1 **Abstract**

2 **Introduction**

3 Handwashing facilities (HWFs) are associated with higher rates of handwashing with soap, and the
4 presence of a HWF is the global proxy indicator of household handwashing behaviour. There is limited
5 information on attributes of HWFs important to end-users with few comparative assessments of HWFs
6 from a user-perspective. We aimed to identify attributes of HWFs important to end-users and
7 determine how pre-manufactured HWFs ranked against these attributes.

8

9 **Method**

10 We identified eight pre-existing HWFs: two locally manufactured (Kalingalinga bucket and Tippy tap)
11 and six industrially produced designs (Jengu, SatoTap, SaniTap, HappyTap, SpaTap, and Kohler
12 Cleanse). Two rounds of focus group discussions were conducted with a diverse group of targeted
13 end-users in two peri-urban communities in Lusaka, Zambia. In the first, participants discussed aspects
14 of each HWF they liked and disliked, and thematic analysis was used to define nine attributes for
15 comparison across each HWF. In the second round, participants individually ranked each HWF against
16 the identified attributes, their overall preference, and overall preference once estimated retail prices
17 were revealed. Participants also ranked attributes by importance. Ranking data were modelled using
18 rank-ordered logistic regression.

19

20 **Results**

21 Discussions revealed nine attributes important to end users: appearance, water management,
22 hygienic use, convenience, water disposal, vulnerability to theft or breakage, ease of use, price and
23 maintenance. Hygienic use and water management were considered most important attributes.
24 Excluding price, facilities resembling a sink, such as the Happy Tap (34%) and Jengu (28%), had the
25 highest probability of being ranked first. With consideration for price, participants preferred lower-
26 cost HWFs such as the Kalingalinga bucket (44%), Tippy Tap (13%) and SATO Tap (10%).

27

28 **Conclusion**

29 This study identified nine attributes important to end-users that can inform future design efforts.
30 Future work will explore user preferences *in situ* by rotating households through specific HWF for an
31 extended period. Potential manufacturers should continue to iterate on HWF designs emphasizing on
32 reducing costs.

33 Introduction

34 Household access to a handwashing facility (HWF) with soap and water is crucial for achieving
35 Sustainable Development Goal (SDG) 6.2, which aims to achieve adequate and equitable sanitation
36 and hygiene for all by 2030 (United Nations 2015). The presence of an improved HWF in the home –
37 defined as the presence of both soap and water in a single location for use in handwashing – is the
38 global proxy indicator of handwashing behaviour (UNICEF, 2013). Handwashing with soap is effective
39 at reducing the risk of infectious diseases, including diarrhoea and respiratory infection (Ross et al.,
40 2023; Wolf et al., 2022). Global and regional disease outbreaks, such as COVID-19, cholera and
41 typhoid, have magnified the need for improved hand hygiene practices (Berendes et al., 2022).
42 However, global handwashing rates are low, particularly in low resource settings (Freeman et al.,
43 2014; Wolf et al., 2019).

44
45 Access to a designated HWF is associated with higher rates of handwashing with soap (Luby et al.,
46 2009; Wolf et al., 2019). Handwashing behaviour has also been attributed to physical characteristics
47 of HWFs such as tap design and container size (Devine, 2010; Ezezika et al., 2023; Hulland et al., 2013).
48 Limited access to handwashing infrastructure remains a key barrier to handwashing with soap in low-
49 resource settings (Ezezika et al., 2023). In Zambia, over 80% of the population lack access to a
50 handwashing facility with soap and water at home (WHO/UNICEF JMP 2022). To address this, several
51 HWFs have been developed and piloted specifically targeting handwashing behaviours of end-users in
52 resource limited settings (Biran, 2011; Coultas et al., 2020; Hulland et al., 2013; Husain et al., 2015;
53 Revell & Huynh, 2018; SNV 2020; Whinnery et al., 2016).

54
55 There is limited peer-reviewed literature exploring the attributes of HWFs that potential end-users
56 prioritise and few comparative assessments of multiple HWFs from a user perspective. While user
57 preferences are frequently incorporated into the design process of specific HWFs, available studies
58 focus primarily on a single improved HWF design compared to traditional facilities or focus on the
59 physical performance of the HWF (Biran, 2011; Brial et al., 2023; Devine, 2010; Hulland et al., 2013;
60 Whinnery et al., 2016). Comprehensive comparative assessments of multiple HWF designs have been
61 limited to small samples, a limited number of technologies, and use of investigator-defined
62 comparative categories (Brial et al., 2023). This two-phased study aimed to address this gap in the
63 literature by identifying the attributes of HWFs considered important by a diverse set of end-users
64 from low-income, peri-urban communities in Zambia (Phase 1) before determining how these end-
65 users rank multiple existing HWFs against these locally-defined attributes (Phase 2).

66

67 **Methods**

68 **Study Setting and Study Design**

69 The study was conducted in two peri-urban communities, George and Matero, located in the Western
70 part of Lusaka, Zambia. As the capital and largest city in Zambia, Lusaka's water and sanitation
71 infrastructure is inadequate for the current population of over two million as rapid population growth
72 has outpaced investments in these essential services (Vonk, 2021). Conditions are worse in the city's
73 unplanned and informal settlements (peri-urban areas), where 60-70% of the population reside
74 (Chiwele et al., 2022). George and Matero are located geographically next to each other and have a
75 combined population of over 320,000 residents. These communities are characterised by densely
76 packed, informal housing arrangements, where access to WASH remains a persistent challenge. Most
77 residents access water via water kiosks managed by the local council. Water supply from the
78 municipality is also largely provided through communal boreholes accessed during limited times in a
79 day at a minimal fee. Flooding coupled with poor waste management often results in cyclical cholera
80 outbreaks and other public health issues in these communities (Hubbard et al., 2020; Idoga et al.,
81 2019). Matero is considered the more affluent community, with more households accessing water
82 piped into their yard or plot. These communities were conveniently selected based on the current
83 close partnership the Centre for Infectious Disease Research in Zambia (CIDRZ) holds with the local
84 health facility in the communities.

85
86 Our study was completed in two phases – a qualitative exploratory phase used to define key attributes
87 and a second quantitative phase in which potential end users ranked facilities according to each of the
88 attributes identified. Below, we present the methods and results for each phase sequentially with a
89 combined discussion.

91 **Ethical Considerations**

92 Ethical approval was obtained from London School of Hygiene and Tropical Medicine, Research Ethics
93 Committee, London, UK (Ref: 29745) and the University of Zambia Biomedical Research Ethics
94 Committee (Ref: UNZABREC 4329-2023). All study staff were trained in Human Subject Protection
95 (HSP). Prior to study activities, an information sheet explaining the study procedure and aims was read
96 to participants. Informed written consent was obtained from all study participants in their native
97 language by written signature or thumbprint, depending on literacy status.

98 Phase 1: Attribute Determination

99 Methods

100 Handwashing facilities

101 Following a scoping exercise, a total of eight HWFs were identified for use in the study: Tippy Tap,
 102 Kalingalinga bucket, SatoTap, SpaTap, Jengu, SaniTap, HappyTap and Kohler Cleanse (Figure 1) (Jengu
 103 2024; Kohler 2024; mWater 2021; Revell & Huynh, 2018; SaniTap 2024; SNV 2020; SpaTap 2024).
 104 Selected facilities were those that were or could be manufactured locally (TippyTap, Kalingalinga
 105 Bucket) or were available from the manufacturer and could be shipped to the study site in Zambia.

Photo	Name	Approximate Retail Price	Description
	Tippy Tap	ZMW 100 or \$4	Tippy Tap is a simple, low-cost handwashing device widely promoted in resource-poor settings. It uses a container (typically a 5L jerry can) mounted on a wooden frame which is tipped using a foot-operated pedal made from a stick and string. It can be made using locally available materials.
	Kalingalinga Bucket	ZMW 250 or \$10	The Kalingalinga bucket is a locally manufactured, hand-operated HWF consisting of a 20L bucket with a tap, a small water collection basin, and a supporting frame. It is commonly used in hospitals, school, offices, homes and restaurants and is well-known in the local setting.
	SATO Tap	ZMW 100 or \$4	The SatoTap is a compact handwashing device featuring a tap mechanism that attaches to a water bottle (0.5L - 2L) and dispenses water when pressed. It is small so can be easily placed in different environments.
	SpaTap	ZMW 700 or \$28	The SpaTap features a silicone fitting that attaches to a standard plastic water bottle (0.5L - 2L). The device has a nozzle that controls water flow when squeezed or pressed. It is designed to be portable and can be hung from trees, poles or hooks using string.
	Jengu	ZMW 2000 or \$80	Jengu uses a foot pedal to pump water from a large plastic water storage container (20L) into a basin with a faucet. The basin has a drain with a hose connection so wastewater can be collected.
	SaniTap	ZMW 250 or \$10	SaniTap is a plastic packet with a nozzle that has approximately 3L of water capacity. Users can press the nozzle to control water flow. It can be suspended from a tree or pole using string.
	Happy Tap	ZMW 1000 or \$38	Happy Tap is a portable handwashing sink. It features a 18L water storage tank with a tap and a catchment tray with a drainage tube for water collection. Water flow is controlled using a lever which can be operated using the elbow. It is widely promoted in school settings.
	Kohler Cleanse	ZMW 650 or \$25	Kohler Cleanse is a hands-free faucet that attaches to the bottom of a 20L bucket. Water is dispensed when pushing up on the wrist-operated lift handle. Water can be collected using a basin underneath.

106 Figure 1 | Summary of handwashing facilities included in the study.

107 **Sampling Procedures**

108 We randomly selected one community (George) from the two communities included for this phase of
109 the study. A purposive sample of 37 individuals were selected across four participant groups: i) primary
110 caregivers of under 5 children, ii) elderly populations (> 65 years old), iii) people living with disabilities
111 and iv) adult men (age 18-64). Focus group discussions (FGDs) with 9-10 participants were held with
112 each group separately. Due to the exploratory nature of this study, the number of focus groups was
113 set to reflect anticipated diversity between key targeted groups of end-users. Community Health
114 Workers (CHWs) familiar with the communities helped to identify participants from each group.
115 Participants were approached by neighbourhood health committee members (NHCs) and invited to
116 participate.

117

118 **Data Collection**

119 FGDs were completed in October 2023 in the community health clinic. A team of four research
120 assistants facilitated the FGDs (two males, two females), all of whom held a Bachelor's degree. Two
121 research assistants were assigned per FGD (one as facilitator and one as note-taker). The team were
122 managed throughout data collection by the lead author (KK, PhD). Research assistants were fluent in
123 the local language (Nyanja) and had previous experience collecting data related to water, sanitation
124 and hygiene. Prior to data collection, research assistants completed training on FGD facilitation,
125 interview techniques, and ethical safeguarding (informed consent and data protection).

126

127 During the FGDs, participants were allocated five minutes to use each hand washing facility (HWF)
128 unguided and thereafter the facilitator showed the participants how each HWF functioned. The
129 participants were then asked to discuss each HWF as a group and reflect on which aspects of the HWFs
130 they liked the most and least. FGDs were audio recorded and detailed notes were completed by
131 research assistants. FGDs lasted around 90 minutes.

132

133 **Data Analysis**

134 Qualitative data were analysed according to the Braun and Clarke thematic analysis method (Braun &
135 Clarke, 2006). Through thematic analysis of FGD transcriptions and detailed notes, the most salient
136 attributes were identified and compared across users and across discussions of specific HWFs. This
137 generated a list of emergent attributes which were further refined and defined through discussion by
138 the study team.

139 **Results**

140 A total of 37 individuals participated across four FGDs, nine from each participant interest group
 141 except for adult men which had 10 participants. Most participants lived on a shared plot, collected
 142 water from a public tap or standpipe and did not have a handwashing facility (Table S1). Thematic
 143 analysis of FGD transcripts identified 9 key attributes that reflected various components of user
 144 preference for HWF design. These were: appearance, water management, ease of use, hygienic use,
 145 convenience, water disposal, maintenance, vulnerability and price (Table 1).

146

147 **Table 1 | Attribute determination and associated descriptions**
 148 **Table 1 | Attribute determination and associated descriptions**

Attribute	Definition	Example quote
Appearance	How the HWF looks and how it would look in the home; how appealing the design is	<p><i>“We have said that E (Happy Tap) and H (Jengu) are good for the home because they look smart because the white color and the stand are nice, the containers and pipes are also nice, and when you put it in the house it makes it look smart.” (P5-Participant with disability)</i></p> <p><i>“The color is nice, and it makes the house look smart (Happy Tap).” (P3-Participant with disability)</i></p> <p><i>“It also looks like a ‘tit’ (feeding bottle for a baby), a baby would start sucking it (Spa Tap)” (P1-Adult Men)</i></p>
Water management	Ease with which the HWF can be filled, how frequently it needs to be refilled, and how easy it is to determine how much water is available	<p><i>“There is need to increase the size of the water storage container because it cannot sustain you from morning to late afternoon (SATO Tap).” (P1-Caregiver)</i></p> <p><i>“The same issue of removing it to refill and putting it back between the ropes/string becomes extra work plus the size also, you would have to refill about seven times per day (Spa Tap).” (P3-Adult Men)</i></p> <p><i>“You cannot use it for the entire family because the water storage capacity is small. So, it can’t sustain the entire family unless a few people, one or two (SATO Tap).” (P1-Adult Men)</i></p>
Ease of use	Ease with which hands can be washed by all members of the household (adults, children, disabled)	<p><i>“Maybe height for children should be considered when making the facility which could be slightly lower (Jengu).” (P3-Elderly)</i></p> <p><i>“I have seen that there is labor on the foot not everyone can manage, holding and pressing with the foot like that (Jengu).” (P9-Participant with disability)</i></p>

		<p><i>“The other thing making it difficult to use is the opener used to open the facility unless, if it was an auto sensor where you just put your hands and water starts flowing, it becomes easy that way (Kohler).” (P5-Adult Men)</i></p>
Hygienic Use	How hygienic it is to use the facility; if the facility is dirty after use; cross contamination avoided	<p><i>“The only challenge is with the tap when opening because, you will come with dirty hands and open it to wash your hands. However, how then do you close it? Because, as you close it, you will get back the dirt on your hands (Kalingalinga).” (P6-Adult Men)</i></p> <p><i>“I also like it, it’s nice because I can wash my hands without touching the container because of the foot peddle mechanism (Tippy Tap).” (P1-Caregiver)</i></p>
Convenience	Accessibility for all members of the households; ability to place the HWF at the location needed	<p><i>“(Kalingalinga) is also simple to be put in the dining room, because it can be used anywhere. It is good because you can even put it outside.” (P6-Elderly)</i></p> <p><i>“This idea is good but not for home use unless for programs like conferences and camps because it’s easy to carry and easy to use. It is not needed for home use because its small and it has a plastic material which can get spoiled at any time (Sani Tap).” (P1-Adult Men)</i></p>
Water disposal	Ease of collecting, disposing, and/or reusing water after hand washing	<p><i>“I have seen it to be very helpful in the way we use it to wash hands because the dirty water does not go back in the container with clean water after handwashing (Jengu).” (P1-Elderly)</i></p> <p><i>“I would prefer (Jengu) because it has a good water storage capacity and drainage system which prevents children from playing with dirty water compared to B (Tippy Tap) with a small container and children can be playing with dirty water in the dish.” (P6-Adult Men)</i></p>
Maintenance	Ability to clean and maintain the facility, locate spare parts in case of breakage, cost of repairs	<p><i>“(Kalingalinga) is common because it is found in restaurants and other places. It is too common based on how much it costs. Its material is not too difficult to source, you could be passing by and have a metallic stand welded and buy a bucket to put on the stand and that will be all.” (P9-Elderly)</i></p> <p><i>“I would prefer B (Tippy Tap) because let’s say the rope gets spoiled, I can easily look for another one to replace it as long as it is strong. Conversely, if the pump for H (Jengu) gets spoiled I would fail to know where to get it.” (P4-Adult Men)</i></p>

		<p><i>“Regarding water pressure, just in case you are in the rural areas where there is water with some dirty particles, those holes are too small and they can easily be blocked and the water would stop flowing. So, it can be a difficult facility to use if the water we are using has some dirty particles (Kohler).” (P1-Adult Men)</i></p>
Vulnerability	Likelihood of theft, loss, or damage	<p><i>“Children will remove the yellow thing in front of the bottle thinking it’s a toy and they can spoil it (Spa Tap).” (P2-Caregiver)</i></p> <p><i>“The mirror is attractive, and this is not good for the public because, it can easily break or be stolen (Jengu).” (P10-Adult Men)</i></p>
Price	How expensive is the facility	<p><i>“This one is good, affordable and it is also cheap. Wherever you go, whether it’s in schools or clinics they manage to buy it. We also manage to buy it even in our homes (Kalingalinga).” (P3-Caregiver)</i></p> <p><i>“B (Tippy Tap) is good because even those that cannot afford to have the stand made can just use the ‘Y’ trees and make it.” (P4-Caregiver)</i></p> <p><i>“Yes we have said they (H -Jengu and E- Happy Tap) are nice and make the house look smart but they are expensive. We would want to have them however what are we going to use to buy them we do not have money.” (P8-Participant with disability).</i></p>

150 **Phase 2: Ranking of HWFs**

151 **Methods**

152 **Sampling Procedures**

153 A total of 8 focus group discussions (FGDs) were conducted in George and Matero with four groups of
154 participants (one in each community): i) primary caregivers of under 5 children, ii) elderly populations
155 (> 65 years old), iii) adult women (age 18-64) and iv) adult men (age 18-64). Eligibility was limited to
156 only those participants who did not participate in the first round of data collection. In addition to the
157 new participants, two additional FGDs – one with the adult men and one with the caregivers of
158 children under the age of five - that took part in Phase 1 were invited back to participate in the ranking
159 to assess if involvement in previous phases of the study impacted rankings. Focus group discussions
160 were held with each group separately. Each FGD had between eight and nine participants. Due to the
161 exploratory nature of this study, the number of focus groups was set to reflect anticipated diversity
162 between key targeted groups of end-users. Community Health Workers (CHWs) familiar with the
163 communities helped to identify participants from each group. Participants were approached by NHCs
164 in communities and invited to participate.

165

166 **Data Collection**

167 FGDs were completed between 15 January to 08 February 2024 in community health clinics. A team
168 of four research assistants facilitated the FGDs (two males, two females), all of whom held a Bachelor's
169 degree. The team were managed throughout data collection by the lead author (KK, PhD). Research
170 assistants were fluent in the local language and had previous experience collecting data related to
171 water, sanitation and hygiene. Prior to data collection, research assistants completed training on FGD
172 facilitation, interview techniques, and ethical safeguarding (informed consent and data protection).

173

174 The participants were allocated five minutes to use each facility unguided and thereafter the facilitator
175 showed the participants how each handwashing facility functioned. No information on the retail price
176 of the facilities was shared to limit the extent to which perceived affordability would limit preferences.
177 Participants were given laminated cards with images of each facility. Attributes from phase 1
178 (excluding price) were introduced one at a time and participants asked to individually rank each HWF
179 from best to worst for each attribute. (). Ties were permitted. Participants were then asked to rank
180 each HWF by their overall preference from most to least desirable. Estimated retail prices (based on
181 cost price from manufacturer or distributor as well as shipping for HWFS manufactured outside
182 Zambia) were then shared and participants were asked to again rank by overall preference. Finally,

183 participants were asked to rank each of the attributes in Phase 1 (Table 1) from most to least
184 important.

185

186 **Data Analysis**

187 Ranking data on handwashing facility preferences and attribute importance was modelled using rank-
188 ordered logistic regression by maximum likelihood using the *rologit* command in STATA 18 (StataCorp,
189 College Station, TX). Models estimate the probability that a handwashing facility would be ranked first
190 by a respondent against each attribute of interest and estimate the probability that an attribute would
191 be ranked as the most important. Rank-ordered logistic regression considers all ranks assigned to an
192 item, unlike conditional logit models, so two items with equal numbers of first place rankings can be
193 differentiated using the rank-ordered model by how many lower rankings they received. To test if
194 rankings varied between participants from different study sites (George and Matero) and participant
195 groups (adult men, adult women, elderly (65+) and caregivers), rank-ordered models with interaction
196 terms were fitted and Wald tests were performed. Variation in rankings between participants
197 returning from phase 1 versus participants new to the study was also explored. Otherwise, ranking
198 data from all participant groups were combined. Separate models were fitted to estimate predicted
199 probabilities amongst participants from different study sites and participant groups.

200

201 **Results:**

202 A total of 81 individuals participated across ten focus group discussions (Table 2). Sixty percent (49/81)
203 of participants were female and most had at least a primary education (Table S2). Participants mostly
204 lived on a shared plot and did not own a handwashing facility. Participants from Matero were more
205 likely to have received an education beyond primary-level, have formal employment and have water
206 piped into their compound.

207 **Table 2 |** Participant Numbers

FGD Number	Community	Group	No of Participants	Returning from Phase 1
1	George	Adult Men	8	No
2	George	Adult Men	8	Yes
3	George	Adult Women	9	No
4	George	Caregivers	8	No
5	George	Caregivers	8	Yes
6	George	Elderly	8	No
7	Matero	Adult Men	8	No
8	Matero	Adult Women	8	No
9	Matero	Caregivers	8	No
10	Matero	Elderly	8	No

208 **Handwashing Facility Rankings**

209 The Kalingalinga bucket had the highest probability of being ranked first across most attributes,
210 including water management (47%), ease of use (41%), maintenance (37%), water disposal (32%),
211 vulnerability (least vulnerable) (27%) and convenience (26%) (Table 3). Happy Tap and Jengu also
212 performed well, ranking highly across most attributes. Handwashing facilities which participants could
213 use without touching, such as the Happy Tap (35%), Jengu (33%) and Tippy Tap (11%), ranked highly
214 for hygienic use. Furthermore, larger facilities, such as Kalingalinga (47%), Happy Tap (22%) and Jengu
215 (15%) ranked highly for water management. Locally available handwashing facilities, such as the
216 Kalingalinga bucket (37%) and the Tippy Tap (24%), ranked highly for maintenance while handwashing
217 facilities new to the local context, such as the Happy Tap (8%) and Sanitap (6%), were considered
218 vulnerable. We observed some variation in rankings by participant group (Figure S1).

219 **Table 3 | Probability that each handwashing facility is ranked first against each attribute according to rank ordered logistic regression. Stars represent**
 220 *where p-values fell when comparing each item's log odds of being ranked higher compared to a reference item (ref).*

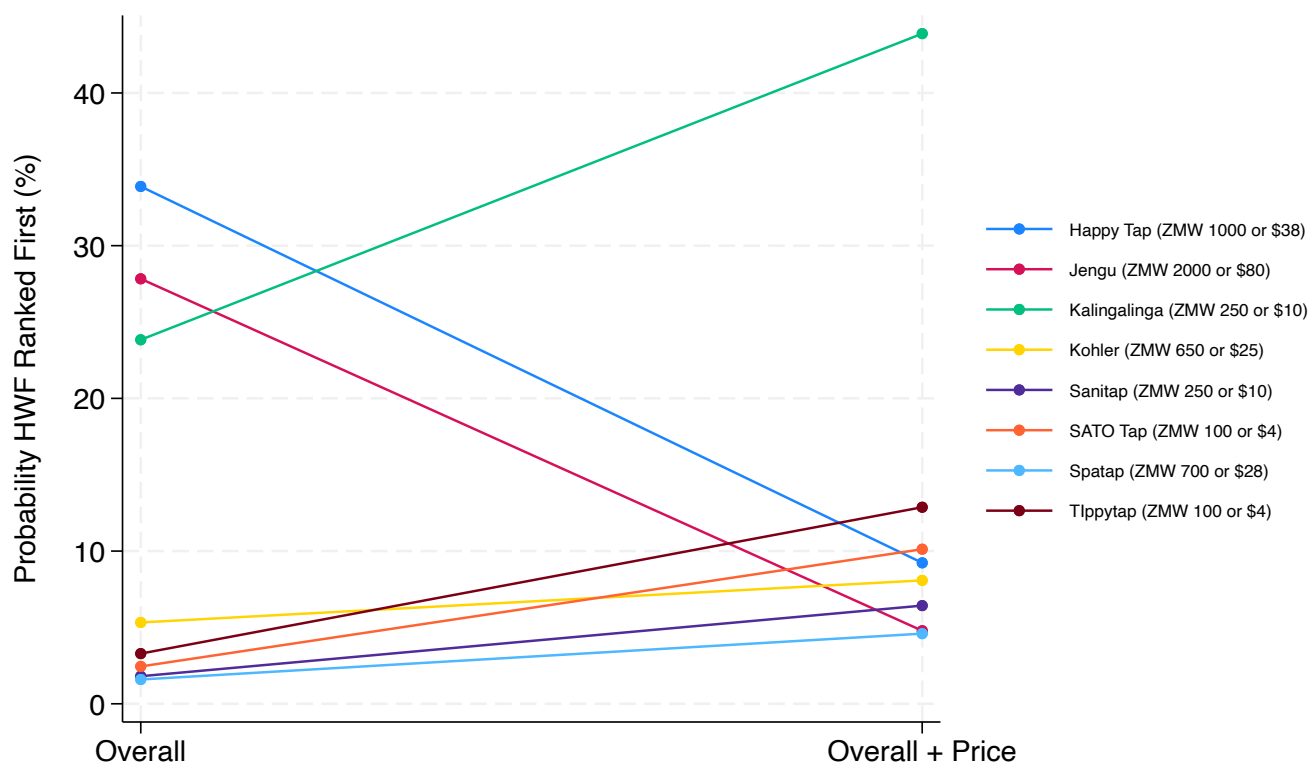

HWF	Probability HWF Ranked First (%)															
	Appearance		Water Management		Ease of Use		Hygienic Use		Convenience		Water Disposal		Maintenance		Vulnerability (least vulnerable)	
Happy Tap	50%	***	22%	***	25%	***	35%	***	15%	*	18%	***	3%	***	7%	
Jengu	19%	***	15%	***	16%	***	33%	***	8%		19%	***	5%	**	17%	***
Kalingalinga	15%	***	47%	***	41%	***	8%	***	26%	***	31%	***	37%	***	27%	***
Kohler	4%	**	9%	***	2%	*	3%		10%		14%	***	6%		16%	***
Sanitap	3%		2%	***	3%		3%		11%		5%	*	8%		6%	
Satotap	3%		1%	*	4%	*	5%	**	15%	*	4%		9%		6%

Spatap	3%	(Ref)	1%	(Ref)	3%	(Ref)	3%	(Ref)	10%	(Ref)	3%	(Ref)	8%	(Ref)	6%	(Ref)

221 *P<0.05

222 **P<0.01

223 ***P<0.001

224 Without consideration for price, the Happy Tap had the highest probability of being ranked first overall
 225 (34%) followed by Jengu (28%) and Kalingalinga (24%) (Figure 2). However, when participants were
 226 informed of the retail price of each handwashing facility, the probability of Happy Tap being ranked
 227 first decreased to 9% and the probability of Jengu being ranked first decreased to 5%. With
 228 consideration for pricing, participants were most likely to rank Kalingalinga first (44%) followed by
 229 Tippy tap (13%) and Satotap (10%) (Figure 2) (Table S3).

230 **Figure 2 | Probability of each handwashing facility being ranked first overall before and after**
 231 **consideration for price.** Retail prices provided to participants are shown in the key.

232 Wald tests found variance in overall HWF rankings between different participant groups before
 233 ($P < 0.001$) and after ($P = 0.018$) consideration for price (Figure 3). Happy Tap, Jengu and Kalingalinga
 234 ranked highly amongst all participant groups before price was considered (Figure 3A) (Table S4). Adult
 235 women and caregivers were more likely to rank Jengu first, while adult men and elderly participants
 236 were more likely to rank the Kalingalinga bucket first. With consideration for price, participants from
 237 all groups ranked Kalingalinga the highest, with limited variation in rankings for lower ranking
 238 handwashing facilities noted between participants from different groups (Figure 3B) (Table S5).
 239 Limited variation in HWF rankings was found between different study sites (Figure S2) (Table S6) (Table
 240 S7). While there was some variance in overall rankings with consideration for price between
 241 participants returning from Phase 1 vs new to the study ($P = 0.007$), the removal of participants from
 242 Phase 1 made minimal difference to the results (Table S8) (Table S9).

243 **Figure 3 | Probability of each handwashing facility being ranked first overall before (A) and after (B) consideration for price, stratified by group.**
 244 *Predicted probabilities are estimated using rank-ordered logistic regression. Wald tests found variance in overall HWF rankings before ($P < 0.001$) and after*
 245 *($P = 0.018$) consideration for price.*

246 **Attribute Rankings**

247 Hygienic use (19%) and water management (18%) were considered the most important attributes,
 248 while vulnerability (6%) was considered the least important attribute amongst all participants (Table
 249 4). Wald tests found the ranked importance of attributes varied between participant groups (P=0.02)
 250 and study sites (P<0.001), and between participants returning versus new to the study (P=0.002).
 251 Appearance was considered important amongst elderly participants (17%) and adult women (16%)
 252 but was not considered as important by adult men (9%) and caregivers (7%). Price was considered the
 253 most important attribute amongst caregivers (20%) but was not ranked highly amongst other groups.
 254 Participants from Matero were highly likely to rank price as the most important attribute (17%), while
 255 participants from George were not (5%).

256

263 Discussion

264 Presence of an improved HWF with both soap and water is associated with improved handwashing
265 behaviour at key moments (Wolf et al., 2019). We identified a range of locally and globally
266 manufactured designs with the potential to facilitate HWWS in the domestic environment, ranging
267 from simple devices that are usable with widely available plastic bottles to devices that function as a
268 kitchen sink. By comparing these multiple designs, our study has identified a core set of attributes
269 important to a diverse group of end-users that can be used to inform HWF design: ease of use, water
270 management, convenience, appearance, hygiene use, water disposal, maintenance, vulnerability and
271 price. Hygienic use and water management were considered the most important attributes, and
272 vulnerability the least important attribute. Without consideration for price, facilities which resembled
273 a sink, such as the Happy Tap and Jengu, had the highest probability of being ranked first overall. With
274 consideration for price, participants instead preferred lower-cost HWFs such as the Kalingalinga
275 bucket, Tippy Tap and SATO Tap.

276
277 Caregivers – who are usually responsible for purchasing decisions related to the domestic
278 environment in this setting – ranked price as the most important attribute. However, other groups
279 instead ranked attributes such as “hygienic use” (adult men) or “appearance” (adult women and
280 elderly) higher than caregivers. Adult men in this setting typically work in jobs where their hands get
281 dirty, which could explain their preference for a facility which is easy and hygienic to use. Price was
282 considered more important in Matero, the more affluent community. While unexpected, this could
283 be due to the inclusion of additional participants returning from Phase 1 in George, who ranked price
284 as one of the least important attributes (Table S10). Despite this, the change in HWF rankings following
285 the revelation of cost data illustrates the importance of retail price in driving end-user preferences.
286 The literature identifies cost and affordability as a key barrier to handwashing with water and soap
287 globally (Ezezika et al., 2023; Kisaakye et al., 2020). Therefore, it is crucial manufacturers consider the
288 cost of HWFs in the design process.

289
290 Our findings are consistent with a comparative assessment of seven HWFs conducted in Tanzania,
291 which found the Happy Tap was the favoured facility without consideration for price (Brial et al., 2023).
292 This study found that end-users liked the Happy Tap due to its attractive and modern characteristics,
293 aligning with the high rankings Happy Tap received for appearance in our study. Several studies found
294 end-users aspire to own facilities with a high aesthetic value, and the appearance of facilities is
295 important for use (Devine, 2010; Hulland et al., 2013; Revell & Huynh, 2018). In this study, appearance
296 was considered important by adult women and elderly participants.

297

298 Hygienic use was considered the most important attribute to participants. Hands-free handwashing
299 facility designs, such as Happy Tap, Jengu and Tippy Tap were ranked highly for hygienic use. These
300 findings align with a case study in Uganda which found end-users preferred the Tippy Tap over
301 standard jerry cans as the foot-pedal helped to avoid contamination (Biran, 2011). Foot pedal-based
302 systems have increased in popularity following the COVID-19 pandemic, in an effort to limit
303 contamination (SNV 2020). A scoping review of hand hygiene guidelines found guidelines commonly
304 recommend COVID-19-related adaptations to hand hygiene stations to limit cross contamination
305 (MacLeod et al., 2023). Therefore, HWF designs that limit cross-contamination should be prioritised.

306

307 Water management was also ranked as one of the most important attributes by end-users. HWFs with
308 a large water storage capacity, such as the Kalingalinga bucket and Happy Tap, ranked highly for water
309 management while HWFs with a small water storage capacity, such as the SATO Tap and SaniTap
310 ranked poorly. Previous studies exploring end-user preferences highlight the Happy Tap was favoured
311 due to its integrated capacity for storing water while the SpaTap was one of the least popular solutions
312 due to its small water storage capacity (Brial et al., 2023). Water storage capacity of HWFs is important
313 for acceptability and facilities requiring frequent refilling are not conducive to repeated use
314 throughout the day (Biswas et al., 2017; Devine, 2010; Ezezika et al., 2023; Hullah et al., 2013). Most
315 participants in this study do not have water piped into their dwelling. Water storage capacity was
316 ranked as particularly important amongst women and caregivers who are generally responsible for
317 water collection. With climate change expected to exacerbate the burden of water collection on
318 women's welfare, water storage capacity of handwashing facilities will remain an important attribute
319 of HWF designs to end-users (Carr et al., 2024).

320

321 We acknowledge the limitations of this study. First, participants were only given a limited amount of
322 time to use each of the HWFs in controlled settings before being asked to rank them. Therefore, this
323 study does not consider how participants would rank the HWFs after using them for a longer period
324 in a household setting. This limitation will be addressed in a subsequent Trial of Improved Practices
325 (TIPS) with top-ranking handwashing facilities. Secondly, a Hausman test revealed the same decision
326 weights were not applied with higher and lower ranking HWFs, with rank-ordering of lower ranking
327 HWFs more random than higher ranking HWFs (Hausman & Ruud, 1987). Therefore, the regression
328 model's ability to predict HWF rankings is less predictable for lower-ranked items. Thirdly, it is possible
329 that comments from other participants could have biased participant rankings through social
330 desirability mechanisms. However, this was mitigated by conducting rankings individually. Fourthly,

331 purposive sampling techniques used in this study mean results may not be generalisable beyond
332 populations with similar characteristics to those included in our study. Finally, it is important to note
333 the results of this study may not be applicable to different settings, such as emergencies, where
334 different attributes of HWFs are likely to be prioritised (Husain et al., 2015).

335

336 **Conclusion**

337 This study identified a set of HWF attributes that were important to a diverse set of end-users which
338 can be used to inform future design efforts. Hygienic use and water management were considered
339 the most important attributes, and vulnerability the least important attribute. In the absence of cost
340 data, HWFs that resembled a traditional sink, such as the Happy Tap and Jengu, were the highest
341 ranking HWFs. Price further informed user preferences, with participants instead preferring lower cost
342 HWFs such as the Kalingalinga bucket, Tippy Tap and SATO Tap. Potential manufacturers should
343 continue to iterate on HWF design with an emphasis on reducing costs. Future work will explore user
344 preferences in situ by rotating households through specific HWFs for an extended period.
