36 Abstract

37 Background and Aims

The ongoing antimicrobial resistant crisis heralds the need for new therapeutics against enteric
 infection. In mouse models, colon epithelial peroxisome proliferator-activated receptor-γ (PPAR γ) signaling limits oxygen and nitrate luminal bioavailability, thereby preventing bacterial pathogen

41 colonization. However, whether this mechanism operates similarly in humans remains uncertain.

42 Methods

To investigate, we used the cloud-based TriNetX Analytics Platform which aggregates health records from 117 million patients across 66 US healthcare organizations, to assess the risk of bacterial enteric infection among diabetic patients prescribed thiazolidinediones, a class of PPARy agonists, to other anti-diabetes medications.

47 Results

Among 85,117 thiazolidinedione users, we observed a 22-49% lower risk of bacterial enteric infections compared to users of other anti-diabetes medications. This reduction in risk was consistent across high-risk individuals, regardless of sex or age. Similar results were replicated in high-risk patients when thiazolidinedione users were directly compared to those on DPP-4 inhibitors.

53 Conclusion

These findings support the potential protective role of PPAR-γ signaling against bacterial enteric
 infection and call for further clinical investigation.

60 Introduction

61 The body's primary defense against bacterial enteric infection relies heavily on the abundant and 62 diverse intestinal microbiota [1,2]. These gut commensal microbes confer protection by direct 63 bacteria-to-bacteria interactions and activating host immune defenses—a phenomenon known as 64 colonization resistance [1,2]. Amid the ongoing antimicrobial resistant crisis, understanding the 65 mechanisms of colonization resistance has gained increasing importance. Identifying microbial 66 metabolites, proteins, or host receptors involved in preventing infection can lead to new anti-67 infective strategies and potentially reduce the 1.6-2.1 million annual diarrheal deaths worldwide 68 [3].

69 Recent mechanistic studies have highlighted a central role of the host nuclear hormone receptor 70 peroxisome proliferator-activated receptor (PPAR-y) in colonization resistance [4,5]. Commensal 71 colonic microbes, predominantly obligate anaerobes, thrive in an oxygen- and nitrate- deprived 72 environment, limiting the expansion of facultative anaerobic organisms such as Salmonella and 73 Enterobacteriaceae. These microbes maintain the low-oxygen environment by producing metabolites such as butyrate, which activates PPAR-y in colonocytes [4,5]. This activation 74 75 enhances oxygen consumption by the host, sustaining the protective anaerobic state. In mouse 76 models, depletion of PPAR-y signaling-triggered by antibiotics or a high-fat diet-has been 77 associated with increased bacterial pathogenesis, aligning with well-known patient risk factors [4-78 9]. Pharmacological PPAR-y agonists have also shown promising results in restoring this 79 protective effect [10]. However, it remains unclear whether PPAR-y offers similar protection 80 against enteric infection in humans.

Thiazolidinediones, a class of PPAR-γ agonists, are commonly used in the management of type 2 diabetes mellitus (T2DM) [11,12]. Assessing the risk of bacterial enteric infection in thiazolidinediones users compared to those receiving other anti-diabetes medications could provide insights into the viability of targeting PPAR-γ for anti-infective purposes. In this study, we

It is made available under a CC-BY-NC-ND 4.0 International license .

- 85 conducted a population-based analysis in the US to assess the risk of bacterial enteric infection
- 86 in T2DM patients using thiazolidinediones anti-diabetes medications.

87

- 88 Methods
- 89 Data

We used the cloud-based TriNetX Analytics Platform, US Collaborative Network, to obtain webbased real-time secure access to fully deidentified electronic health records of 117 million patients from 66 health care organizations, representing 27% of the US population from all 50 states. Both inpatient and outpatient settings mostly from large academic medical institutions in the US, as well as persons from diverse geographic, age, race and ethnicity, income, and insurance groups are represented. The geographic distribution of patients from the TriNetX platform is 25% in the Northeast, 17% in the Midwest, 41% in the South, and 12% in the West, with 5% unknown.

97

98 Ethics Statement

99 The TriNetX platform aggregates and HIPAA de-identifies data contributed from the electronic 100 health records of participating healthcare organizations. The TriNetX platform also only reports 101 population-level results (no access to individual patient data) and uses statistical blurring, 102 reporting all population-level counts between 1 and 10 as 10. Because this study used only 103 deidentified patient records, it was exempted from review by the MetroHealth System Institutional 104 Review Board.

105

106 Study populations

107 Risk for bacterial enteric infection can often be based on factors that are not well captured by
108 electronic medical records, including consumption of undercooked meat or international travel,
109 and may be a rare occurrence in those without risk factors present. Therefore, the outcome of

It is made available under a CC-BY-NC-ND 4.0 International license .

bacterial enteric infection after prescription of thiazolidinedione or other anti-diabetes medication was determined among a "low-risk" and "high-risk" cohort. Low-risk for bacterial enteric infection was defined as no prior history of bacterial enteric infection. High-risk was defined as persons with a previous diagnosis of bacterial enteric infection, suggesting risk factors for disease such as altered gut microbiota, behavioral and environmental factors, or predisposing chronic diseases are present [13-16].

116

The study was designed for a 5-year recruitment date, from 3 January 2017 to an end date of 3 January 2022. The start date was chosen to help include the approval of semaglutide for T2DM management (FDA approved Dec 2017) and the end date was chosen to minimize overlap of GLP1 agonist approval for weight loss in those without diabetes (FDA approved June 2021). The index events for each were time of anti-diabetes medication prescription

122

123 The study population at low-risk for bacterial enteric infection

Two thiazolidinediones are available in the United States, pioglitazone and rosiglitazone. 124 125 Accordingly, all persons >18 years of age between January 2017 and January 2022 who within 1 126 month after a medical encounter for the diagnosis of type 2 diabetes mellitus were prescribed 127 thiazolidinediones (pioglitazone or rosiglitazone) or non-thiazolidinediones anti-diabetes 128 medications (Glucagon-like peptide-1 (GLP-1) analogues, insulin, metformin, sulfonylureas, alpha glucosidase inhibitors, DPP-4 inhibitors, SGLT2 inhibitors), and had no prior history of bacterial 129 130 enteric infection before index event (prescription of anti-diabetes medication) were included. The 131 study population was then divided into two cohorts: (1) thiazolidinedione-users at low risk and (2) 132 non-thiazolidinedione users at low risk. Troglitazone users were excluded from the study as the 133 medication is not available in the US due to its hepatoxicity. In the non-thiazolidinedione cohort, 134 persons with thiazolidinedione prescription were excluded from the non-thiazolidinedione cohort.

It is made available under a CC-BY-NC-ND 4.0 International license .

136 The study population at high-risk for bacterial enteric infection

137 Two thiazolidinediones are available in the United States, pioglitazone and rosiglitazone. 138 Accordingly, all persons >18 years of age between January 2017 and January 2022 who within 1 139 month after a medical encounter for the diagnosis of type 2 diabetes mellitus were prescribed 140 thiazolidinediones (pioglitazone or rosiglitazone) or non-thiazolidinediones anti-diabetes 141 medications, and had prior history of bacterial enteric infection before index event (prescription of 142 anti-diabetes medication) were included. The study population was then divided into two cohorts: 143 (1) thiazolidinedione-users at high risk and (2) non-thiazolidinedione users at high risk. 144 Troglitazone users were excluded from the study as the medication is not available in the US due 145 to its hepatoxicity. In the non-thiazolidinedione cohort, persons with thiazolidinedione prescription 146 were excluded from the non-thiazolidinedione cohort.

147

148 Statistical analysis

149 For each study cohort, the thiazolidinedione users and non-thiazolidinedione users were 150 propensity score matched (1:1 using nearest neighbor greedy matching with a caliper of 0.25 151 times the standard deviation) on covariates that are potential risk factors for bacterial enteric 152 infection including diabetes severity, such as age, sex, race, ethnicity, overweight and obesity, 153 lifestyle problems, ischemic heart disease, liver disease, kidney disease, lung disease, 154 hypertension, hyperlipidemia, cerebrovascular disease, atherosclerosis, other peripheral vascular 155 disease, tobacco use, alcohol use, human immunodeficiency virus (HIV), organ transplant, use 156 of immunosuppressants, use of chemotherapeutics, and Hemoglobin A1C levels.

157

The outcome bacterial enteric infection that occurred in the 6-month time window after the index event (prescription of medication) were compared between the matched medication groups. The status of bacterial enteric infection was defined by ICD-10 A00-A05 (A00: Cholera, A01: Typhoid and paratyphoid fevers, A02: Other salmonella infections, A03: Shigellosis, A04: Other bacterial

It is made available under a CC-BY-NC-ND 4.0 International license .

intestinal infections, A05: Other bacterial foodborne intoxications, not elsewhere classified). As
counts of bacterial enteric infection were low in the cohort, risk for an individual bacterial species
(i.e. *Salmonella sp, Enterohemorrhagic E coli*) precluded statistical analysis (most counts were
less than 10, therefore were rounded to 10 by TriNetX) and was not performed. Only a composite
outcome was investigated.

167

168 Several subgroup analyses were performed to assess the robustness of our results and possible 169 bias. First, outcomes were examined when stratified by sex and age. Second, given diabetes 170 medications are often prescribed in combination, it was necessary to evaluate whether other medications commonly administered alongside thiazolidinediones could confound observed 171 172 effects. However, thiazolidinediones are rarely used for the management of T2DM because of 173 weight gain, pedal edema, and heart failure exacerbation, leading to their classification as a third 174 line option. Accordingly, thiazolidinediones were compared with another third-line anti-diabetes 175 medication, dipeptidyl peptidase-4 inhibit0rs (DPP-4) inhibitors. Age and sex stratified analysis 176 were not performed between thiazolidinediones and DPP-4 inhibitors as subgroups often had less 177 than 10 persons with the desired outcome. TriNetX to maintain deidentification does not provide 178 actual counts when below 10, which precludes accurate statistical analysis. All statistical analysis 179 were performed with the TriNetX Advanced Analytics Platform. The TriNetX platform calculates 180 RRs and associated confidence interval (CI) using R's Survival package, version 3.2-3, with 181 proportional hazard assumption tested using the generalized Schoenfeld approach. Statistical 182 significance was set a 2-sided P value of <0.05.

183

184 **Results**:

185

Association of thiazolidinedione with risk of bacterial enteric infection in patients at low
 risk
 188

The study population consisted of 85,917 and 2,154,426 persons with T2DM who between
1/2017-1/2022 were prescribed thiazolidinedione or non-thiazolidinedione anti-diabetes

It is made available under a CC-BY-NC-ND 4.0 International license .

191 medications, respectively, and had no prior history of bacterial enteric infection. Persons on 192 thiazolidinediones compared to non-thiazolidinedione were more likely to be older, male, white, 193 and had higher prevalence of overweight and obesity, chronic kidney disease, and Hgb A1C levels 194 greater than 9 (**Table 1**).

195

196 After 1:1 propensity matching, demographic and clinical characteristics were balanced (85,916 in 197 each cohort, 63.2 years of age, 42.9% Female, 12.8% Black, 67.7% White, 14.3% Hispanic) 198 (Table 1). Matched cohorts were followed for 6 months after the index event. Compared to anti-199 diabetes non-thiazolidinedione medications, thiazolidinedione was associated with a lower risk of 200 incident bacterial enteric infection among those at low-risk (0.03% vs 0.06%; RR 0.51, 95% CI 201 0.32, 0.82). An association of lower risk for bacterial enteric infection was observed across age 202 and sex, however only among those >65 years were findings statistically significant (0.02% vs 203 0.05%; RR 0.44, 95% CI 0.23,0.88) (Figure 1).

204

Association of thiazolidinedione with risk of bacterial enteric infection in patients at high risk

The study population consisted of 1,975 and 57,963 persons with T2DM who between 1/2017-1/2022 were prescribed thiazolidinedione or non-thiazolidinedione anti-diabetes medications, respectively, and had prior history of bacterial enteric infection. Persons on thiazolidinediones were more likely to be Hispanic and White, and had higher prevalence of overweight and obesity, hypertension, hyperlipidemia, and Hb1C levels greater than 9.

213

After 1:1 propensity matching, demographic and clinical characteristics were balanced (1,974 in each cohort, 63.0 years of age, 44.1% Female, 16.9% Black, 65.4% White, 20.8% Hispanic) (**Table 1**). Matched cohorts were followed for 6 months after the index event. Compared to antidiabetes non-thiazolidinedione medications, thiazolidinedione was associated with a lower risk of incident bacterial enteric infection among those at high risk (17.6% vs 22.5%; RR 0.78, 95% CI

It is made available under a CC-BY-NC-ND 4.0 International license .

0.69,0.88). An association of lower risk for bacterial enteric infection was observed across all sex
and age subgroups (Figure 2).

221

Association of thiazolidinedione compared to DPP-4 inhibitors with risk of bacterial enteric infection in patients at low and high risk (sensitivity analysis)

In the matched cohorts, thiazolidinedione use compared to those on DPP-4 inhibitors in patients

226 with T2DM was associated with a lower risk of bacterial enteric infection in those at high-risk (RR

- 227 0.82, 95% CI 0.72,0.93) and not those at low-risk (RR 0.96, 95% CI 0.56, 1.65) (**Figure 3**).
- 228
- 229

230 Discussion

231 Our analysis identified a significant association between thiazolidinedione use and a reduced risk 232 of bacterial enteric infections in T2DM patients, consistent with findings from animal models. This 233 protective effect was observed in both low- and high-risk populations, with notable reductions in 234 infection across various age and sex subgroups, particularly in high-risk individuals with a history 235 of prior infections. The reduced risk seen when comparing thiazolidinediones to third-line diabetes 236 medications (DPP-4 inhibitors) further supports the hypothesis that modulating PPAR-y signaling 237 mitigate bacterial enteric infections, especially in high-risk situations-for example, protracted 238 antibiotic use during hospitalization, international travel to high incidence locales, or outbreaks in 239 nursing homes and chronic care facilities.

240

Thiazolidinediones are typically used as a third-line medications when other anti-diabetes medications have proven ineffective or when insurance limitations restrict alternative options [12]. Consequently, thiazolidinedione users often represent a population with more severe or poorly controlled diabetes, characterized by frequent healthcare encounters and lower socioeconomic status [17-18]. These factors are associated with an increased risk of bacterial enteric infection,

It is made available under a CC-BY-NC-ND 4.0 International license .

suggesting the protective effect of thiazolidinediones may be greater than what this analysisindicates [19-21].

248

249 Repurposing thiazolidinediones is not a novel concept. Initially, PPAR-y was believed to primarily 250 function on adipose tissue, regulating insulin resistance, which led to the development of 251 thiazolidinediones for diabetes management [22]. However, investigators soon appreciated the 252 abundance of PPAR-y in colonic epithelial cells and its involvement in colon cancer [23,24]. 253 Subsequently, PPAR-y signaling was shown to reduce colonic inflammation, prompting the 254 exploration of thiazolidinediones for inflammatory bowel disease [25]. Promising results were 255 observed in mouse models and clinical trials [25-27]. Despite these benefits, concerns over 256 toxicities, such as weight gain, fluid retention, and heart failure, have overshadowed the benefits 257 of thiazolidinediones. Therefore, while this study suggests thiazolidinediones may protect against 258 bacterial enteric infection, their repurposing for this indication is likely limited by their associated 259 risks.

260

Fortunately, there are alternative ways to increase PPAR-γ signaling. For instance, mesalamine (5-ASA), a PPAR-γ agonist widely used for treating mild to moderate ulcerative colitis, may offer a safer alternative. Studies suggest that 5-ASA prevents the expansion of colitogenic bacteria such as *Escherichia coli* [10], indicating its potential role in preventing bacterial enteric infection in high-risk individuals.

266

Dietary modifications may also enhance PPAR-y signaling. A high-fiber diet can increase butyrate levels, which, in turn, activate PPAR-y. However, this depends on the presence of a gut microbiota capable of butyrate production. Unsaturated fatty acids, found in dairy and meat products, are natural PPAR-y ligands and may also promote colonic health, although achieving sufficient

It is made available under a CC-BY-NC-ND 4.0 International license .

intraluminal concentrations *in vivo* remains controversial. Small animal studies have
 demonstrated possible benefits from such dietary interventions [28,29].

273

274 One hypothesis behind the protective effects of PPAR-y activation is its ability to maintain an 275 anaerobic environment in the gut, which helps prevent bacterial enteric infections. However, this 276 mechanism does not directly explain why thiazolidinediones may also protect against 277 Clostridioides difficile, an obligate anaerobe. It is possible that PPAR-y signaling supports the 278 growth of beneficial anaerobes such as *Clostridium scindens* or *Blautia producta*, which inhibit C. 279 difficile through the production of secondary bile acids and lantibiotics, respectively [30,31]. 280 Further, PPAR-y activity in macrophages, which has been shown to ameliorate colonic 281 inflammation, may also contribute to this protective effect. Given that thiazolidinediones are 282 primarily absorbed in the small intestine and may not directly reach the colon, this macrophage-283 mediated mechanism merits further investigation [10].

284

285 Limitations

286 There are limitations that bear consideration when interpreting the results of this study. Residual 287 confounding, particularly diabetes severity, may impact the findings. Although we controlled for 288 factors like ischemic heart disease, peripheral vascular disease, chronic kidney disease, and 289 HbA1C levels, fully characterizing the severity of diabetes remains a challenge. Further, 290 medication adherence cannot be confirmed based on electronic health records. However, our 291 inclusion of individuals with thiazolidinedione or other anti-diabetes prescriptions following a 292 healthcare encounter for T2DM suggests active management of the disease. Limited sample 293 sizes precluded an analysis of dose-dependent effects and we could not assess the duration of 294 thiazolidinedione use required for a protective effect. Further, since T2DM is often managed with 295 a combination of medications, it is possible that other medications commonly used alongside 296 thiazolidinediones contributed to the observed protective effect. To address this, we conducted a

It is made available under a CC-BY-NC-ND 4.0 International license .

297 direct comparison with DPP-4 inhibitors, which showed a decreased risk of bacterial enteric

infection in high-risk individuals. Lastly, the severity of enteric infections was not captured in this

study, so it remains unknown whether thiazolidinediones can reduce disease severity.

300

301 Conclusion

Bacterial enteric infections remain a significant public health concern, with acute gastroenteritis causing an estimated 179 million outpatient visits and nearly 500,000 hospitalizations annually [32-33]. Current antimicrobial treatments are often inadequate, as antibiotics can prolong symptoms, increase bacterial shedding, and lead to recurrence [14-16]. Given the limitations of existing treatments, preserving beneficial intestinal microbes with alternative therapies that minimize collateral damage to the microbiome is a key consideration. In this context PPAR-γ agonists may offer a promising alternative.
