# 28 Abstract

29

30	Isolation of patients with communicable infectious diseases limits spread of pathogens
31	but can be difficult to manage outside hospitals. Rwanda deployed a digital health
32	service nationally to assist public health clinicians to remotely monitor and support
33	SARS-CoV-2 cases via their mobile phones using daily interactive short message
34	service (SMS) check-ins. We aimed to assess the texting patterns and communicated
35	topics to understand patient experiences. We extracted data on all COVID-19 cases
36	and exposed contacts who were enrolled in the WelTel text messaging program
37	between March 18, 2020, and March 31, 2022, and linked demographic and clinical
38	data from the national COVID-19 registry. A sample of the text conversation corpus was
39	English-translated and labeled with topics of interest defined by medical experts.
40	Multiple natural language processing (NLP) topic classification models were trained and
41	compared using F1 scores. Best performing models were applied to classify unlabeled
42	conversations. Total 33,081 isolated patients (mean age 33.9, range 0-100), 44%
43	female, including 30,398 cases and 2,683 contacts) were registered in WelTel.
44	Registered patients generated 12,119 interactive text conversations in Kinyarwanda
45	(n=8,183, 67%), English (n=3,069, 25%) and other languages. Sufficiently trained large
46	language models (LLMs) were unavailable for Kinyarwanda. Traditional machine
47	learning (ML) models outperformed fine-tuned transformer architecture language
48	models on the native untranslated language corpus, however, the reverse was
49	observed of models trained on English-only data. The most frequently identified topics
50	discussed included symptoms (69%), diagnostics (38%), social issues (19%),

51 prevention (18%), healthcare logistics (16%), and treatment (8-5%). Education, advice, 52 and triage on these topics were provided to patients. Interactive text messaging can be 53 used to remotely support isolated patients in pandemics at scale. NLP can help 54 evaluate the medical and social factors that affect isolated patients which could 55 ultimately inform precision public health responses to future pandemics.

56

# 57 Author Summary

58

We present the first application of NLP for categorizing text messages between patients 59 60 and healthcare providers within a nationally scaled digital healthcare program. This study provides unique insights into the circumstances of home-based COVID-19 61 62 patients during the pandemic. Our trained topic classification models accurately 63 categorized topics in both English and African language texts. Patients reported and discussed both medical and social issues with public healthcare providers. This 64 65 approach has the potential to guide precision public health decisions and responses in future outbreaks, pandemics, and remote healthcare scenarios. 66

# 67 Introduction

68

The practice of isolating patients with communicable infectious diseases reduces transmission by separating infected individuals from healthy ones, and isolation at home allows healthcare systems to focus on managing severe cases in hospitals.<sup>1</sup> However, isolated patients may have changes to their condition that require attention from medical

professionals and can experience additional social stressors.<sup>2</sup> Isolation protocols have
even been considered a risk factor for mortality.<sup>3</sup> Understanding the complexity of
facility and home-based isolation remains a critical consideration in effective pandemic
response planning.

77

At the pandemic outset, the Rwanda government COVID-19 Joint Task Force adopted a 78 79 short message service (SMS)-based digital health service, WelTel, to remotely monitor and support community isolated cases and contacts of SARS-CoV-2 from the 80 centralized national command post. Its use continued throughout the emergency phase 81 of the pandemic as the key to their Home-Based Care (HBC) program.<sup>4</sup> The WelTel 82 platform was selected based on its history of use in HIV programs, prior clinic evidence, 83 and importantly, its accessibility.<sup>5–7</sup> Internet based tools and smartphone apps would 84 85 have been insufficient since, as a lower-middle income country (LMIC), only 23% of the Rwanda population has internet-access; yet at least 90% of the population has access 86 to cellular phones.<sup>8,9</sup> As in other applications of the WelTel platform, throughout the 87 COVID-19 response in Rwanda, automated 'check-in' messages were sent daily to 88 isolated patients, to which they could respond to report on their status and ask 89 90 guestions. A manually performed topic classification of WelTel text messaging 91 conversations with patients during HIV care previously demonstrated that these open-92 ended text messaging conversations contain wide ranging issues experienced by patients that could be acted upon.<sup>10</sup> 93

95	Advances in natural language processing (NLP) enables rapid computational topic
96	analysis (classification and modelling) which can delineate large amounts of text into
97	topics of interest. <sup>11</sup> Topic classification models using machine-learning (ML) have been
98	used in clinical settings to label text messages exchanged between healthcare
99	providers and outpatients, but never to our knowledge in a national scale program. <sup>12–15</sup>
100	Unfortunately, the uneven distribution of global healthcare data has the potential to
101	leave entire continents behind in the development of artificial intelligence (AI) for
102	healthcare." <sup>16</sup>
103	
104	In this study, we aimed to analyze the complete corpus of SMS conversations between
105	Rwanda's public health clinicians and isolated COVID-19 patients and contacts during
106	the first two years of the COVID-19 pandemic. We considered a clinical, social, and
107	logistical perspective using topic classification to better delineate the needs and
108	experiences of patients and the advice they were given, during isolation – a large-scale
109	approach that could be used to guide decision-making in outbreak management.
110	
111	
112	Results
113	
114	Participation in text messaging conversations

- 116 During the study period, Rwanda reported 131,190 cases of COVID-19, of whom
- 117 33,081 individuals (25%, 30,398 cases, 2,683 contacts) were registered in the WelTel

- 118 texting service. The numbers of patients registered, and the occurrence of text-message
- 119 conversations (with at least 3 interactive messages), appeared in waves similar to the
- 120 COVID-19 incidence reported in the national registry (Fig. 1).

121

122 Figure 1. COVID-19 case incidence, and enrollment and use of the WelTel SMS text

123 messaging service during the COVID-19 pandemic in Rwanda. The grey plot captures the 124 four major waves of case incidence in Rwanda. The red plot captures enrollment of COVID-19 125 patients (cases and contacts) in the WeITel system throughout the study period. Between June 126 and September 2020, patients were not being enrolled in WeITel as the Rwandan government 127 transitioned to government servers to host the software. The yellow and green plot captures the

number of patient-provider SMS conversations throughout the study period; most conversations
occurred in Kinyarwanda (67%) and English (25%) and other regional languages.

130

131	Of those registered, 6,021 patients (18%) used the texting service to generate 12,119
132	conversations (Table 1). Controlled for other demographic and clinical factors, the odds
133	of generating a conversation among females compared to males was 0.83 (95%CI:
134	0.78-0.89; p<0.001). Age did not significantly influence the frequency of conversations
135	(OR per year increase in age = 1.00, 95%CI: 0.99-1.00, p=0.17). Contacts were more
136	likely to generate conversations than cases (OR 1.83 95%CI: 1.63-2.06, p<0.001). The
137	proportion registered patients texting conversations varied across waves of the
138	pandemic (Wave one: 12%; two: 37%; three: 25%; and four: 3%).
139	
140	Table 1. Characteristics of COVID-19 patients (cases and contacts) and usage of the
141	WelTel text messaging service in Rwanda between March 18, 2020, and March 31, 2022.
142	Percentages are within group. A proxy is an individual who allowed another/other individual(s)
143	(e.g., a non-phone owner) to register for WeITeI using their phone number (e.g., a mother could

144 be a proxy for her non-phone-owning daughter). Shared refers to the individuals using a proxy

145 (e.g., the daughter).

146

The median number of conversations per patient was one (IQR: 1-2, range: 1-18), and
the median conversation length (# of discrete text messages) was three (IQR: 2-5,
range: 2-44). Most conversations occurred in Kinyarwanda (8,183, 67%) or English
(3,069, 25%), however other regional languages (French, Kiswahili, Ganda,
Chewa/Nyanja) were also identified (<10%). Language proportions were similar to the</li>
proportion of the population considered literate in those languages in Rwanda.<sup>27</sup>

#### 154 Comparison of NLP model performance

155

The NLP models tested classified most topics with a level of performance above our cut-off F1-score (Table 2). The traditional ML models performed better than fine-tuned transformer models on untranslated native language conversation data. Best performing models for each topic met the pre-determined F1-score cutoff of 0-7 for six of the nine

- 160 topics meeting the sample size threshold of 100. Model performance was roughly
- 161 correlated with the number of occurrences (within sample) of the given topic.
- 162
- 163 Table 2. Performance of classification models on original language (untranslated),
- 164 and English-translated conversations for each topic of interest. Blue and orange fill
- 165 indicate traditional-ML, and transformer architecture language models, respectively. Bold text
- 166 indicates an F1 score meeting our performance cutoff (≥0.7). Topics are ordered by best-
- 167 performing model F1 performance score (descending) when trained with original language
- 168 (untranslated) conversations as ultimately used to label the full corpus.

169

- 170 In our language experiments, fine-tuned transformer models generally performed better
- 171 when using the English (translated) training and testing corpus, exceeding the F1
- 172 threshold in all but one topic.

173

## 174 **Topic analysis of conversations**

- 176 Human labeling (training corpus) and machine topic labeling (full corpus) identified the
- topics and subtopics of interest at roughly similar frequencies (Figure 2 and S3 Fig).

178 Overall, medical topics were discussed more frequently than non-medical topics. The 179 most frequent topic was symptoms (69%), the majority reporting a lack of symptoms (59%). Diagnostic methods (38%, e.g., receiving COVID-19 test results), prevention 180 181 (18%, including non-pharmaceutical such as how to maintain isolation, and pharmaceutical such as vaccines), healthcare logistics (16%, e.g., asking where to get 182 tested), and treatment (8%, including management of symptoms). Social topics (19%) 183 184 included mention of culture or religion (5.5%), followed by discussing friends and family 185 (4.9%). Manually labeled training data revealed important issues such as nutrition and 186 food security (3.7%). Examples of text conversations are provided in Table 3.

190 complete corpus (n=12,119) based on both human- (n=2,791) and machine-

- 191 **labelling (n=9,328).** Note: conversations were often labelled with multiple topics/subtopics
- 192 therefore proportions do not sum to 1. Some topics did not have sufficient data to produce
- 193 models, or the models developed did not meet our performance cutoff of F1≥0.7. For these, the
- 194 proportion estimates are based upon human labelling alone.
- 195
- 196 Comparing the odds of topic discussion within the full corpus by patient demographic
- and clinical factors revealed minor differences that are reported in (S4 Fig).
- 198
- 199 Table 3. Illustrative text conversations excerpts between public health officials

#### and patients (cases and contacts) during the COVID-19 pandemic in Rwanda. "..."

- 201 indicates excluded text for brevity. Message types include: '(S):' a 'system' message
- 202 containing customizable content with automated sending; '(P):' a 'patient' message containing
- 203 patient remarks in free text form; and '(C):' a 'clinician' message containing clinician remarks
- in free text form.

CONVERSATION TOPIC	EXAMPLE
Reporting a lack of symptoms	<ul> <li>(S): Hello, how are you today? Do you have any symptoms of coronavirus? [alongside Kinyarwanda and French translations of the message]</li> <li>(P): We are ok. We do not have symptoms.</li> <li>(C): Hello! We inform you that you were tested negative for cornavirus. Thank you.</li> </ul>
Reporting symptoms	<ul> <li>(S): Are you OK (Yes/No)? Or tell us if you have new symptom [alongside Kinyarwanda translation of the message]</li> <li>(P): Good morning. I am coughing and I have flu but my situation is not alarming. I do not think that there is a problem.</li> </ul>

	(C): Thank you for informing us. Explain your situation to the Doctor
	who is in charge of calling you. He is going to call you soon.
	(S): haven't heard from you yet. how are you? [alongside
	Kinyarwanda translation of the message]
	(P): Good morning. My name is #NAME#. I have been suffering
	from COVID-19 for days, but yesterday I went at #HEALTH
	FACILITY# to have a medical test for checking. Till now I have
Diagnosis	not yet got results via an sms. Can you help me to get those
	results if possible?
	(C): Good morning. We will inform people in charge to help you. Be
	patient.
	(C): #NAME# please note that you tested Negative on COVID-19 Ag
	RT on 2021-01-25. Code :********
	(S): Check-in message
	(P): "I took a Doliprane. Because I have little fever. 37.4"
Treatment	(C): "Nice to hear that you are doing well.Doliprane helps for fever,
	body aches and headache"
	(P): Yes, Thank you! Have a nice day
	(S): Check-in message
	(P): "Can you tell me where people suffering from heart issues
	and other diseases can go to get a vaccine?"
	(C): "Where do you usually go for a medical follow up?"
Pharmaceutical prevention	(P): "…#HEALTH FACILITY#"
	(P): I suffered from Covid 19 a month ago but now I am healthy.
	(C): You can contact them in order to know what they have
	scheduled for you.
	(P): Thank you
Non-pharmaceutical	(P): "[Our] child has already tested positiveI have some

prevention	questionsWill not I be infected again once I share the same
	room and equipments with my child?Is it possible to get a
	medical test for checking before ending 14 days of
	quarantine?"
	(P): "I am still suffering from coughing while the medicine I
	was taking is over"
	(C): "It is a must to go for a medical test for checking after 14 days.
	It would be better to clean your hands neatly, and to put on mask
	accordingly before taking your child "
	(P): Thank you very much.
	(P): "I am suffering from COVID-19 and I live alone. I am
	starving and I don't have food. What can you help me? Thank
Social – food and nutrition	you for your helpful answer."
	(C): Good afternoon. You can call the head of your village for a help.
	Food aid is being distributed these days. Thank you.
	(S): Check-in message
Social outure and religion	(P): We are well this morning. We are really under the protection
	of Jesus.
	(C): That is good if you are well. Have a nice day.
	(S): Check-in message
	(P): Hello. I am pregnant and I have tested positive for COVID-19.
Matarnal & child health	At the beginning I did not have any symptoms, but now I have
	many and I need your advice.
	(C): "Be patient, you are going to get our support via a telephone
	call."
	(C): Hello, do you have any health or COVID related concerns you
Gratitude	would like to share with us today?
	(P): I tested negative for Covid 19. Thank you.

	(P): Thank you for your regular care.
	(P): Your advices are very important and we will always resort to
	them.
	(S): Check-in message
	(P): We are in a very bad situationWe are mixed with people
	who have symptoms and those who do not have them, and we
Safety concern	share the same bathroom and shower. Please, help us to get out
	of this situation before being infected.
	(C): Thank you for informing us. We are following up your situation.
	Keep on informing us. Thank you.
	(S): Check-in message
	(P): Good morning. All of us, including children, are well. We
Proxy example	don't have a problem. We hope to recover soon. Have a nice
	day. Thank you.
	(C): Thank you and have a nice day too.

206

# 207 Methods

208

### 209 Setting and digital health monitoring technology

210

211 Rwanda, a Central African nation with a population of 14 million, was internationally

- recognized for its prompt response to the COVID-19 pandemic.<sup>17</sup> Their public health
- command implemented the WelTel text messaging service [www.weltelhealth.com] on
- March 18, 2020, coincident with detecting its first COVID-19 cases. This tool enabled

public health staff to remotely monitor and support individuals who tested positive for, or
were at high risk of contracting, SARS-CoV-2, and remained operational until the public
health emergency was officially declared over.

218

219 The WelTel platform is a secure web-based application that healthcare providers can

access from any internet-connected device. It interfaces with cellular networks enabling

it to send both pre-set and manually input SMS messages to registered mobile phone

users. It features a conversation dashboard that visualizes responses.

223

224 Following the initial facility-based guarantine of COVID-19 cases identified at border 225 entry points, Rwanda launched its HBC program when community transmission became 226 widespread. Under this program, mild cases and contacts were asked to stay home and 227 be remotely monitored. Patients with significantly worsening clinical status were triaged 228 to hospitals. Individuals were enrolled as 'cases' if they tested positive for SARS-CoV-2 229 or as 'contacts' if they were deemed high risk due to exposure. Patients without 230 personal cell phone numbers were registered via a household member, friend, or 231 neighbor.

232

The messaging protocol for COVID-19 monitoring involved sending bulk automated daily 'check-in' texts in Rwanda's principal languages (Kinyarwanda, English, French) daily to registered patients throughout their isolation period. Patients could respond via text in their own words to indicate their status and/or ask questions. Replies indicating a problem or question were flagged for follow-up. Public health clinicians responded to

- 238 flagged messages to provide information or advice, forming interactive text
- 239 conversations.
- 240

#### 241 Included datasets and description

242

243 Patient registration and all text communication data generated between March 18, 2020 244 and March 31, 2022 was exported from the WelTel database and linked to the Rwanda DHIS2 COVID-19 testing registry to obtain missing demographic or clinical data.<sup>18</sup> 245 246 Personal identifiers were removed. For the purposes of our study, a 'conversation' was 247 defined as a text exchange consisting of at least one 'incoming' patient message 248 containing three or more words (filtering out minimal replies e.g., 'doing well'), together with at least one 'outgoing' public health clinician or automated system message (thus 249 250 being interactive). Patient registration and numbers of conversations and their 251 characteristics (# messages, language used) were quantified. Conversation usage was 252 compared across patient sociodemographic and clinical characteristics (sex, age, 253 province of residence, pandemic wave, and COVID-19 status (case vs. contact)) using 254 a multivariable logistic regression model. Odds ratios (OR) are reported with 95% confidence intervals (CI) and p < 0.05 was considered significant. Example conversations 255 256 were selected to illustrate context.

- 257
- Language translation and topic labelling
- 259

260	A list of topics and subtopics was developed through a three-round mini-Delphi process
261	involving ten public health experts, clinicians, and researchers from Rwanda and
262	Canada. This list was an expansion of a previously published list focused on clinical
263	care and used to develop a conversation analysis and visualization tool, ConVIScope. <sup>12</sup>
264	The final list of topics and subtopics encompassed perspectives on public health,
265	emergency response, and clinical care. Topic definitions are provided in (S1 Fig).
266	
267	For the purpose of labeling a training dataset for topic classification models, a sample of
268	2,791 text conversations from March 18, 2020, to May 31, 2021, was extracted from the
269	study period corpus. These conversations were analyzed for language use with
270	Google's CLD2 language detector. Non-English sample messages were translated into
271	English by a compensated professional healthcare text translator proficient in
272	Kinyarwanda, English, French, and Kiswahili.
273	
274	The English-translated conversations were labeled by at least three trained members of
275	the research team using a custom conversation annotation tool. Any conflicts in labeling
276	were resolved by an external team member. The topic labels were then applied back to
277	the corresponding conversations in their original language, where applicable.
278	

# 279 Classification model training, testing, and application

- 281 We aimed to identify the best performing classification model for each topic and
- subtopic. Training set sample size constraints limited our classification experiments to

topics with ≥100 occurrences. We employed the binary relevance strategy, which 283 284 simplifies performance management by building a separate binary classifier for each 285 topic. We experimented with both traditional ML algorithms and Transformer-based 286 language models for each topic. We explored large language models (LLMs, e.g., GPT-287 4), however, our literature review revealed that, of the three pre-trained with any 288 Kinyarwanda, the pre-training datasets for these models contained minimal 289 Kinyarwanda text (≤0.01%). Investigations of the performance of these LLMs at NLP tasks in Kinyarwanda suggested they were insufficient to include.<sup>19</sup> 290 291 Traditional-ML classification models: For training traditional ML models, we explored 292 five feature sets: binary and non-binary bag of words, TF-IDF (term-frequency inverse 293 document frequency), and character n-gram (with/without TF-IDF). The character n-

gram features were tried because Kinyarwanda is an agglutinative language. All

295 combinations of one of these feature sets, and one classification algorithm, were tested.

296 We evaluated logistic regression, ridge classifier, and random forest as classification

algorithms. Hyperparameters for each classifier were tuned using random search in
 five-fold cross validation.<sup>20</sup>

*Transformer-Based Language Models*: We leveraged open-source pre-trained
 Transformer-based language models for Kinyarwanda, including AfriBERTa, AfroLM,
 AfroXLMR, and KinyaBERT.<sup>21–24</sup> To fine-tune these models for our task, we employed
 the AdamW optimizer along with the binary cross-entropy loss function. Additionally, we
 incorporated dropout layers (with a probability of 0.0 for the first layer and 0.3 for
 subsequent layers) for regularization.

305

306	We compared the performance of each model for each topic using the validation set F1-
307	score, with a minimum F1-score cut-off of 0.7. The highest F1-score models were
308	applied to predict topics for the remaining 9,328 unlabeled, untranslated SMS
309	conversations.
310	
311	Additional Language experiments: Since our corpus contained a mix of high- and low-
312	resource languages (e.g., English, French, Kinyarwanda) we explored how this might
313	affect performance of the models by conducting identical experiments to above using
314	only the English-translated version of the training corpus. We evaluated both traditional
315	ML models (as above), and English pre-trained Transformer models (BERT,
316	Longformer). <sup>25,26</sup> F1 scores are reported for comparison.
317	
318	See (S2 Fig.) for more hyperparameter and fine-tuning details.
319	
320	Topic analysis and statistics
321	
322	Counts and proportions of conversations containing each topic (full corpus), and
323	subtopic (sampled corpus), are provided. Topic frequencies were compared by patient
324	demographics and clinical metrics using multiple independent multivariable logistic
325	regression models for each topic. Models incorporate all patient demographic and
326	clinical characteristics and use complete cases. OR are reported with 95% CIs and p-
327	values are adjusted for multiple testing using the Benjamini-Hochberg correction with a
328	false discovery rate of $0.05$ . Classified topic categories could be batch filtered and

manually read to understand the nature of the discussions that occurred within each
 topic.<sup>12</sup> Data summarizations, visualizations, and statistical testing were produced or
 conducted using R version 4.2.1.

332

## 333 **Discussion**

334

335 To our knowledge, this is the first study to report on the use of NLP to investigate a 336 broad range of topics from a complete corpus of conversational texts with patients in 337 home isolation in a pandemic or outbreak setting at large scale. Through a combination of manual annotation and NLP techniques, we gained insights into patient experiences 338 during COVID-19 in Rwanda by identifying key discussion topics between patients and 339 340 public health clinicians. The sustained use of the text messaging service in Rwanda 341 demonstrated the feasibility of using SMS-based communication for remote monitoring 342 at scale in a region with limited internet access but widespread mobile phone 343 penetration. Leveraging existing infrastructure allowed for efficient support for isolated 344 individuals, regardless of location or access to healthcare facilities.

345

Our data captured the first two years of the Rwandan COVID-19 pandemic, including text conversations in Kinyarwanda, English, and other local languages with public health clinicians to report their status or seek advice. Topic classification revealed that medical topics, such as symptoms, diagnostics, prevention, and treatment, were commonly discussed, reflecting patient's primary focus on their health status and obtaining medical guidance. However, social and lifestyle topics, including discussions about social

352 support, healthcare logistics, diet/nutrition, finances, and service quality, also emerged 353 as important aspects to patients during home isolation. The data underscores the need 354 for holistic support systems for patient isolation programs. Additionally, while our topic 355 classification approach rapidly quantified prevalent topics well, reflecting their relative 356 importance to patients, it also enables the sorting of large datasets into smaller 357 categories for easier manual evaluation by decision-makers. The identification of less 358 common topics, such as food insecurity, may also provide actionable targets for public 359 health responders, especially if it can be localized to communities.

360

NLP techniques are rapidly being introduced into health systems to understand 361 362 unstructured data from large datasets, such as clinical notes in electronic medical records (EMRs), social media posts, or free-text survey responses.<sup>11</sup> For example, topic 363 364 classification has been employed to sort unstructured patient feedback from text messages.<sup>15</sup> Still, manual gualitative analyses dominate. A manually labeled thematic 365 366 analysis of 1,454 patient portal secure messaging conversations between cancer patients and health professionals in the US during COVID-19 found 26% of 367 conversations were related to COVID-19 and identified topics related to changes in care 368 plans, symptoms, risks, precautions and symptoms.<sup>28</sup> In Northern Thailand manual topic 369 370 classification of SMS exchanges with 213 home-isolated patients with diagnosed 371 COVID-19 revealed several complexities of care including discussing symptoms or vital signs, medications, diet and exercise, mental stresses, information about COVID-19, 372 and a high proportion of logistical assistance to navigate the health services.<sup>29</sup> Manual 373 374 labeling is resource intensive and generally limited to smaller data sets. One US-based

study used NLP techniques to determine if patient-initiated secure messaging via a
EMR portal was associated with positive testing, but this was a simple binary
classification.<sup>13</sup> To our knowledge, our study is the first to use NLP techniques to
classify patient clinician texts into broad medical, social and logistical topics set by
experts, and at a national scale.

380

381 Our study compared performance of several ML model approaches. Traditional ML 382 models and transformer-based language models were both effective in classifying text message conversations into the predefined topics. While traditional ML models 383 performed better with untranslated conversations, transformer models had superior 384 385 performance when trained on English (translated) data, highlighting their limited performance on African languages.<sup>30</sup> This observation is consistent with the knowledge 386 387 that transformer architecture language models are likely to underperform on NLP tasks in low-resource languages until sufficient high-guality pre-training data is sourced and 388 leveraged.<sup>31</sup> Similarly, LLMs, which are also based on transformer architecture, 389 390 currently contain too little, if any, training on Kinyarwanda and other low-resource languages to be useful in our context.<sup>19</sup> A brief trial using Google Translate to machine 391 translate Kinyarwanda text into English for our study was inaccurate. This highlights the 392 393 importance of considering language-specific model performance when analyzing multilingual text data.<sup>32</sup> Language consideration remains a significant challenge, with 394 395 over 4,000 written languages worldwide. Pandemics affect everyone and AI tools must account low-resource languages to be equitable. 396

397

398 Our study has limitations. First, the supervised learning approach required the pre-399 definition and manual labeling of topics of interest which can be human resource 400 intensive. Furthermore, the topics of interest or training samples annotated may evolve 401 over time or change in different settings requiring continuously updating training 402 datasets. For example, prevalent discussions of vaccines came later in the pandemic 403 after most of our training data had been annotated. Including unsupervised ML models 404 that discover topics as they emerge could help overcome this bias, but have their own 405 flaws. Furthermore, while our dataset was similar in size to those used to train other 406 topic classification models in healthcare, many subtopics of interest were not prevalent 407 enough to develop models. Additionally, the training dataset was translated into English 408 for labelling purposes, again, being resource intensive and potentially altering meaning 409 in translation. Finally, training the models took time and conducting the NLP analyses 410 afterwards meant the data was not available to decision-makers real time. Ideally, once 411 models are trained and validated, they could be applied while an outbreak or pandemic 412 is occurring and provide insights into patient and population issues that could be responded to while they are occurring. Together with location data, this type of analysis 413 414 could contribute to precision public health responses.

415

### 416 **Conclusion**

417

418 Moving forward, future research should explore ways to further optimize the evaluation

419 of text-based communication for greater insights into the patient care journey in

420 pandemics, and clinical care. It must consider technology infrastructure available to

421	populations globally and be inclusive of resource-limited languages. <sup>33,34</sup> Efforts to
422	improve language support and translation capabilities across diverse linguistic and
423	cultural contexts will be essential to ensure equitable access to digital services by
424	people in all regions. Ultimately, emerging research on models that detect, understand,
425	and generate natural language, as well as development of tools that formulate
426	predictions and recommendations for healthcare decision-makers, will achieve the
427	higher accuracy, precision, and reliability required for use in routine healthcare.

# 551 Supporting Information

- 552 **S1 Figure.** Defined topics and subtopics of interest were determined by a Delphi process
- 553 contributed by expert members of the study team and incorporated into a bespoke annotation
- 554 software used to label conversations.

Торіс	Subtopic	Definition and Examples
	Physical	Any physical symptom, sensation, or feature (pleasant and unpleasant) that is mentioned in the conversation. Examples: pain, weight loss, burning, fatigue, shortness of breath,
		fever, diarrhea, muscle aches, cramping, coughing, bleeding, broken arm etc.
Symptoms		Any mental/emotional feeling, sensation, or feature (pleasant and
	Mantal / Emotional	unpleasant) that is mentioned in the conversation.
	Mental / Emotional	Examples: confusion, depression, fear, anxiety, low energy, extreme mood, suicidal ideation, feelings of guilt, lack of interest, stigma etc.
	No Symptoms	Patient explicitly mentions not having symptoms. Examples: I have no symptoms, I feel fine.
		The process of identifying a disease, condition, or injury based on
	Clinical	the signs and symptoms a patient is having and the patient's health
		history and physical exam.
		Discussion related to tests on blood, urine, or other tissues or
		substances taken from the body to help diagnose disease or other
Diagnostic Methods	Laboratory/Testing	conditions, whether performed or not.
		Examples: blood tests (CBC, FBG, Hb1Ac, TSH, lipid panel, etc.),
		blood cultures, urinalysis, pulmonary function tests, biopsies, stool
		test (FIT, FOBT), etc.
	Imaging	Studies that provide a picture of the body's interior to help diagnose

		disease or other conditions.
		Examples: x-ray, CT, MRI, fMRI, ultrasound, PET scan, etc.
	Other	Other diagnostic methods/topic(s) not listed.
		Pharmaceutical drug that usually requires a medical prescription to
		be dispensed.
	Medications	Examples: antibiotics, antidepressants, anti-hypertensives, amoxicillin, escitalopram, ramipril, etc. include over-the-counter
		medications (e.g., Tylenol)
	Procedures	Surgery, Breathing procedures, Radiation Therapy etc.
	-	Non-traditional method of healing/treating disease/condition.
	Alternative	Examples: herbal medicine, acupuncture, massage therapy, naturopathy, meditation, etc.
		Care that aims to ease pain and helps function, move, and live
Treatment (Rx)		better.
	Physical Therapy	
		Examples: physiotherapy (geriatric, neurological, orthopedic,
		chiropractic etc.)
		Giving advice/coaching/making recommendations to the patient
		(can be non-health related).
	Counselling	Examples: psychologic counseling, coaching of lifestyle modifications like diet beyond standard clinical advice (e.g., in-depth discussion on how to reduce salt intake, not simply saying to reduce salt), smoking cessation, the importance of exercise on cardiovascular health, etc.
	Other	Other treatment topic(s) not listed.
Prevention	Pharmaceutical	Any mention of an intervention that utilizes chemical or biological

Prevention methods given to or taken by humans in an attempt to	prevent
disease.	
Examples: prophylactic medications, immunizations, tr	eatment as
prevention, etc.	
Any mention of an intervention that does NOT rely on the second s	oio/chemical
products given to or taken by humans in an attempt to	prevent
disease. Especially those methods that are behavioura	al (ex:
physical distancing) or structural (ex: laws or policies).	
Provention	
Examples: personal protective equipment (e.g., maskir	ng), physical
distancing, barriers, quarantine/isolation, lockdowns, se	chool
closures, education programs, policies, laws, testing w	ithout
treatment, environmental decontamination, animal/pes	t control, etc.
Mention or pertaining to setting up or attending outpatie	ent clinical
care or diagnostics.	
Outpatient	
logistics/scheduling Examples: clinic, family doctor office, ECG appointment	nt,
hemodialysis appointment, dentist appointment, specia	alist
appointment, physiotherapy, etc.	
Mention or pertaining to any admission or stay in hospi	ital.
Receiving medical treatment during hospital admission	1.
Hospitalization	
Examples: visit to emergency department, or regarding	g planning,
admission, or discharge from hospital care. Includes lo	ong-term care
facilities.	
Relating to food/liquid intake and health.	
Lifestule/Debovioural Dist / Nutrition	
Examples: nutrition related to weight management, app	ple, fruits, pie,
sandwich, water, Coca-Cola, dinner, lunch, waffles, chi	ips, popcorn,

Exercise       Relating to physical activity done to improve health and fitness.         Exercise       Examples: working out, going to the gym, jogging, playing soccer, playing basketball, doing yoga, walking, walking the dog, etc.         Relating to the use of drugs or alcohol, and includes substances such as cigarettes, illegal drugs, prescription drugs, inhalants, solvents, etc.         Substance Use       Examples: alcohol, marijuana, tobacco use, fentanyl, ecstasy, cocaine, addiction of substances etc.         Other       Other lifestyle topic(s) not listed.         Other       Examples: "living at home currently," "bought a new house," "moving into an apartment in Victoria," "can't afford a place,"" "got evicted," "am homeless".         Nealing to work or school.       Relating to work or school.
Exercise       Examples: working out, going to the gym, jogging, playing soccer, playing basketball, doing yoga, walking, walking the dog, etc.         Relating to the use of drugs or alcohol, and includes substances such as cigarettes, illegal drugs, prescription drugs, inhalants, solvents, etc.         Substance Use       Examples: alcohol, marijuana, tobacco use, fentanyl, ecstasy, cocaine, addiction of substances etc.         Other       Other lifestyle topic(s) not listed.         Housing       Examples: "living at home currently," "bought a new house," "moving into an apartment in Victoria," "can't afford a place,"" "got evicted," "am homeless". Relating to work or school.       Relating to work or school.
Other       Relating to housing, shelter.         Housing       Examples: "living at home currently," "bought a new house," "moving into an apartment in Victoria," "can't afford a place,"" "got evicted," "am homeless".         Relating to work or school.
Housing       Relating to housing, shelter.         Housing       Examples: "living at home currently," "bought a new house,"         "moving into an apartment in Victoria," "can't afford a place,"" "got evicted," "am homeless".         Relating to work or school.
Housing       Examples: "living at home currently," "bought a new house,"         "moving into an apartment in Victoria," "can't afford a place,"" "got evicted," "am homeless".         Relating to work or school.
Housing       Examples: "living at home currently," "bought a new house,"         "moving into an apartment in Victoria," "can't afford a place,"" "got         evicted," "am homeless".         Relating to work or school.
"moving into an apartment in Victoria," "can't afford a place,"" "got         evicted," "am homeless".         Relating to work or school.         Wark/School
evicted," "am homeless".       Relating to work or school.
Relating to work or school.
Work/School
Work/School
Examples: "studying psychology," "UBC," "lots of studying to do,"
"stressed from exams," "I'm a banker," "work was so busy," "got
fired," etc.
Relating to government services provided for the benefit of the
community, such as education, medical care, and housing
programs.
Social Services
E.g.: family benefits, welfare, income assistance, housing
assistance, food subsidies, foster care, disability support, mental

		health services, etc.		
	Friends & Family	Relating to friends and family relations. E.g.: "went to see my mom," "spent time with friends," " hiking with		
		my partner, Tamily dinner, hung out with my best mend,		
		Relating to ideas and customs of a culture.		
		Examples: "Chinese herbal medicine," "fasting for Ramadan,"		
	Cultural/Religion	"sweat lodges," religious and spiritual practices, cultural institutions		
		their culture, refusing conventional treatment because of what is		
		taught in their culture.		
		Mention or related to transportation and or travel.		
	Travel	E.g., vacation in Mexico, work abroad, traveled to… I'm currently in		
	Dhyreicel	Mention or pertaining to the climate or physical environment.		
	Environment/Climate	E.g., smoke from fires, sun exposure, cold related illness, concerns		
		re logging or farming practices		
	<b>_</b>	Mention or pertaining to personal or other finances.		
	Financial	E.g., cost of something, affordability, economics.		
	Other	Other social topic(s) not listed.		
		An attempt that addresses the patient's problem within the context		
Service Quality	Problems Solved	of one conversation, regardless of if it was ultimately effective, but		
		at least addressed/attempted to address a present issue		
	Grateful Patient	Demonstration of gratitude toward the HCP or care provided.		

		Examples: Thanks! (if appears as genuine gratitude, beyond routine customary formalities). I really appreciate. (NOT: See you later, thanks!)
	Service Complaint	Conversation contains any concern or complaint brought forward about the care one is receiving, even if it also contains positive mentions.
	Request to Stop	Select this box if, at any time, the patient requests to be removed from the messaging platform or stop receiving messages.
Safety Concerns	No Subtopics	Discussing worry or concern about their life or the life of others based on specific circumstances. Example: I am worried about quarantining in a healthcentre where people are contagious.
Technical/IT	No Subtopics	Non-healthcare technical issues. Examples: trouble with texting or health IT, video conferencing and virtual care access
Maternal & Child Health	No Subtopics	Any mention or pertaining to pregnancy, breastfeeding, motherhood, and early childhood care
Health Education	No Subtopics	Providing information to help patients beyond simple advice, with the intent to increase knowledge - can be verbal, written or in the form of visual aids like pamphlets, courses. Examples: pamphlet on what diabetes is, teaching how to self- monitor blood pressure, etc.
Stigma	No Subtopics	A mention of the disapproval of, or <u>discrimination</u> against, an individual or group based on perceivable characteristics that serve to distinguish them from other members of a society. Social stigmas are commonly related to <u>culture</u> , <u>gender</u> , <u>race</u> , <u>socioeconomic</u> <u>class</u> , age, sexual orientation, <u>body image</u> , intelligence or lack

		thereof, and health. Can be self-directed.

570

NP = Not Predictable (best model did not meet F1 performance cutoff and was not applied)

571 NT = Not Tested (insufficient data to develop models)

572

573

574 **S4 Table.** Comparison of the odds of discussion of predictable conversation topics of interest

575 (i.e., those conversation topics of interest for which we developed a classification model of

576 interest meeting the F1≥0.7 performance cutoff) by patient demographic and clinical factors in

- 577 the complete conversation corpus (n=12,119). Presented p-values were adjusted for multiple
- 578 testing using the Benjamini-Hochberg correction.

TOPIC COMPARISON ODDS RATIO (95% CI, adj. p-va	p-value)
--	----------

	(vs. reference)	
	Female vs. Male	1.04 (0.96-1.13, p=0.39)
Symptoms	Age (per year increase)	1.00 (1.00-1.00, p=0.47)
	Contact vs. Case	1.25 (1.06-1.47, p=0.02)
	Female vs. Male	0.87 (0.80-0.94, p=0.0012)
