43 **Abstract**

44 An immunosuppressive tumor microenvironment limits the efficacy of immunotherapy, thus patients
45 with MSS and pMMR mCRC often face great challenges. In this phase II trial, patients received
46 Gamma Knife SBRT combined with Tislelizumab . P Biomarker analysis was performed pre- and
47 post-treatment . From November 2022 to July 2024, 13 of 20 patients achieved PR, 6 achieved SD.
48 mPFS was 10.7 months (95% CI, 6.4-15.0). With no grade 4 events noted, common adverse events
49 included nausea (65%), anemia (55%), and fatigue (45%). For patients who had not responded to
50 first and second-line therapies, the combo of Gamma Knife SBRT and tislelizumab showed high
51 efficacy and reasonable safety. Significant post-radiotherapy improvements in the tumor's
52 immunosuppressive microenvironment. These results imply that patients with pMMR/MSS/MSI-L
53 mCRC who were unresponsive to the first and second-line chemotherapy, Gamma Knife SBRT with
54 tislelizumab provides a safe and powerful later-line treatment alternative.

55

56 **Keywords:** Gamma Knife Stereotactic body radiation therapy; mismatch repair-proficient;
57 tislelizumab; Metastatic colorectal cancer; Immune checkpoint inhibitors; PD-L1.

58

59 **Statement of significance**

60 This study offers a safe and powerful option for pMMR/MSS/MSI-L mCRC patients fail to first and
61 second-line chemotherapy. And discover Gamma Knife SBRT contributed to potentially converting
62 the suppressive "cold" tumor immune microenvironment into an activated "hot" microenvironment
63 conducive to immunotherapy efficacy in pMMR CRC.

64

65

66 **Introduction**

67 Colorectal cancer continues to represent a significant threat to life. As reported in the 2020 Global
68 Cancer Statistics, colorectal cancer accounts for 10% of all cancer cases, ranking third in incidence,
69 while its mortality rate is 9.4%, second only to lung cancer (1,2). Especially, 20% of newly diagnosed
70 colorectal cancer patients present show metastases, and 40% have recurrence and metastases after
71 local treatment (3). The FOLFOX/FOLFIRI chemotherapy regimen, which comprises oxaliplatin,
72 5-fluorouracil, and irinotecan is the mainstay of clinical treatment for metastatic colorectal cancer
73 (mCRC). For patients harboring wild-type RAS and BRAF, the addition of the epidermal growth factor
74 receptor (EGFR) inhibitor cetuximab is recommended(4,5). For patients with RAS mutations, the
75 anti-angiogenic agent bevacizumab is advised. Nevertheless, RAS-mutant patients exhibit poorer
76 prognoses and shorter survival times compared to their wild-type counterparts (6,7). The efficacy of
77 chemotherapy in combination with targeted therapy remains suboptimal (7).

78

79 The development of immune checkpoint inhibitors (ICIs) transforms cancer immunotherapy (8).
80 Particularly CRCs with mismatch repair deficiency (dMMR) and high microsatellite instability (MSI-H)
81 show a strong response to ICIs (9). But most CRC cases are either microsatellite-stable/low
82 microsatellite instability (MSS/MSI-L) or mismatch repair-profile (pMMR), which reduces the efficacy
83 of immunotherapy in a significant number of mCRC patients (9). Chemotherapeutic agents can
84 cause immunogenic cell death in tumors, thus coordinating with ICIs improves anti-tumor efficacy
85 (10). Additionally, anti-angiogenic therapies targeting VEGFR facilitate the normalization of tumor
86 vasculature and promote immune cell infiltration, subsequently amplifying immune-mediated tumor
87 eradication (11). Clinical studies, however, have revealed that t combining mFOLFOX6 or other

88 chemotherapy regimens with anti-VEGF, anti-EGFR, and ICIs does not produce better clinical
89 outcomes in mCRC (12,13). Consequently, identifying alternative strategies to augment the efficacy
90 of immunotherapy remains a pivotal objective in the field of cancer immunotherapy in
91 pMMR/MSS/MSI-L mCRC.

92

93 Stereotactic body radiation therapy (SBRT), effectively targets and eradicates tumor cells with
94 high-dose radiation (14). Although traditional radiotherapy is sometimes linked with
95 immunosuppressive effects (15), SBRT's exact targeting can expose tumor neoantigens, mobilize
96 and activate immune cells, increase their infiltration into the tumor, and improve the tumor immune
97 microenvironment (16,17). The Gamma Knife is a principal modality in SBRT, employing gamma
98 rays generated by cobalt-60 to deliver a single, high-dose focused irradiation to the target lesion. The
99 Gamma Knife provides several benefits over conventional radiotherapy, including hiexact
100 stereotactic targeting, increased delivery dose to the lesion, prevention of accelerated repopulation
101 of tumor cells, and better local control rates of tumors(18). Our team firstly observed a case with
102 pMMR-type mCRC who exhibited local recurrence and distant metastasis following first-line and
103 second-line chemotherapy combined with targeted therapy(19). After undergoing gamma knife SBRT
104 followed by tislelizumab treatment, intrahepatic metastatic lesions were reduced and stabilized, the
105 patient showed a partial response (PR) with notable reduction of recurrent lesions in the rectal wall
106 and stabilization of intrahepatic metastases, so extending the progression-free survival (PFS)
107 exceeded beyond 3 months (19). These findings suggest that Gamma Knife SBRT might improve
108 ICBs sensitivity in mCRC.

109

110 The results of a phase II clinical trial assessing the combination of Gamma Knife SBRT combined
111 with tislelizumab as a later-line therapy in patients with pMMR/MSS/MSI-L mCRC are presented in
112 this report together with safety and efficacy. NanoString assay for transcriptome analysis was
113 employed to elucidate changes in the tumor immune microenvironment during the combined
114 treatment, offering insights into the therapeutic potential and mechanistic underpinnings of this
115 integrated approach.

116

117 **Results**

118 **Patients**

119 In this clinical trial, twenty patients with pMMR/MSS/MSI-L tumors refractory to first or second-line
120 treatment were enrolled. The cohort comprised 15 males and 5 females, with ages ranging from 47
121 to 77 years. Predominantly, the primary tumors were located in the left colon and rectum (17/20,
122 85%), with the liver being the most common site of metastasis, followed by the lung (3/20)(**Table 1**).
123 Flowchart of therapeutic regimen and flow diagram of enrolled participants in the study were shown
124 in **Figure 1A** and **Figure 1B**.

125

126 Molecular profiling revealed RAS mutations in 11 patients (55%), with 5 exhibiting KRAS mutations
127 and 6 presenting NRAS mutations. PD-L1 expression was assessed in 18 patients, 12 (60%)
128 patients had combined positive score (CPS) ≤ 1 . Tumor mutation burden (TMB) data were
129 available for 8 patients, with a median TMB of 4.62 mutations/Mb (IQR 3.08-8.97). Notably, only one
130 patient exhibited a TMB > 10 mutations/Mb (**Table 1**).

131

132

133 **Efficacy**

134 In our cohort of 20 patients meeting inclusion criteria, 13 (65%) achieved a partial response (PR),
 135 and 6 (35%) maintained stable disease (SD), resulting in a robust disease control rate (DCR) of 95%
 136 (**Table 2**). Patients with liver metastases achieved 92.9% DCR, and patients with metastases in
 137 non-liver locations notably achieved a remarkable 100% DCR, only 1 patient with liver metastases
 138 experienced disease progression (PD) (**Figure 2A**). As of the data cutoff date, 7 patients remained
 139 on maintenance treatment, and 1 patient underwent surgery due to disease progression (**Figure 2A**).
 140 Remarkably, 3 patients refractory to first-line treatment responded to SBRT combined with
 141 tislelizumab, achieving rapid regression to NED status, with durations ranging from 6 to 18 months
 142 before progression. Encouragingly, 1 patient remains in a state of NED, under ongoing monitoring
 143 (**Figure 2A**).

	All patients (N = 20)	Liver metastasis (N = 14)	Other metastasis (N = 6)
Best overall response			
Complete response (CR), n (%)	0 (0%)	0 (0%)	0 (0%)
Partial response (PR), n (%)	13 (65%)	8 (57%)	5 (83%)
Stable disease (SD), n (%)	6 (30%)	5 (36%)	1 (17%)
Progressive disease (PD), n (%)	1 (10%)	1 (7%)	0 (0%)
ORR, n (%), 95% CI	13 (65%, 40.8-84.6%)	8 (57.1%, 28.9-82.3%)	5(83.3%, 35.9-99.6%)
DCR, n (%), 95% CI	19 (95%, 75.1-99.9%)	13 (92.9%, 66.1-99.8%)	6(100%, 54.1-100%)

Abbreviations: ORR, objective response rate; DCR, disease control rate.

Table 2: Efficacy outcomes.

144

145 Most patients exhibited favorable survival outcomes throughout the treatment (**Figure 2B**), and
146 median progression-free survival (PFS) was 10.7 months (95% CI, 6.4, 15.0) (**Figure 2C**).
147 Additionally, a comparative survival analysis included 23 patients who underwent first and
148 second-line treatment and Gamma Knife SBRT without immunotherapy, revealing a median PFS of
149 6.7 months (95% CI, 5.6, 7.0), this data shown Gamma Knife SBRT combined with tislelizumab as
150 later-line treatment prolong PFS in mCRC (Log-rank test = 5.638, P = 0.0176) (**Figure 2D**). These
151 findings suggest Gamma Knife SBRT combined with tislelizumab can effectively inhibiting mCRC
152 progression.

153

154 In light of the abscopal effect of radiotherapy, we extended our observations beyond the lesions
155 directly targeted by stereotactic radiotherapy to include non-irradiated lesions. Imaging examinations
156 revealed significant tumor regression in both the irradiated target lesions (**Figure 2E, F**) and the
157 non-irradiated lesions (**Figure 2E, G**) following Gamma Knife SBRT combined with tislelizumab.
158 These findings suggest that SBRT not only impacts the irradiated lesions but also sensitize distant
159 metastatic sites for ICBs through the abscopal effect, thereby enhancing the systemic antitumor
160 response when combined with immunotherapy.

161

162 Safety

163 All 20 enrolled patients received the assigned treatment regimen, with safety assessments
164 conducted every three treatment cycles. Treatment-related adverse events (TRAEs) and

165 immune-related adverse events are summarized in **Table 3**. Predominantly, patients experienced
 166 mild to moderate adverse events, with the most common being nausea (65%), anemia (55%),
 167 electrolyte disturbances (55%), fatigue (45%), and anorexia (35%). Notably, only two patients
 168 experienced grade 3 events of increased blood bilirubin, while no grade 4 adverse events were
 169 reported throughout the study period.

TEAEs, n (%)	Patient (N=20)				
	Grade 1	Grade 2	Grade 3	Grade 4	Any grade
Anemia	9 (45%)	2 (10%)	0	0	11 (55%)

Hypertension	0	0	0	0	0

Table 3: Treatment-emergent adverse events (TEAEs) since the initiation of protocol-specified treatment

170

171 **Identification of differentially expressed genes between responder and non-response groups**

172 To elucidate the impact of the tumor immune microenvironment on combination therapy outcomes,
173 we employed NanoString assay for transcriptome analysis of tumor samples obtained from 16
174 enrolled patients before and after treatment, totaling 32 samples (**Figure 3A**). Patients were stratified
175 into r responder (PR) and non-responder (non-PR) groups based on treatment outcomes. Gene
176 expression differential analysis between pre- and post-treatment samples within each group
177 identified significant alterations, detailed in the **Supplementary Data** and illustrated in **Figure 3B**.

178

179 Our findings highlighted notable up-regulation of key genes involved in antigen presentation (CD40,
180 TNFSF18, TNFSF4), immune checkpoint modulation (PDCD1LG2, CD274, IDO1, VTCN1), and T
181 cell activation pathways (TNFRSF9, CD28, ICOS, CD40LG, CD2, GZMK, ENTPD1, ITGAE) in the
182 responder group. Additionally, a diverse array of chemokine family genes (IL2, IL4, IL17A, CCR2,
183 CCL22) showed enhanced expression in PR group (**Figure 3B**). Furthermore, immune cell
184 abundance analysis based on 11 predefined immune cell types revealed significantly elevated levels
185 in the PR group compared to non-PR. included T cells, B cells, mast cells, macrophages, Dendritic
186 Cell (DC), Cytotoxic cells, NK CD56 cell, CD8 T cell, CD45 cell, Th1 cells and NK cell (**Figure 3C**).
187 This heightened immune activation in responders encompassed robust antigen presentation, T cell
188 activation, and co-stimulation processes crucial for effective immune-mediated tumor control.

189

190 Following the combination of stereotactic radiotherapy and immunotherapy, a striking reduction in

191 liver metastasis target lesions was observed in two patients compared to baseline To elucidate these
192 findings, we conducted CD8 and PD-L1 immunohistochemical staining on liver metastasis biopsy
193 specimens from one patient pre- and post-treatment (**Fig 3D-E**). The analysis revealed increased
194 infiltration of T cells and improved immune microenvironment following treatment, aligning with our
195 prior analytical findings.

196

197 **Additional immune signatures analysis in predicting tumor response**

198 We conducted gene expression analysis based on 12 predefined gene sets associated with
199 immunotherapy and prognosis (**Figure 4A**). Notably, samples from the responder group exhibited
200 higher expression of immune activation related genes compared to the non-responder group, include
201 effector T cells (T-eff), T cell-Inflamed, IFN- γ , cytotoxic, Cytolytic activity score (CYT), chemokines,
202 angiogenesis (AG), APC co-stimulation (APC co-sti), inflammation promoting (Inflam-pro), T cell
203 co-stimulation (T cell co-sti), parainflammation (parainflam) and tumor-infiltrating lymphocytes (TIL)
204 (**Figure 4A**).

205

206 Further compared the related-signature score, we found the responders had higher APC and T cell
207 co-stimulation signature scores compared with the non-responder group (**Figure 4B**). Moreover, the
208 responders had higher T cell-Inflamed, inflammation promoting and parainflammation signature
209 scores compared with the non-responder group (**Figure 4C**). Additionally, increased expression of
210 effector T cell, cytotoxicity, IFN- γ production, and cytolytic activity and TIL signature scores compared
211 with the non-responder group (**Figure 4D**).

212

213 Further functional insights into differential gene expression between responder and non-responder
214 groups were gained through gene ontology (GO) enrichment and Kyoto Encyclopedia of Genes and
215 Genomes (KEGG) pathway analyses. GO analysis highlighted enrichment in cytokine and
216 chemokine receptor activities, alongside increased T cell and leukocyte proliferation and activation
217 levels in responders (**Supplementary Fig 1A**). Correspondingly, KEGG analysis underscored
218 enrichment in pathways involving antigen processing and presentation, T cell receptor signaling,
219 chemokine interactions, and cytokine signaling (**Supplementary Fig 1B**). Notably, these results
220 indicated responders after combination of Gamma Knife SBRT and tislelizumab treatment will
221 enhancing tumor antigen presentation and T cell mediated immune response in pMMR/MSS/MSI-L
222 mCRC.

223

224 **Analysis on differential expression genes before and after treatment in the responders.**

225 To unravel the mechanisms driving tumor regression in the responder cohort, we conducted
226 comprehensive gene expression analysis before and after treatment, focusing on 7 gene groups
227 known for their potential inhibitory effects on immunotherapy. Post-treatment analysis revealed
228 significant reductions in exhausted T cells, Th2 cells, and Treg cells, indicative of a favorable shift
229 away from a suppressive immune microenvironment (**Figure 5A**). Tumor resistance mechanisms,
230 such as fibrosis and angiogenesis, play pivotal roles in limiting therapeutic efficacy(20,21). Initially,
231 evaluation of immunotherapy-related gene groups in partial responders versus non-responders
232 highlighted significantly higher angiogenesis scores in the former, albeit with no significantly
233 difference (**Figure 5B**). Recognizing potential biases from pooling samples pre- and post-treatment,
234 we conducted separate analyses within the responder group, expanding our gene set to include

235 fibrosis-related genes. The findings underscored substantial inhibition of both angiogenesis and
236 fibrosis within the tumor microenvironment following SBRT, targeted therapy, and immunotherapy
237 **(Figure 5C)**.

238

239 Further stratified analysis of non-responder samples before and after treatment revealed no
240 significant alterations in the expression levels of immunosuppression-related or
241 angiogenesis/fibrosis-related gene sets **(Supplementary Fig 2)**. These insights illuminate critical
242 pathways through which combined therapies modulate the immune landscape and enhance
243 treatment responses in pMMR/MSS/MSI-L mCRC.

244

245 **Discussion:**

246 By successfully reaching its main endpoint, this phase II trial shows that for combined Gamma Knife
247 SBRT with tislelizumab greatly increases progression-free survival (PFS) in pMMR/MSS/MSI-L
248 mCRC, resistant to first and second-line therapies. For this patient population, the combo treatment
249 has shown both safety and tolerability. By overcoming resistance to first treatment plans, our study
250 presents a creative therapy approach for those unresponsive to conventional treatments that offers a
251 suitable therapeutic option improving clinical outcomes.

252

253 Among the several cancers including nasopharyngeal carcinoma, esophageal cancer, liver cancer,
254 and lung cancer, Tislelizumab, a new PD-1 inhibitor, has been shown especially therapeutic efficacy.
255 Combining tislelizumab with chemotherapy has essentially extended PFS in patients across these
256 cancers (22-25). While immunotherapy has proven beneficial for some patients, metastatic colorectal

257 cancer (mCRC) presents unique challenges. Particularly in patients with MSS/pMMR tumors, which
258 are marked by low immunogenicity and great resistance to immunotherapy, tumor cells in mCRC
259 often evade immune detection and destruction (26). By directly targeting and destroying tumor cells,
260 Gamma Knife SBRT presents a potential solution by releasing a significant volume of tumor
261 neoantigens, and improving tumor immunogenicity, so optimizing maximizing the efficacy of
262 subsequent immunotherapy(27). Furthermore demonstrated to extend survival in non-small cell lung
263 cancer (NSCLC) with patients with brain metastases is the combination of Gamma Knife SBRT and
264 immunotherapy (28). Still underreported, though, is the possibility of Gamma Knife SBRT coupled
265 with ICIs to improve the response in pMMR/MSS/MSI-L CRC.

266

267 In our clinical observations, a notable therapeutic effect was achieved in a patient treated with
268 combined SBRT and immunotherapy. We hypothesize that the addition of tislelizumab following
269 SBRT could extend progression-free survival (PFS) compared to either modality alone. Tumor
270 microenvironment post-radiotherapy showed significant changes revealed by sequencing analysis of
271 tumor samples 'both before and after combined treatment. More precisely, the microenvironment
272 transitioned from an immunosuppressive, angiogenesis- and fibrosis-promoting state to an
273 immune-enhanced, angiogenesis- and fibrosis-attenuated state. Comparatively to non-responders,
274 responders expressed genes linked to antigen presentation, tumor inflammation, and
275 immune-mediated tumor killing more strongly. Further showing the activation of several signaling
276 pathways associated with tumor cell death, including NF- κ B, TNF, and JAK-STAT pathways was
277 enrichment analysis. Furthermore, immunotherapy targets such as PD-L1, showed an elevation,
278 which supports the possibility of efficient later immunotherapy. These findings substantiate our

279 hypothesis that patients with MSS-type mCRC resistant to first-line treatment could benefit
280 significantly from the combination of stereotactic radiotherapy and immunotherapy, with enhanced
281 immunogenicity and a more favorable tumor microenvironment facilitating improved therapeutic
282 outcomes.

283

284 This trial restrictions even if its outcomes show promise. First of all, our results could be biased as a
285 single-arm study devoid of a control group. Second, the limited sample size and single-center design
286 of the study lower its statistical power hence more robust conclusions depend on bigger studies.
287 Furthermore, even though general survival (OS) was examined, the follow-up duration was
288 insufficient to establish a reliable median OS. To address these limitations, a multi-center,
289 randomized controlled trial with a larger cohort and extended follow-up period is essential. This will
290 provide a more comprehensive evaluation of the efficacy and safety of combining Gamma Knife
291 SBRT and tislelizumab as a later-line therapy in pMMR/MSS/MSI-L mCRC patients.

292

293 Ultimately, for patients with pMMR/MSS/MSI-L mCRC who were unresponsive to first-line therapy
294 regimens, the combination of Gamma Knife SBRT with tislelizumab demonstrated a high disease
295 control rate (DCR) and manageable safety profile. Significant post-radiotherapy improvements in the
296 tumor's suppressive immune microenvironment, reduced fibrosis, normalized tumor vasculature, and
297 activation of the PD-1/PD-L1 checkpoint pathway revealed by biomarker analyses so improving the
298 efficacy of immunotherapy.

299 **Methods**

300 **Study design and participants**

301 This single-arm, phase II trial was conducted at the First Affiliated Hospital of Jinan University to
302 assess the antitumor efficacy and safety of a combined regimen consisting of SBRT and tislelizumab
303 in patients with pMMR/MSS/MSI-L-type metastatic colorectal cancer (mCRC). The study is
304 registered with ClinicalTrials.gov (identifier: ChicTR2200011777). Eligible patients, aged 18-75 years,
305 had confirmed metastatic colorectal cancer. MSS and RAS mutation statuses were determined
306 through gene sequencing, while clinical staging was based on imaging examinations and
307 intraoperative findings. A total of 20 patients were enrolled in the study, with all providing written
308 informed consent. Detailed inclusion and exclusion criteria are available in the **Supplementary**
309 **Materials**.

310

311 **Procedures :**

312 As illustrated in **Figure 1A**, eligible patients received SBRT (administered 5-6 times per week, 3-5 Gy
313 per session) combined with tislelizumab (200 mg on day 1) was incorporated into the treatment
314 regimen. Each three-week cycle comprised a maximum of 12 cycles of induction therapy. Patients
315 achieving complete response (CR), partial response (PR), or stable disease (SD) transitioned to
316 tislelizumab maintenance therapy (200 mg on day 1) until documented disease progression, death,
317 unacceptable toxicity, or patient withdrawal of consent. Treatment response was evaluated using CT
318 or MRI after each treatment cycle. Adverse events were systematically monitored and graded
319 according to the National Cancer Institute Common Terminology Criteria for Adverse Events (version
320 5.0).

321

322 The study enrolled 20 eligible patients on November 24, 2022 (Figure 1B). All patients received at
323 least one dose of the prescribed regimen. As of the data cutoff date (July 24, 2024), six patients
324 continued to receive maintenance therapy. The median follow-up duration was 15 months (range:
325 3.4-20.0 months, IQR: 9.6-18.2 months). Due to disease-related complications, specimens could not
326 be obtained from four patients, resulting in 16 patients being included in the per-protocol set (PPS).

327

328 **Outcomes :**

329 The primary endpoints of the study were objective response rate (ORR) and safety, encompassing
330 adverse events and serious adverse events, assessed according to RECIST version 1.1. Secondary
331 endpoints included disease control rate (DCR) and progression-free survival (PFS). ORR was
332 defined as the proportion of patients who achieved a best objective response of complete response
333 (CR) or partial response (PR) per RECIST criteria (version 1.1). DCR was defined as the proportion
334 of patients who achieved CR, PR, or stable disease (SD) according to RECIST criteria (version 1.1).
335 PFS was defined as the time from enrollment to the first documented disease progression per
336 RECIST version 1.1 or to death from any cause, whichever occurred first.

337

338 **CD8 & PD-L1 expression level :**

339 Tumoral CD8 & PD-L1 expression was measured by immunohistochemistry (IHC) (22C3 pharmDx
340 assays). The sections were scored for staining intensity according to the following scale: 0 (no
341 staining), 1 (weak staining, light yellow), 2 (moderate staining, yellowish brown), and 3 (strong
342 staining, brown), with 0 and 1 considered low expression, and 2 and 3 considered high expression.

343 The score is divided into 4 levels according to the percentage of positive cells: $0\% \leq \text{positive cell}$
344 $\text{percentage} \leq 25\%$, 1 point; $25\% < \text{positive cell percentage} \leq 50\%$, 2 points; $50\% < \text{positive cell}$
345 $\text{percentage} \leq 75\%$, 3 points; $75\% < \text{positive cell percentage} \leq 100\%$, 4 points. IHC score = cell staining
346 intensity score x positive cell percentage score. The PD-L1 combined positive score (CPS) was
347 defined as the number of PD-L1 positive cells (tumor cells, lymphocytes, macrophages) as a
348 proportion of the total number of tumor cells multiplied by 100. Positive PD-L1 expression was
349 considered when the CPS was >1 .

350

351 **Nanostring panel RNA sequencing :**

352 Due to disease-related limitations, specimens could not be obtained from four patients, resulting in a
353 cohort of 16 patients for combined analysis. Tumor tissue samples were collected both before
354 treatment (BT) and after treatment (AT). Gene expression of each sample was measured using the

355 NanoString nCounter platform (NanoString Technologies, Seattle, WA). The quantitative
356 transcriptome data were obtained based on the 289-immuno-gene panel, which includes 289 genes
357 related to the tumor, tumor microenvironment, and immune responses in cancer. The samples that
358 passed the quality control (QC), which included Imaging QC, Binding Density QC, Positive Control
359 Linearity QC, and Positive Normalization QC can be processed in further analysis. The raw count
360 data of 289 genes were normalized using the R package NanoStringNorm according to the
361 geometric mean of five housekeeping genes. The log₂ transformation was then performed on the
362 normalized data. Differentially expressed genes were identified using the "DEseq2" package,
363 employing criteria of log₂[fold change] > 1 and false discovery rate < 0.05. Heatmaps depicting the
364 expression patterns of these differentially expressed genes were generated using the
365 "ComplexHeatmap" package.

366

367 **Immune cell profile analyses and Additional immune signatures analysis**

368 The determination of immune cell types and gene sets associated with immunotherapy response
369 was informed by established literature sources (29,30). We transformed each attribute (immune
370 signature or gene set) value (GSVA score) x_i into x_i' by the equation $x_i' = \frac{x_i - x_{\min}}{x_{\max} - x_{\min}}$, where x_{\min} and x_{\max} represent the minimum and maximum of
371 the ssGSEA scores for the gene set across all samples, respectively. The detailed gene signature list
372 can be found in the **Supplementary Table**.

374

375 **Gene set enrichment and pathway analysis**

376 The Kyoto Encyclopedia of Genes and Genomes (KEGG) / Gene Ontology (GO) enrichment
377 analysis was performed using the ClusterProfiler R package. The list of gene IDs was used as the
378 input file. The Benjamini-Hochberg method was employed to adjust the p-values. The cut-off
379 threshold of p-values was set to 0.05. The enrichment results were visualized by the ggplot2 R
380 package. The enrichment statistic was set to classic.

381

382 **Statistical analyses**

383 Progression-free survival (PFS) and OS was estimated utilizing the Kaplan-Meier method. Statistical
384 analyses were conducted using R (version 3.6.1). Differences between subgroups in terms of
385 efficacy response were assessed using the nonparametric Wilcoxon rank-sum test (Mann-Whitney U
386 test), while comparisons between pre- and post-treatment samples were analyzed with the Wilcoxon
387 signed-rank test. Confidence intervals (CIs) for response rates were calculated employing the
388 Clopper-Pearson method, with all reported P values being two-sided. A P value < 0.05 was
389 considered statistically significant.

390

391 **Data availability**

392 The data generated in this study are available within the article and its **Supplementary Data**.
393 Additional data or resources related to this article are available upon reasonable request from the
394 corresponding authors.
