#### 48 Abstract

- 49
- 50 Objectives
- 51 Systematic review of studies evaluating evidence-based health information (EBHI)
- 52 and decision aids (DAs) in terms of the extent to which inequity-producing factors
- 53 have been considered and how these factors affect access to health-related
- 54 information and informed decision-making.
- 55
- 56 Study design
- 57 Systematic review of randomised controlled trials.
- 58
- 59 Methods
- 60 Systematic searches were performed in the Cochrane Library, PubMed, Embase,
- 61 PsycINFO, CINAHL, ERIC and PSYNDEX from inception to May 2023 to identify
- 62 evaluation studies of EBHI and DAs that take into account factors associated with
- 63 unequal opportunities as defined by PROGRESS Plus. Information on the effect of
- 64 these factors was extracted and analysed in terms of outcomes relevant to the
- 65 decision-making process.
- 66
- 67 Results
- 68 Few studies have examined the impact of EBHI/DAs on outcomes relevant to
- 69 decision-making with respect to inequity-producing factors. In our final synthesis,12
- 50 studies were included. A positive association between the effectiveness of the
- 71 intervention and the disadvantage status could be found twice and a negative
- 72 association in three studies. Overall, most of the studies found no difference in
- 73 knowledge gain, decision conflict and shared decision-making (SDM) between those
- advantaged and disadvantaged in terms of ethnicity, gender, education, age,
- income, health literacy, numeracy or socioeconomic status (SES). However, few
- trials examined this effect and the effect was considered solely in subgroup analyses
- that were probably underpowered, so asymmetries between these groups may not
- 78 have been detected in the existing designs.
- 79
- 80 Conclusion
- 81 EBHI and DAs have been shown to be effective in promoting decision-making and
- thus in improving health care. To improve health care equitably, greater attention
- 83 needs to be paid to methodological requirements in evaluations to fully capture
- 84 potential differences in access to health-related information between individuals or in
- 85 populations within the target groups of EBHI/DAs.
- 86
- 87 PROSPERO registration: CRD42018103456
- 88 80
- 89 Key words: Equity, decision aids, decision-making, informed choice, evidence-based
- 90

#### 91 What is already known?

- There is evidence that EBHI and DAs do not reach certain patient groups
   because while being developed and evaluated they do not adequately take into
   account differences in access to health-related information between different
   social groups.
- There is insufficient evidence whether EBHI and DAs are equally effective for
   people with factors that are more or less associated with equal access to health
   information.
- 99

#### 100 What the study adds

- A systematic review of evaluation studies of EBHI and DAs to consider factors that lead to inequity and analysis of how these factors influence the intervention effects in terms of access to health-related information and outcomes relevant for decision-making.
- 105

#### 106 How this study might affect research, practice or policy?

- Our research makes a valuable contribution to more equitable health care by
   stressing critical inequality factors that may influence informed decision-making
   with the help of EBHI and DAs.
- 110
- 111

#### 112 Introduction

113

114 Evidence-based health information (EBHI) and decision aids (DAs) have the 115 potential to reduce inequity by providing equal access to relevant information. They 116 aim to facilitate informed decision-making by providing all those facing a health 117 decision with sufficient knowledge, with which people can make a decision in line with their treatment preferences [1]. Unlike EBHI, DAs directly aim to elicit 118 preferences and support patient decision-making by providing decision-makers with 119 detailed and personalised options and outcomes <sup>[2]</sup>. EBHI and DAs are developed in 120 an extensive process that involves continuous adaptation<sup>[3]</sup>. Information needs and 121 requirements of the target group are crucial throughout the development process <sup>[4]</sup>. 122 123 However, the group targeted by the general decision-making situation can be very 124 heterogeneous in terms of their individual ability to understand and process 125 information and to draw conclusions. Accordingly, there is a risk that those 126 individuals or groups within the target group who are already disadvantaged in terms 127 of informed and shared decision-making (SDM) will benefit least from EBHI and DAs. 128 It has long been recognised that patient education materials fail to adequately 129 address differences in access to health-related information between different social groups by not taking sufficient account of factors that are associated with inequalities <sup>[5-7]</sup>. These factors include race/ethnicity, language, gender, education, 130 131 132 socioeconomic status (SES) and age, which, according to PROGRESS-Plus, lead to unequal opportunities and thus differences in health outcomes <sup>[8]</sup>. Many of the factors 133 134 influence access to health care in general. For instance, written information is often 135 at a higher reading level or developed for general audiences and therefore does not 136 reach people with low literacy skills, education, and SES or those from diverse cultural groups <sup>[7, 9, 10]</sup>, although the checklist of quality criteria from the International 137 138 Patient Decision Aid Standards (IPDAS) has always included the use of plain language [11]. 139

It is made available under a CC-BY-NC-ND 4.0 International license .

140 At present, it is unclear whether EBHI and DAs are equally effective for all patient 141 groups or which subgroups benefit (most), as few trials and systematic reviews have 142 investigated this effect. However, evidence exists that disadvantaged patients (e.g. 143 with lower literacy skills, education and socioeconomic status) are less likely to make 144 informed choices and are more likely to regret their decision than advantaged groups 145 <sup>[7]</sup>. Furthermore, a patient-level meta-analysis based on seven unpublished RCTs 146 from the Knowledge and Evaluation Research Unit of the Mayo Clinic, USA. 147 suggests that DAs during the clinical encounter lead to a greater increase in risk knowledge in patients with higher education than in those with lower education <sup>[12]</sup>. 148 149 Subgroup effects on the basis of race were imprecise. The most current Cochrane Review published in January 2024<sup>[2]</sup>, did not investigate whether the positive effect 150 151 of DAs applies equally to all patient subgroups. This gap is the subject of our review. 152 However, the authors of the review noted that more robust evidence that decision 153 aids can improve health equity or reduce inequalities in access to care could further support their use in clinical practice, which is currently rare <sup>[2]</sup>. 154 155 156 Our review aims to systematically assess to which extent studies evaluating the 157 effectiveness of EBHI/DAs have considered factors that lead to inequalities in access 158 to health-related information. We also analyse how their effectiveness in terms of 159 decision outcomes varies within the target groups according to these factors. 160 161 162 **Methods** 163 The reporting follows the Preferred Reporting Items for Systematic Reviews and 164 Meta-Analysis (PRISMA) 2020<sup>[13]</sup> and PRISMA-Equity statement<sup>[14]</sup> to account for 165 equity-related aspects. PROSPERO has been used for prospective registration 166 167 (CRD42018103456). 168 169 Study inclusion and exclusion 170 171 Studies were included: (1) if they compared the effectiveness of EBHI/DAs 172 (intervention) with usual care or no information (control) between different social 173 groups in a RCT, (2) when a specific health decision needed to be made, and (3) if 174 the main outcome of interest was an informed decision or a related aspect. 175 Therefore, we also included studies that analysed effects on knowledge, attitude, 176 uptake and related outcomes such as decision concordance, risk perception, recall, 177 understanding, intention, SDM, decision conflict and regret. Furthermore, studies (4) 178 had to include an analysis of the effects based on at least one characteristic that 179 stratifies health opportunities and outcomes according to the PROGRESS-Plus 180 definition (place of residence, race/ethnicity/culture, occupation, sex, religion, 181 education, SES, social capital, age, disability and sexual orientation) in their results

section. We also included non-EBHI/DA-interventions, as we expected few studies to
 examine the effectiveness of EBHI/DAs in different social groups. These studies had

examine the effectiveness of EBHI/DAs in different social groups. These studies had
 to provide information about the benefits and harms of the treatment options (e.g.

184 to provide information about the benefits and narms of the treatment options (e.g. 185 participation vs. non-participation) for those about to make a decision – one of the

186 minimum requirements for EBHI <sup>[15]</sup>.

187 We excluded: (1) studies comparing different formats of EBHI/DAs with the same

188 content (e.g. tabular vs. written information), (2) studies focusing on a concrete

disadvantaged group (e.g. people with low literacy), and (3) studies including a

multicomponent intervention, where the intervention effect is not clearly attributableto the (non-)EBHI/DA.

192

#### 193 Search strategy, study selection and data extraction

194

We searched the Cochrane Library, MEDLINE and PubMed (via PubMed), EMBASE
(via Ovid), PsycINFO (via Ovid), Cumulative Index to Nursing and Allied Health
Literature (CINAHL) (via Ovid), ERIC and PSYNDEX (via Ovid) from inception to
May 2023 using a combination of English-language search terms including or
describing determinants and factors of health inequality in combination with the
intervention and outcome (*Supplement 1*). EndNote 20 was used for reference
management.

202

After duplicates were removed, two reviewers independently reviewed all titles and abstracts via the browser application Rayyan <sup>[16]</sup>. The first reviewer was always the first review author (CE); the second reviewer varied (CH, JB, JH). Studies included were then screened in full text by two reviewers independently, with disagreements resolved by discussion. Additionally, reference lists of included studies and of relevant systematic reviews identified were checked for grey literature.

A standard data extraction form was used to extract data, focusing on which aspects of inequality, as defined by PROGRESS Plus, were taken into account and the

- 211 impact of each aspect for the respective factor.
- 212

#### 213 Risk of Bias

214

Two people independently assessed the risk of bias using Cochrane's ROB 2.0<sup>[17]</sup> tool for RCTs. The first person was always the first review author (CE); the second person varied (CM, DA, JB, PB). Disagreements were resolved by discussion and, if necessary, with the involvement of a third person (FGR).

219

#### 220 Data synthesis

221

Due to the lack of relevant reported data and heterogeneous instruments to access 222 223 outcomes (e.g. informed choice) and disadvantage level of study participants (e.g. 224 health literacy (HL)) and to the effect of outcomes being available for only some subgroups in the identified studies, the Grading of Recommendations Assessment, 225 Development and Evaluation (GRADE) system<sup>[18]</sup> could not be applied and a meta-226 analysis was not possible. The results were therefore summarised narratively and 227 effects visualised using harvest plots <sup>[19]</sup>, including only studies with low and medium 228 229 risk of bias.

230

### 231 Patient and public involvement

232

We did not involve patients in the design of the trial or in the dissemination of the
results.

#### 236 Results

237

238 The literature searches identified 3803 studies, of which 216 potentially relevant

239 studies were included for full-text screening. Data extraction was performed for

It is made available under a CC-BY-NC-ND 4.0 International license .

seven studies. Five additional studies were identified from the reference lists of the studies included and of relevant systematic reviews. The study selection process is shown in *Figure 1*. Sixty studies that were initially considered eligible were excluded due to wrong intervention (e.g. multicomponent analysis without separate analysis of the EBHI/DAs), 118 studies lacked an equity analysis, eight studies used the wrong study design and ten studies reported on the wrong outcome or population. See the appendix for a list of excluded studies and specific reasons (*Supplement 1*).

247 248

# 249 Characteristics of included studies

250 Of the 12 trials finally included, nine studies <sup>[6, 7, 20-26]</sup> used an intervention developed 251 according to the IPDAS criteria<sup>[4]</sup>, so were EBHI/DAs; the remaining three<sup>[27-29]</sup> were 252 non-EBHI/DAs. Nine studies were carried out in the USA and one study each in the 253 254 UK, Australia and Canada in heterogenous clinical settings (e.g. specialised medical centres and clinical sites, primary care settings/practices). Two studies showed a 255 thematic overlap in the decision-making situation (prenatal testing)<sup>[20, 29]</sup>; all other 256 topics occurred only once. Due to the heterogeneous decision-making situations, the 257 258 target groups of the intervention were also very diverse and ranged from pregnant 259 women to elderly patients with increased risk or pre-existing conditions (e.g. kidney 260 disease, early stage breast cancer), among others. Trial sizes ranged from 60 to 900 261 participants, meaning that individual subgroups by inequity producing factor were 262 sometimes very small. Further key characteristics of the included publications and 263 trials can be found in *Table 1*.

Author/ Year	Study design	Country	Setting	Population	Inequity-factor (by PROGRESS Plus)	N	Intervention	Control	Intervention effect assessment	Outcomes of relevance	Risk of Bias
Durand et al. 2021 <sup>[7]</sup>	RCT	USA	7 clinics within 4 National Cancer Institute- designated cancer centers	Women with biopsy- confirmed diagnosis of early staged breast cancer (stages I-IIIA)	By socioeconomic status (SES), education	616	Evidence- based (pictural) Option Grid on breast- conserving surgery and mastectomy	Usual care (surgeons provided their standard information about breast cancer)	Subgroup analysis	Knowledge, decision concordance, SDM, decision regret, treatment choice	Some concerns
Gordon et al. 2017 <sup>[27]</sup>	RCT	USA	2 medical centres	Kidney transplant candidates	By age, race/ethnicity, gender, education, income, employment status, HL	288	Non-evidence based iPad app, "Inform Me: about Increased Risk Donor Kidneys" (n=133)	Control group: routine transplant education and 31-item multiple- choice posttest on paper after (n=155)	Subgroup analysis	Knowledge	Some concerns
Healton et al. 1999 <sup>[28]</sup>	RCT	USA	Community family planning clinics and hospital-based HIV centres in 19 sites from nine cities	Women including Black, Puerto Rican & Non Puerto Rican Latinas	By age, education, race/ethnicity, language preference	653	Non-evidence- based patient brochure on zidovudine therapy during pregnancy to reduce perinatal HIV transmission	No brochure	Subgroup analysis	Knowledge, intention, attitude	High
Hewison et al. 2001 <sup>[29]</sup>	RCT	UK	One medical centre and outpatient	Consecutive women referred for antenatal care to the Hull Maternity Hospital	By age	2000	Non-evidence based video information at home for Down syndrome screening (n=993)	Control: women who did not receive the screening video at home (n=1007)	Subgroup analysis	Knowledge	Some concerns
Hunter et al. 2005 <sup>[20]</sup>	RCT	Canada	One children's hospital	Pregnant women aged 35 higher at the time of delivery and their partners; gestational age of 18 weeks or less	By gender	352	Non-evidence based audiotape- booklet decision aid + option of genetic counselling (n=116)	Control arms: 1. individual genetic counselling (n=126) 2. genetic counselling in a group (n=110)	Subgroup analysis	Knowledge, decisional conflict	Some concerns
Patzer et al. 2018 <sup>[21]</sup>	RCT	USA	Three transplant centres	Patients living with end- stage renal disease (ESRD); 18 to 70 years of age, no previous solid	By ethnicity, gender, HL, numeracy	443	Evidence- based web- based DA about kidney	Centre-specific standard of care; education about kidney	Subgroups analysis	Knowledge	High

### 265 **Risk of bias of included studies**

#### 266

Risk of bias was assessed for the individual trials at the study level. Only two out of the 12 trials were judged to be at low risk of bias across all domains and three of the trials as having a high risk of bias in at least one area (*Figure 2*). Five studies each were classified as having some concerns with regard to the randomisation process or the selective reporting of study results. For instance, although most trials were registered, information on a priori planned analyses and other details were often missing.

274 Crucially, none of the 12 trials was initially designed to assess the effect of the

275 intervention on different social groups; most of the trials assessed the effect through

subgroup analyses by social group. This often led to very small numbers of

- participants for the subgroups, suggesting that the trials were insufficiently powered
   to detect an intervention effect. Therefore, the overall quality of the evidence is rated
   as moderate.
- 280
- 281

# 282 Outcomes relevant for assessing the intervention effect

Most frequent outcomes were knowledge in 11 out of the 12 studies and decisional
conflict in six studies (*Supplement 2 - table S1*). Intention/uptake, SDM and
informed decision/decision concordance were outcomes of interest in three studies
each, decision regret and attitude were outcomes in one study each.

288 289

# 290 **Consideration of inequity-creating factors**

291

Five inequity-producing factors (as according to PROGRESS-Plus) were considered at least once (

*Table 2*). Six out of 12 studies considered more than one factor but only two <sup>[7, 30]</sup>
considered intersectionality, which refers to the overlapping of various disadvantages
(e.g. low-level education and cultural background) <sup>[31]</sup>. In one of the studies, the
authors defined study participants as socioeconomically disadvantaged if they were
non-white, had low HL or numeracy skills and had a low income (< USD 40,000) <sup>[30]</sup>.
In the second study <sup>[7]</sup>, patients with lower SES were defined as having at least two
of the following characteristics: lower income, lower education or underinsurance.

301 Only one further study <sup>[28]</sup> mentioned that one of the subgroups (non-Puerto Rican 302 Latinas) might benefit the least, as they had the lowest level of English skills and

- 303 some did not even speak Spanish.
- 304
- 305

# Table 2: Sociodemographic factors used in the included studies (N = 12) to assess the intervention effect in subgroups.

308 X<sup>a</sup>: SES assessed by education, income and occupational status.

309 X<sup>b</sup>: SES assessed by race, HL/numeracy and income.

310

311

The intervention effect was most frequently observed according to ethnicity/language preference (

314 **Table 2**). The most commonly assessed outcomes by inequality factors were

knowledge, decisional conflict and SDM (*Supplement 2 - Table S2*). The results for

316 the inequality factors are only summarised below for these three factors, as the

number of studies for other factors is very small, making it almost impossible to drawconclusions.

319

320

321 322

#### 1 Synthesis of intervention effect by inequality factors

323 Overall, among heterogeneous studies in terms of decision-relevant outcomes and 324 inequality factors only three studies mentioned group-specific intervention

325 effectiveness <sup>[6, 7, 22]</sup>. The results are summarised narratively for each inequality

- factor. Only studies with low and medium risk of bias are presented in the forest plots for the most frequent endpoints (*Figure 3 A-C*).
- 328

329 Age

330

Three trials <sup>[6, 28, 29]</sup> tested for a group-specific intervention effect that was indicated in one high-risk-of-bias study alone (only one knowledge aspect) <sup>[28]</sup>. Another trial

333 reported higher knowledge scores after intervention across four different age groups

334 without indication of differential effectiveness <sup>[27]</sup>. Age groups do not seem to be

disadvantaged by interventions, whether EBHI/DA or not (*Figure 3 A-C*), but the lack

- 336 of pre-post assessments across intervention groups and heterogeneous
- 337 categorisations of age groups may have concealed such differences.
- 338
- 339 *Education*340

None of the four trials that analysed knowledge effects confirmed an association with 341 education <sup>[6, 25, 28, 30]</sup> (Supplement 2 – table S4). A fifth revealed similar knowledge 342 gains <sup>[27]</sup> (Figure 3 A-C). Any EBHI/DA seemed to be equally effective for people 343 with higher and lower levels of education for SDM <sup>[6, 30]</sup>, decisional conflict <sup>[22, 30]</sup>, 344 attitudes <sup>[28]</sup>, intention <sup>[28]</sup> and informed choice <sup>[22]</sup>, although each of these endpoints 345 346 was assessed in a maximum of two studies. A single study <sup>[7]</sup> found that the 347 intervention increased disparities in decision regret between those with and without 348 high school diploma.

349

351

- 350 Ethnicity/race and language preference
- Among trials where ethnicity was taken into account (Supplement table S5), one <sup>[6]</sup> 352 353 indicated that the intervention was more effective for white patients than for other 354 ethnic groups (e.g. African Americans, Latinas or other racial/ethnic groups) in terms 355 of knowledge (Figure 3 A). The study, however, lacked an adjustment for multiple testing. Three high-risk-of-bias trials had contradictory results regarding differential effectiveness <sup>[21, 26, 28]</sup>. Two further trials <sup>[27, 30]</sup> found similar knowledge gains across 356 357 ethnicities, even though Gordon et al.<sup>[27]</sup> suggest – without a statistical test – that 358 359 knowledge improved more in non-Hispanic whites than in other non-African American racial/ethnic groups. A seventh trial did not show any knowledge effect <sup>[24]</sup>. 360 361 Interventions were equally effective for white and other ethnic groups with regard to decisional conflict and SDM<sup>[6, 30]</sup> (*Figure 3 B-C*). A study with high risk of bias also 362 suggested equal effects with regard to behavioural intention <sup>[28]</sup>. Singh et al. <sup>[22]</sup>, 363 however, suggest advantages for whites in the effects on informed choice and 364 365 decisional conflict, thereby indicating a negative association (*Figure 3 B*). 366 Although this finding for language preference was confirmed in the same study, 367 participants preferring Spanish, who had a presumably high overlap with the 368 Hispanic groups, were less represented in the sample, which might indicate a power 369 problem. 370 A high-risk-of-bias trial that looked at the effect of the intervention by language 371 preference also indicated that those who received the intervention in their preferred 372 language/mother tongue (English-speaking or bilingual participants) knew more than 373 those with some language barriers (Spanish-speaking participants)<sup>[28]</sup>. 374 375 Gender 376 No difference between women and men regarding intervention effects on knowledge, 377 decisional conflict and SDM was indicated by any study [6, 20, 21, 27] (Figure 3 A-C; 378
- **Supplement table S6**). Two studies <sup>[20, 21]</sup>, one <sup>[21]</sup> with high risk of bias, assessed baseline decisional conflict and knowledge. Only one study <sup>[6]</sup> tested the respective interactions with gender.
- 382383 Health literacy
- 384

It is made available under a CC-BY-NC-ND 4.0 International license .

385 One study showed higher decision-relevant knowledge with intervention for those with adequate, moderate and inadequate literacy skills <sup>[27]</sup>, but neglected to report 386 the interaction between these groups (Supplement 2 – table S7). Two studies [6, 30]387 388 that observed the interaction between having a low or typical HL with the intervention 389 could not reveal differences in knowledge (*Figure 3 A*). However, the statistical 390 power does not seem to be sufficient to detect such an interaction if it exists. In one 391 trial with high risk of bias, people with high literacy skills appeared to achieve greater knowledge scores than did those with lower literacy <sup>[21]</sup>. Each intervention was equally effective for SDM <sup>[6, 23]</sup> and decisional conflict <sup>[6, 22, 30]</sup> in studies of people with 392 393 394 low and typical HL (Figure 3 B-C). 395 396 Numeracy 397

Knowledge was suggested to increase more for those with medium or high numeracy scores than for those with lower scores in one trial with high risk of bias <sup>[21]</sup> (*Supplement 2 – table S7*). Two further studies <sup>[6, 30]</sup> do not support this unambiguously in their comparisons of groups with low vs. typical numeracy (*Figure* **3** *A*). In one study <sup>[6]</sup>, there was no adjustment for multiple testing despite 80 comparisons, while both studies may not have been adequately powered to test for the interaction of numeracy with the intervention effects.

For decisional conflicts, one trial <sup>[22]</sup> showed that, compared to usual care, the
 intervention was effective only for people with higher numeracy skills, which
 indicates a disparity increase (*Figure 3 B*). No difference in terms of both decisional
 conflict and SDM could be observed in the two further trials considering numeracy <sup>[6,</sup>]

409 <sup>23]</sup> (*Figure 3 B-C*).

410

411 SES

412

Intervention effects by socioeconomic factors have been investigated with the help of the SES (two studies <sup>[7, 30]</sup>), income (four studies <sup>[6, 22, 27, 30]</sup>) and employment status 413 414 (one study <sup>[27]</sup>) (Supplement 2 - table S8). Durand et al. <sup>[7]</sup> found that the difference 415 416 in decision-relevant knowledge after an effective intervention between those with lower and higher SES was smaller than in the control group (Figure 3 A). The other 417 study could not confirm that finding <sup>[30]</sup>. Nor did four further studies, indicating similar 418 knowledge gains across a broad income spectrum <sup>[6, 27, 30]</sup> (below 25k, below 65k, 419 above 65k US dollars per year) and independent of employment status <sup>[27]</sup>. None of 420 the studies <sup>[6, 7, 22, 30]</sup> found an effect on decisional conflict and SDM. Furthermore, no 421 difference was found between people with lower and higher SES <sup>[7, 30]</sup> in terms of 422 423 intervention effects on decision concordance, decisional conflict, SDM and treatment 424 choice. Nor could an interaction effect of income with interventions on decisional 425 conflict and SDM be confirmed <sup>[6, 30]</sup>. Only Singh et al. <sup>[22]</sup> found largest effectiveness on decisional conflict on those who reported lowest annual income (<40k). Across all 426 427 studies we found, this is the only evidence that an EBHI/DA-intervention – and, more 428 generally, any health information intervention - can reduce disparities in improving 429 decisional conflict (Figure 3 B). Overall, only economic indicators of inequality 430 revealed positively associated intervention effects. 431

438 Discussion

- 439440 Principal findings
- 441

442 Our systematic review reveals that inequity-producing factors are rarely considered 443 in effectiveness studies of EBHI/DAs. Included trials took into account at least one 444 factor as according to PROGRESS-Plus, but looked at the effect only in subgroup 445 analyses. The designs were heterogeneous, with few directly testing the association 446 between intervention effects and the disadvantage status, and few assessing 447 baseline levels of the respective outcomes. Sample sizes were often small, and for 448 many of the subgroups, few trials could be identified that provided evidence to draw 449 conclusions about effectiveness and/or the data were poorly reported. 450 In terms of knowledge, not everyone benefits equally, which is a key endpoint for 451 informed decision-making and SDM. People who were considered disadvantaged 452 because of their ethnicity (e.g. African Americans, Latinas, or other racial/ethnic 453 groups) or language in at least one study attained less knowledge in most studies, 454 which may have prevented the identification of asymmetries in both knowledge 455 acquisition and other outcomes. For decisional conflict, ethnic groups seem to have 456 benefitted equally in three out of four studies, lower and higher health numerates did 457 so in three identified studies, men and women in two identified studies, lower and 458 higher educated in two and younger and older age groups in one study. One of three 459 identified studies analysing numeracy and one out four studies analysing ethnicity 460 respectively showed a disadvantage for low numerates and non-whites in terms of 461 decisional conflict by the intervention. One of three trials analysing SES showed that 462 knowledge inequalities between people of different SES can be reduced by providing 463 EBHI/DAs. No differences in the effect for SDM by ethnicity, education, gender, 464 income, HL or numeracy could be identified across all three studies. Again, however, 465 because only few studies were available and this effect was only considered in 466 subgroup analyses with presumably inadequate power, asymmetries across 467 inequality factors may have not been recognised.

468

#### 469 Strengths and limitations

470

471 Through our research with the best available evidence, it has become clear that

inequity-producing factors were rarely considered in planning the evaluation and that

473 methodological approaches were not sufficient to make statements about the effect

- 474 between and within different groups.
- 475 Potential limitations: First, despite our efforts to search extensively for RCTs of
- 476 EBHI/DAs that evaluated the effectiveness in different social groups, our search
- 477 possibly missed relevant RCTs that met our inclusion criteria. Studies may not have
- 478 been identified in the title-abstract screening, because the effect of inequity-
- 479 producing factors was often only analysed in subgroups or mentioned in the
- 480 discussion only.
- 481 Our focus on RCTs may have neglected observational evidence that is more
- 482 inclusive of disadvantaged subgroups. Because most studies made no assumptions
- 483 about possible differences in effectiveness due to their retrospective analysis of

484 social factors, we did not define a priori a classification of disadvantaged or not485 disadvantaged.

Having also included trials without information prepared according to quality criteria for DAs <sup>[4]</sup> and not specifying a minimum requirement in the study protocol for those studies, we subsequently specified that trials with non-EBHI had to report at least the benefits and harms. However, we did not assess the quality of the individual DAs and instead relied on the statement that the DAs had been developed according to certain criteria. Thus, some of the DAs may not meet the highest quality standards of EBHI/DAs.

493

#### 494 **Comparison with other studies**

495

496 Unlike previous systematic reviews, ours focused on systematically assessing and 497 analysing the effectiveness of EBHI and DAs between and within patient subgroups. A systematic review from the Cochrane Review versions on the effectiveness of DAs 498 that included studies until 2021 <sup>[2]</sup> found that in only 12% of the included RCTs were 499 the needs of people with low HL or other disadvantaged groups considered in the 500 design and testing of DAs <sup>[11]</sup>, thereby suggesting differences in the degree of 501 502 effectiveness between and within patient subgroups. However, the review did not investigate this. A systematic review from 2016 [32] found that just 17 out of 39 503 504 included RCTs in the US included disadvantaged people while developing DAs on 505 cancer screening and treatment. Only 14 of the included studies investigated the 506 effect of DAs in disadvantaged groups (mainly by education and HL), most of them 507 for one specific group and few for and between different social groups <sup>[32]</sup>. 508 Furthermore, two systematic reviews found that SDM interventions improve for 509 example knowledge, informed choice and SDM for disadvantaged patients (e.g. 510 lower literacy, education and socioeconomic status) – particularly when tailored to the needs of disadvantaged groups <sup>[5, 33]</sup>. But the authors note the lack of evidence 511 512 on the effectiveness of decision-making interventions for disadvantaged people 513 compared with non-disadvantaged people, which was our focus. Other systematic 514 reviews examined DA evaluation studies with a particular focus on a group considered disadvantaged (e.g. people with low literacy <sup>[34]</sup>, older people <sup>[35]</sup> or people with racial or ethnic minority background <sup>[36, 37]</sup>) or focused on disadvantaged 515 516 populations, but for SDM interventions in general or multicomponent interventions<sup>[6, 33, 37]</sup>. 517 518

519

#### 520 Implications and future research

521

522 Only two studies found positive associations and three studies found negative 523 associations between intervention effectiveness and disadvantaged group status in 524 terms of SES and ethnicity/numeracy. On the one hand, overproportional decision-525 making benefits in those with lower SES may indicate a kind of "catch-up effect" and 526 a promise of enabling access to evidence-based health communication for those 527 groups. Disproportionately low benefits of those with low numeracy or an 528 underrepresented ethnic background, on the other hand, may reflect disregard of 529 health communication development standards for addressing difficulties with 530 numbers and language. Nevertheless, advantaged and disadvantaged patients 531 appear to benefit equally from EBHI/DAs. Given the small number of trials and the 532 fact that the effect was considered solely in subgroup analyses, which are likely to be 533 underpowered, asymmetries between factors of inequality may not have been

detected by the existing designs. Future research should therefore take better
 account of critical inequality factors when evaluating EBHI and DAs to contribute to
 more equitable health care.

537

#### 538 Conclusion

539

540 Due to the small number of studies and their methodological and qualitative 541 limitations, there is limited evidence on whether EBHI and DA contribute to good 542 healthcare for all patients or whether they benefit only certain subgroups of patients. 543 More attention should thus be paid to the methodological requirements to fully 544 capture potential effects of the diversity of the target groups. This is the only way to 545 prove and reduce inequalities in informed decision-making and ultimately ensure 546 appropriate and equitable health care.

# 549 **Contributions** 550

551 CE, JH and FGR conceptualised and designed the systematic review. CE, JH, CW

and FGR screened the studies and extracted the data for different updates of the

553 systematic review. CE and FGR analysed the results. CE drafted the manuscript and

554 made the revisions. CW, JH and FGR critically revised the manuscript. All authors 555 finally approved the manuscript. CE is the guarantor for this review.

556 We acknowledge Carolin Harder (CH), Chiara Müller (CM), Donja Ameri (DA),

557 Pauline Brunner (PB) and Julia Beckhaus (JB) for their research support (study

558 screening, data extraction and risk of bias assessment).

559

# 560 **Data availability statement**

561

562 Most of the data and analyses are available in supplementary files. Additional data 563 are available on request from the corresponding author.

564

# 565 Ethics statements

566

567 No ethics approval was required for this systematic review. Patient consent for
 568 publication was not applicable.
 569

# 570 Funding

571

This research received no specific grant from any funding agency in the public,
commercial or not-for-profit sectors.

# 575 **Competing interests**

576

577 The authors declare that, in the conduct and reporting of this study, there were no 578 financial or other conflicts of interest.
