NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice.

34 **Abstract**

35 **Background:** Globally, more than 700 thousand people commit suicide annually. In Sweden, the yearly
36 incidence is between 1000 and 1500 people, which is higher than the global average. Understanding the
37 economic burden of suicide could help highlight the importance and urgency of finding more effective
38 treatments and preventative measures to help people suffering from suicidal thoughts and support studies
39 evaluating the cost-effectiveness of various interventions.

40
41 **Method:** This national population-based cross-sectional study estimated the indirect costs associated
42 with all suicides in Sweden between 2010 and 2019. Indirect costs were estimated using the human
43 capital approach. Data regarding average salaries and employment rates were extracted from publicly
44 available data in Sweden. Productivity loss was estimated over two time horizons, the year following
45 the suicide and over a lifetime horizon. Estimations were performed in total numbers for the yearly
46 cohorts as well as per person.

47
48 **Results:** Between 2010 and 2019, 1 406 to 1 591 suicides occurred every year in Sweden. In total,
49 approximately 26 500 productive life years are lost every year due to suicide. In 2019, the productivity
50 loss due to all suicides in Sweden was estimated to be 44 million euros over a one-year time horizon,
51 where 10 million euros are direct losses in local and regional authority taxes. Over a lifetime,
52 productivity losses amounted to 935 million euros. The corresponding estimations per person were 37
53 and 778 thousand euros respectively over a one-year and a lifetime time horizon. Over a one-year time
54 horizon, the productivity loss was highest in the older age groups.

55
56 **Conclusions:** This study provides valuable insights into the economic burden of suicide on Swedish
57 society. It underlines the potential economic benefits of effective suicide prevention, aligning with
58 previous research highlighting the substantial returns—both monetary and in terms of human well-
59 being—that successful prevention strategies can yield.

60
61 **Keywords:** Cost of illness, suicide, suicide prevention, public health

62 **Introduction**

63 More than 700,000 people commit suicide across the world annually (1), and between 1,000 and 1,500
64 people commit suicide per year in Sweden (2). The incidence of suicide is greater in Sweden than in the
65 rest of the globe, with 10.7 deaths compared to 9 deaths per 100,000 people on average (3). People aged
66 above 65 are more likely to commit suicide, followed by people aged between 45 and 64 years (2).
67 Among adults, men are 2.5 times more likely to commit suicide than women are, and in the 15- to 29-
68 year-old group, suicide is one of the leading causes of death (1). Suicide is classified as a major public
69 health problem, not only because a person dies prematurely but also because of its extensive implications
70 for family members, relatives, friends, and society at large. Although it is well known that mental health
71 issues such as psychotic disorders and mood and anxiety disorders are associated with an increased risk
72 for suicide, a recent meta-analysis estimated that the population attributable risk of mental disorders as
73 a whole was approximately 21% (4). This substantial proportion should not be downplayed, but it is
74 perhaps not surprising that most working-age individuals who die by suicide have no underlying mental
75 health disorder and have an occupation at the time of their death (5).

76
77 Previous research has shown that a large part of the costs attributed to suicide do not stem from direct
78 medical costs but rather from costs associated with the loss of labor production (6, 7). However, these
79 cost estimations are not based on complete national registries, introducing uncertainty in the estimations.
80 While Sweden has some of the world's most comprehensive individual-level registries, it allows for
81 encompassing estimations of the burden of suicide.

82
83 Understanding the economic burden of suicide could help highlight the importance and urgency of
84 finding more effective treatments and preventative measures to help people suffering from suicidal
85 thoughts and support studies evaluating the cost-effectiveness of various interventions. In addition, how
86 the economic burden is spread across different actors in society is important to policy makers and for
87 budget allocation because it provides arguments for the potential economic benefit for different actors
88 to invest in preventive measures. The aim of this study is to estimate the economic burden related to
89 indirect costs that suicide has imposed on Swedish society between 2010 and 2019.

90 **Methods**

91 This national population-based cross-sectional study estimated the indirect costs associated with all
92 suicides in Sweden between 2010 and 2019. Indirect costs were estimated using the human capital
93 approach. This study was conducted in accordance with the STROBE reporting guidelines (see
94 Supplementary Table 1). All data used in the study have been aggregated, publicly available data. Hence
95 no ethical approval or consent has been necessary.

96

97 ***Data collection***

98 Data regarding the number of suicides committed in Sweden per year were acquired from the Swedish
99 National Cause of Death Registry, which is held by the Swedish National Board of Health and Welfare.
100 The data were accessed for research purposes from 2010 to 2019. Authors did not have access to
101 information that could identify individual participants during or after data collection. To approximate
102 the true incidence of suicides in Sweden, suicide deaths classified as ICDs X60-X84/E950-E959 were
103 combined with so-called uncertain suicides, i.e., ICD Y10-Y34/E980-E989, between 2010 and 2019.
104 The data were divided into yearly cohorts based on the year when the suicide occurred. Each yearly
105 cohort was further subgrouped based on sex and age.

106

107 The parameters included in the calculations for productivity loss are outlined in Table 1. These included
108 the average salary in Sweden retrieved from Statistics Sweden and data on average employment, social
109 fees, the pension rate and vacation compensation. Furthermore, Table 1 displays the division of income
110 taxes paid to the regional and local authorities.

111

112 *Table 1. Parameters included in the calculations.*

Parameter	Estimation	Sources
Average monthly salary in Sweden 2019	3 100 €	(8)
Average employment rate in Sweden 2019	67,3%	(9)
Social fees	31,42%	(10)
Pension fee	4,5%	(11)
Vacation compensation	12%	(12)

Taxes on salary compensation	Local level authority tax	20,70%	(13)
	Regional level authority tax	11,49%	(13)
	Funeral fee	0,23%	(13)
Conversion from SEK to Euros		1 SEK = 0,087 €*	(14)

113 *Exchange rate on the 26th of November 2023
114

115 *Cost analysis*

116 *Productivity loss*

117 The human capital approach was used to estimate the productivity loss that occurs due to premature
118 death following completed suicide. Years of productive life lost were estimated by subtracting the age
119 when the suicide occurred from the retirement age in Sweden and including the average mortality rate
120 for each age (probability of surviving another year).
121

122 Productivity loss was calculated over two different time horizons, the year following the death and over
123 the lifetime. Estimations were performed in total numbers for the yearly cohorts as well as per person.
124 Productivity loss was further estimated over five different age groups, 18-24, 25-34, 35-44, 45-54 and
125 55-67, both over a one-year time horizon and over a lifetime. The parameters included in the estimations
126 were the average employment rate in Sweden, the average monthly salary, social fees (31.42% of the
127 monthly salary), vacation compensation (12% of the monthly salary) and the pension fee paid by
128 employers (4.5% of the monthly salary); see Table 1. All calculations were performed on a yearly basis.
129

130 Due to premature death and loss of productivity, individuals are unable to contribute to the tax system
131 at large. Taxes in Sweden are divided into state-, regional- and local-level authorities. Most of these
132 taxes are paid by individuals through salary compensation and value added tax (VAT) on goods and
133 services purchased and by employers through social and pension fees. Tax loss (part of the total indirect
134 cost) was estimated as the percentage of the monthly income that would have gone to taxes, with a
135 regional tax of 11.49% of the monthly income and a local authority tax of 20.70% of the monthly salary.
136

137 *Discounting, Economic Growth, and Inflation*

138 For the lifetime horizon, future costs were discounted at an annual rate of 3%, which is recommended
139 for health economic evaluations in Sweden (15). This discount rate accounts for the time preference of
140 money, reflecting the principle that costs incurred in the future are less valuable than costs incurred
141 today. Additionally, future economic growth rates and inflation were considered by adjusting the
142 average salary growth rate based on historical data from Statistics Sweden. The average annual growth
143 rate of salaries was assumed to be 2%, and the inflation rate was assumed to be 1.5%, based on historical
144 trends.

145

146 *Net vs. Gross Salary*

147 The salary data used in this study represent gross salaries, which include all taxes and social fees. The
148 salaries were adjusted for age-specific variations. This approach provides a comprehensive estimate of
149 the economic impact of suicide by capturing the total earnings lost, including the portions that would
150 have been paid as taxes and social contributions.

151

152 *Sensitivity analysis*

153 In the sensitivity analysis, the employment rate was varied to 40 percent, 50 percent, 60 percent, 70
154 percent, and 80 percent to account for the possible difference in productivity for this specific cohort.

155

156

157 **Results**

158 Between 2010 and 2019, 1 406 to 1 591 suicides occurred every year in Sweden. The average age of
159 people who commit suicide during these years was approximately 50 years. In total, approximately
160 26 500 productive life years were lost every year due to suicide (supplementary table 2).

161

162 *Total cost*

163 Between 2010 and 2019, the total cost of suicide related to indirect costs varied between 32 million and
164 44 million euros over a one-year horizon and between 795 million and 935 million euros over a lifetime

165 horizon. The indirect costs per person varied between 28 thousand and 37 thousand euros over a one-
166 year horizon and between 708 thousand and 778 thousand euros over a lifetime horizon (Table 2).

167 *Table 2. Total forgone costs due to suicide over a one-year time horizon and a lifetime horizon*

Year	Productivity losses		Productivity losses per person	
	1 year	Lifetime	1 year	Lifetime
2010	32 000 000 €	795 000 000 €	28 000 €	708 000 €
2011	33 000 000 €	830 000 000 €	30 000 €	758 000 €
2012	37 000 000 €	865 000 000 €	31 000 €	725 000 €
2013	38 000 000 €	926 000 000 €	31 000 €	760 000 €
2014	38 000 000 €	909 000 000 €	32 000 €	769 000 €
2015	38 000 000 €	891 000 000 €	32 000 €	743 000 €
2016	38 000 000 €	834 000 000 €	34 000 €	751 000 €
2017	41 000 000 €	883 000 000 €	35 000 €	769 000 €
2018	44 000 000 €	926 000 000 €	37 000 €	769 000 €
2019	44 000 000 €	935 000 000 €	37 000 €	778 000 €

168 *Exchange rate of Swedish krona to Euros on the 26th of November 2023. 1 SEK = 0,087 €*

169

170 *Age groups*

171 The productivity loss between different age groups was estimated (supplementary table 3) both in total
172 and per person. Over a one-year period, the highest total and per-person costs were found for the 45- to
173 54-year-old age group, followed by the 35- to 44-year-old age group. The cost per person for the 45- to
174 54-year-old age group ranged between 54 thousand euros and 56 thousand euros. The lowest costs are
175 found in the 18-24 age group; in this age group, the costs vary between 17 thousand euros and 19
176 thousand euros per person.

177 Over a lifetime horizon (Table 3), the highest cost is found for the 18-24 age group per person. For this
178 group, the costs vary by approximately 20 million SEK. The lowest costs are found in the 55- to 67-
179 year-old age group, where the costs vary by approximately 3 million SEK.

180

181 *Table 3. Total cost per person for different age groups over a lifetime horizon*

Age group	Productivity loss over a lifetime	Productivity loss per person over a lifetime
18-24	227 000 000 €	1 600 000 €
25-34	411 000 000 €	1 500 000 €
35-44	262 000 000 €	1 200 000 €

45-54	192 000 000 €	720 000 €
55-67	72 000 000 €	280 000 €

182

183 *Loss of taxes 2019*

184 As part of the indirect costs of suicide in 2019, the losses in taxes for different sectors amounted to
185 approximately 6.4 million euros for the local authorities and 3.6 million euros for the regional
186 authorities. The lost social fees that would have been transferred to the state for the cohort that passed
187 away in 2019 amount to 14.5 million euros.

188

189 *Sensitivity analysis*

190 In the sensitivity analysis, the employment rate varied between 40 and 80%. The average employment
191 rate in Sweden is approximately 67 percent. In 2019, the indirect costs over a one-year period varied
192 between 20 thousand euros and 40 thousand euros per person. Over a lifetime, the costs varied between
193 428 thousand and 856 thousand euros. In the different age groups, the indirect cost (per person) over a
194 one-year period varied between 15 thousand – 31 thousand euros (age group 18-24), 18 thousand – 37
195 thousand euros (age group 25-34), 22 thousand – 44 thousand euros (age group 35-44), 23 thousand –
196 46 thousand euros (age group 45-54) and 22 thousand – 45 thousand euros (age group 55-67). Over a
197 lifetime horizon, the indirect costs due to suicide (per person) varied between 734 thousand – 1.5 million
198 euros (age group 18-24), 655 thousand – 1.3 million euros (age group 25-34), 507 thousand – 1 million
199 euros (age group 35-44), 323 thousand – 647 thousand euros (age group 45-54) and 131 thousand – 262
200 thousand euros (age group 55-67).

201

202 **Discussion**

203 This study provides valuable insights into the economic burden of suicide on Swedish society. The
204 findings reveal substantial financial implications, with suicide accounting for significant amounts in
205 terms of both one-year and lifetime estimates. In 2019, the total productivity losses amounted to
206 44 000 000 € yearly. Some of these losses fall on the state (14.5 million euros), regional (3.6 million
207 euros) and local (6.4 million euros) authorities due to tax losses.

208

209 The costs per person, though varying across different studies, offer a comparative perspective. A study
210 from Finland estimated substantially lower costs per person over a lifetime perspective than reported in
211 this study (322,928 euros compared with 729,575 euros). The reasons for this are the different methods
212 used in the estimation. We estimated indirect costs based on loss of production, whereas Solin and
213 colleagues measured costs only in terms of lost tax returns in Finland [7]. In contrast, an Australian
214 study which estimated indirect costs of suicide for individuals ages 24 and younger, found a similar
215 yearly indirect cost, 1 700 000 euros, compared to our estimates of 1 600 000 euros for individuals aged
216 24 and younger [15].

217

218 This study underlines the potential economic benefits of effective suicide prevention, aligning with
219 previous research highlighting the substantial returns, both monetary and in terms of human well-being,
220 that successful prevention strategies can yield. The economic foundation provided by this study can
221 provide powerful support for knowledge-based decision-making as well as for the development and
222 evaluation of preventive measures.

223

224 The focus on costs associated with loss of productivity excludes other substantial costs related to suicide,
225 such as emergency response, medical care, family members' incapacity for work and/or potential
226 treatment costs related to complicated grief and other disorders of relatives, costs related to the transport
227 system (e.g., in railway, subway and motorway suicides) and property damage. Both Kinchin et al. and
228 Solin et al. included costs related to direct medical or emergency expenditures (7, 16). However, the
229 direct cost only accounted for a fraction of the total cost of suicide, and the other unrelated costs are also
230 likely to be only a fraction of the total costs related to suicide. In the Kinchin et al. study, health-care
231 costs during suicide-related emergencies only accounted for 0.01% of the total cost, and in the study by
232 Solin et al., the productivity loss from deceased people accounted for approximately 70%. Similarly, a
233 study by Segar et al. estimating the costs of suicides in France found that the direct costs of completed
234 suicides are very small compared to indirect costs, with direct costs accounting for only 0.4%,
235 highlighting the significant economic burden of productivity losses and other societal impacts (17).

236

237 In this study, we have chosen to focus exclusively on completed suicides for several reasons. Firstly,
238 completed suicides are clearly defined and recorded in national databases, providing us with accurate
239 and reliable data, which minimizes the risk of inaccuracies and uncertainties in our analyses. Secondly,
240 completed suicides have a direct and measurable economic impact on society, including lost
241 productivity and tax revenues. By focusing on these, we can clearly demonstrate the economic burden
242 and the need for effective preventive measures. Thirdly, policymakers and decision-makers require
243 concrete and specific data to make informed decisions about resource allocation and the development
244 of preventive strategies. By focusing on completed suicides, we provide information needed to prioritize
245 preventive interventions that may save lives. By limiting our scope to completed suicides, we can
246 conduct a more focused and in-depth analysis. Lastly, previous studies in this field have also focused
247 on completed suicides (7, 16). By doing the same, the results are comparable to previous research and
248 contribute to a more coherent and comparable knowledge base.

249

250 This study has several strengths. First, it uses data from high-quality nationwide registries, which
251 eliminates selection bias and ensures that all cases of suicide in Sweden are included in the dataset.
252 Second, the complete dataset allows for a comprehensive analysis of the data, which is a major strength
253 of the study. Third, the assumptions made in the study are conservative, which means that the results
254 are probably an underestimation of the total cost burden.

255

256 The study also has some limitations. One limitation is the decision to only include individuals aged 18-
257 67 years, based on presumed employment, which raises concerns about the exclusion of a significant
258 portion of the population. The age for retirement in Sweden is 67, and it is common to assume that
259 income and tax-generating productivity are subsequently reduced to zero. However, this group,
260 particularly the 85+ group, has the highest suicide risk among all age groups, and most individuals who
261 retire in Sweden continue to contribute to unpaid work. However, the consequence of using the human
262 capital approach for estimating the costs of suicide is the exclusion of this group from the analysis.
263 Another limitation is the precision of our estimates. The Swedish nation-wide registers used as data

264 inputs were on an aggregate level; hence, the employment and salary for each individual were not
265 available, and average estimates had to be used. These limitations should be kept in mind when
266 interpreting the findings of this study. Finally, we included both certain and uncertain suicides in the
267 estimation of productivity losses. Some of the uncertain suicides may not have been suicides, which
268 may have led to an overestimation of the total indirect costs of suicide.

269

270 **Conclusion**

271 This study sheds light on the economic burden of suicide in Sweden, emphasizing the need for
272 comprehensive preventive strategies. to the study provides a nuanced understanding of the economic
273 implications of completed suicides, laying the groundwork for future research and policy discussions in
274 the realm of suicide prevention.
