport medical supplies
760 from airports to the communities that need them¹⁰⁶.

761

762 Geographical isolation had divergent effects on provincial strategies for prioritizing remote and
763 rural communities during the early stages of vaccine rollouts. It either presented obstacles to
764 effective prioritization or provided a rationale for early prioritization.

765

766 In the early stages of vaccination, the COVID-19 vaccines available were delicate and required
767 ultra-cold storage conditions. In provinces with rural and remote communities lacking the
768 necessary infrastructure to transport and store vaccines under the required conditions,
769 providing vaccines to these communities became a challenge. Instead, these provinces focused
770 their attention on establishing vaccination centres within facilities that could appropriately
771 store and disseminate early versions of the COVID-19 vaccines. As a result, provinces like
772 Alberta and Manitoba faced limitations in effectively prioritizing remote and rural populations,
773 including on-reserve FNIM communities.

774

775 *The transportation issue had to do with the fact that these vaccines are fairly*

776 *fragile for transportation. They don't like to be agitated too much and they*

777 *like to be super cold. Those two things also meant that in the early days, until*

778 *we had the infrastructure in place to do good transportation, we had to limit*

779 *the number of places where you could provide the vaccine.*

780 *- Key Informant from Alberta (ID 672)*

781

782 On the other hand, KIs from other provinces referenced geographical isolation as a reason why

783 remote communities were prioritized. Due to their closed and isolated nature, a COVID-19

784 outbreak could spread quickly and limited access to specialized services and health resources

785 could result in severe COVID-19 related health outcomes. Thus, provinces like British Columbia

786 regarded geographic isolation as a driving factor for prioritizing vaccination efforts in remote

787 communities.

788 Discussion

789 Our findings highlight the use of multi-phased approaches by several provinces, many of which

790 tailored prioritization to their local contexts considering vaccine shortages. These adaptations

791 were driven by factors such as vaccine availability, population distribution, the quality of data

792 available, and the influence of community advocacy groups.

793

794 Multiple reviews highlight a dearth of scientific literature on strategies, interventions, and

795 factors influencing equity in COVID-19 vaccination¹⁰⁷. Our study contributes to this gap by

796 revealing, through our literature search and KI interviews, how provinces made context-driven
797 decisions that reflected the information at hand, the needs of their populations, and the
798 constraints they faced. However, there are key learnings that could be applied to allow for
799 more equity-driven future rollouts. These insights revolve around how data availability and
800 population size can influence prioritization, requiring provinces and territories to critically
801 consider how these two factors impact vaccine rollout.

802
803 Adopting a critical approach to understanding what data is available for decision-making, and
804 why, is crucial to avoiding perpetuated inequities resulting from data availability. This approach
805 entails an examination of the processes and factors that determine how and if data is collected,
806 including consideration of potential biases or exclusion of demographic groups from data being
807 published¹⁰⁸⁻¹¹⁰. Additionally, to combat the issue of a lack of data, health officials and
808 governing bodies could prioritize the collection of socio-demographic and race-based data¹¹⁰.
809 Historically marginalized groups are often the ones who face the negative repercussions of
810 insufficient population-specific data^{108,109,111,112}, such as the under-screening of Black Canadian
811 women for cancer despite evidence of their heightened vulnerability to worse outcomes¹¹¹.
812 Our findings echo this issue, revealing that inadequate data on populations led to limited
813 prioritization early in the pandemic. This challenge was exacerbated by a lack of political will to
814 bridge the data gap at the beginning of the pandemic through the collection of race-based data
815 at vaccination, prompting an open letter to the Government of Ontario advocating for race-
816 based data collection^{110,113}.

817

818 Similarly, data governance issues, particularly the absence of data-sharing agreements among
819 Métis groups, posed challenges to the prioritization of Métis populations in Alberta, Manitoba,
820 and Nova Scotia. When considering whether to prioritize Métis groups, and other historically
821 marginalized groups, based on available data, it is crucial to pause and inquire into why data
822 may be absent and what assumptions decision-makers might be making due to this data
823 gap^{99,108,112}. A further step would be to consider how these data gaps could be filled. Relying
824 solely on the data at hand for prioritization can be insufficient and potentially harmful, as it may
825 perpetuate established systemic forms of exclusion.

826

827 Interviews with KIs also underscore the influence of population size and geography on COVID-
828 19 vaccine rollout and prioritization in Canadian provinces. While all provinces prioritized based
829 on age, additional layers of prioritization were contingent on perceived feasibility, with some
830 provinces deeming their total population size too small to warrant further prioritization metrics
831 that went beyond age. However, only prioritizing based age could further marginalize already
832 disadvantaged groups. COVID-19 related hospitalization and mortality is disproportionately
833 higher among Black, FNIM, and other racialized communities^{114,115}. Additionally, these
834 populations tend to be younger^{64,116,117}. As a result, studies have indicated that COVID-19
835 vaccine prioritization based solely on age benefits older, white populations at the expense of
836 younger, Black, FNIM, and other racialized communities¹¹⁸.

837

838 Further, studies suggest that an effective vaccine prioritization strategy should adopt an
839 intersectional and dynamic approach^{29,119} that considers the proportion of susceptible

840 individuals in a community, including those more likely to contract the virus or who have not
841 been previously infected¹¹⁹. This approach would also consider individuals with multiple risk
842 factors, geographic and occupational risk exposures, and how interesting identities may affect
843 risk levels²⁹. An effective vaccine strategy should be adaptable, continually adjusting to the
844 evolving landscape of risk factors, exposures, and susceptibilities¹¹⁹. The size of populations also
845 impacted advocacy efforts, with larger groups having more resources and influence, as seen in
846 the prioritization of Métis and Inuit alongside First Nations in Manitoba due to the Manitoba
847 Métis Federation's effective advocacy. Smaller subpopulations faced difficulties in garnering
848 recognition and prioritization during the early stages of the pandemic. Moving forward, it
849 would be prudent to consider what populations may not be heard or prioritized because of a
850 lack of visibility or resources.

851

852 Strengths and Limitations

853 This paper offers a comprehensive examination of provincial prioritization plans and
854 justifications provided, aimed at ensuring equitable access to and uptake of COVID-19 vaccines
855 five key populations in Canada at high risk of negative outcomes and/or barriers to vaccine
856 accessing the vaccine. A major strength of our study is our direct engagement with key
857 decision-makers who played pivotal roles in shaping provincial vaccination policies and
858 strategies. By interviewing these individuals, we gained unique insights into the thought
859 processes, considerations, and challenges that informed the development and implementation
860 of vaccination plans at the provincial level.

861

862 While our research aimed to be comprehensive and representative of all Canadian jurisdictions,
863 there were limitations. First, our study focused on six provinces due to availability of published
864 documents during the study period, potentially overlooking valuable insights from excluded
865 provinces and territories. Nevertheless, we sought to encompass provinces with diverse
866 geographical, demographic, and linguistic characteristics to ensure a broader representation of
867 Canadian contexts. Second, we only interviewed a few KIs per province; therefore, the
868 perspectives gathered may not represent those of the entire province. However, we conducted
869 interviews until saturation was reached and aimed to capture a range of perspectives from key
870 decision-makers involved in vaccine rollout efforts. Third, while our qualitative interviews and
871 environmental scans aimed to capture all relevant strategies and interventions, it is possible
872 that some initiatives may have been overlooked if they were not publicly accessible when
873 environmental scans were completed nor mentioned by our KIs, despite our efforts to keep our
874 environmental scans as up-to-date as possible. Additionally, NACI guidelines and provincial
875 policy plan documents were regularly updated throughout the course of the rollout. This
876 proved to be challenging when asking KIs to recall prioritization decisions that were made at
877 the planning phase. To mitigate these challenges, our team regularly verified and recorded
878 policy updates by date during the study period.

879
880 Moving forward, future research endeavors should expand beyond the scope of this study to
881 evaluate the other four dimensions of the RE-AIM implementation framework for assessing
882 vaccine rollout initiatives, including effectiveness, adoption, implementation, and maintenance.
883 Moreover, the active involvement of priority populations in research design and interpretation

884 will be crucial for ensuring that future vaccination efforts align with the needs and perspectives
885 of diverse communities.

886 Conclusion

887 Our work delves into the equitable distribution of COVID-19 vaccines across six Canadian
888 provinces, revealing nuanced variations driven by factors such as vaccine availability,
889 demographics, and early community-led partnerships. It examines how provincial policies
890 allowed tailored local responses that addressed NACI's equity-informed recommendations. Our
891 research fills gaps in the literature by elucidating the context-driven decision-making behind
892 vaccine prioritization, emphasizing the need for expanded data availability to include socio-
893 demographic and race-based data. Our findings provide key learnings for equitable vaccine
894 distribution in future mass vaccination emergency situations in Canada and globally.

895 Acknowledgements

896 We extend our sincere gratitude to our key informants for sharing their invaluable time and
897 perspectives in this study. We also wish to thank the Implementation Science Trainee Cluster,
898 along with the professors and students at the Dalla Lana School of Public Health, University of
899 Toronto, for their mentorship and feedback, which were instrumental in shaping this work.

	Not prioritized
	Phase 1
	Phase 2
	Phase 3
	No defined phases

		January 2021	February 2021	March 2021	April 2021	May 2021
Black communities	Alberta					
	British Columbia					
	Manitoba					
	Nova Scotia	All African Nova Scotian communities (planning began in Feb; first vaccines administered in Apr)				
	Ontario	Ages 12+ in "hot spot" communities				
	Quebec					

		January 2021	February 2021	March 2021	April 2021	May 2021	
First Nations, Inuit, & Métis	Alberta	Remote and fly-in FN communities	FN or Métis aged 65+	FNIM aged 50+ (on/off reserve)	All FNIM aged 35+		
	British Columbia	Remote & isolated Indigenous communities	FNIM aged 65+; Elders & other community leaders	FNIM aged 18-64			
	Manitoba		First dose by age group: FN in remote communities and in urban centres (incl. Elders, Traditional Healers, & Knowledge Keepers)			All FNIM for second dose	
	Nova Scotia		Mi'kmaq and FN communities aged 55+, starting with Elders, Knowledge, and Language Keepers, followed by other Indigenous communities on- and off-reserve				
	Quebec		Rank 4: Adults aged 18+ of remote or isolated communities (added in revised plan released in March)
