ABSTRACT

Objective

This study investigates the relationship between screen time, screen content, and the risk of Attention Deficit Hyperactivity Disorder (ADHD) using data from a large sample. Specifically, it examines how different types of screen content (such as educational videos, cartoon videos, and interactive videos) are associated with the risk of ADHD. The aim is to offer a scientific foundation for the rational management of children's screen time and screen content.

Methods

We collected data through a questionnaire survey involving a study population of 41,494 children from Longhua District, Shenzhen City, China. The questionnaire

NOTE: This preprint reports new research that has not been certified by peer review and should not be used to guide clinical practice. recorded the daily screen time and the type of content viewed by the children at ages

1-3 years and assessed their risk of ADHD using the Strengths and Difficulties Questionnaire (SDQ) at ages 4-6 years. Hierarchical logistic regression analysis, controlling for confounding factors, was employed to explore the associations between screen time, screen content, and ADHD risk.

Results

In the total sample, 6.7% of the participants had screen time exceeding 60 minutes per day, with educational videos predominant type (63.4%). 16.5% of the participants were identified as being at risk for ADHD. Statistically significant positive associations with ADHD were observed across all categories of screen time ($P < 0.001$). Moreover, as screen time increased, the risk of ADHD also rose ($OR_{1-60 \text{ mins/d}} = 1.627$, $95\%CI = 1.460 \sim 1.813$; $OR_{61-120 \text{ mins/d}} = 2.838$, $95\%CI = 2.469 \sim 3.261$; $OR_{>120 \text{ mins/d}} = 3.687$, $95\%CI = 2.835 \sim 4.796$).

Significant positive associations with ADHD were observed across all categories of screen time in the educational videos and cartoon videos. For the educational videos group, the odds ratios were as follows: $OR_{1-60 \text{ mins/day}} = 1.683$ ($95\% CI = 1.481 \sim 1.913$), $OR_{61-120 \text{ mins/day}} = 3.193$ ($95\% CI = 2.658 \sim 3.835$), and $OR_{>120 \text{ mins/day}} = 3.070$ ($95\% CI = 2.017 \sim 4.673$). For the cartoon videos group, the odds ratios were: $OR_{1-60 \text{ mins/day}} = 1.603$ ($95\% CI = 1.290 \sim 1.991$), $OR_{61-120 \text{ mins/day}} = 2.758$ ($95\% CI = 2.156 \sim 3.529$), and $OR_{>120 \text{ mins/day}} = 4.097$ ($95\% CI = 2.760 \sim 6.081$).

However, no significant associations with ADHD risk were found for any category of screen time in the interactive videos group ($OR_{1-60 \text{ mins/d}} = 0.744$, $95\%CI = 0.361 \sim 1.534$; $OR_{61-120 \text{ mins/d}} = 0.680$, $95\%CI = 0.296 \sim 1.560$; $OR_{>120 \text{ mins/d}} = 1.678$, $95\%CI = 0.593 \sim 4.748$).

Conclusion

As screen time increases, the risk of ADHD also rises. Both educational videos and cartoon videos show a positive correlation between screen time and ADHD risk. However, no significant association was found between screen time and ADHD risk when it came to interactive videos. This study underscores the importance of reasonably managing children's screen time, particularly the time spent watching educational and cartoon videos.

Introduction

In recent years, the widespread adoption of electronic devices has significantly increased children's screen time, raising widespread societal concern about the impact of electronic screens on children's mental health[1, 2]. Most existing research focuses on the association between screen time and the risk of ADHD, highlighting its potential impact on children's mental health development[3, 4]. However, these studies often overlook the fact that different types of screen content may have distinct effects on children's mental health[5].

ADHD, a common neurodevelopmental disorder, is characterized by core symptoms such as inattention, hyperactivity, and impulsivity, which pose challenges to children's learning, social interaction, and emotional regulation abilities[6, 7]. Although the exact pathophysiology of ADHD is not fully understood, environmental factors-including lifestyle factors-are recognized as playing a significant role in its development[8]. Among these factors, the relationship between screen time and ADHD risk has been a hot topic of research in recent years. However, studies specifically investigating the association between different type of screen content and ADHD risk remain scarce.

Existing studies on the link between screen time and hyperactive behavior generally indicate that excessive screen time may indirectly increase the risk of ADHD by affecting children's sleep, physical activity, and social interaction[9, 10]. However, these studies often fail to explore the differential impacts of various types of screen contents on children's mental health in depth[11, 12]. Educational and cartoon videos, despite their perceived educational value, are primarily one-way information inputs that lack interaction. Their rapidly changing visuals and intense sensory stimulation may adversely affect children's ability to concentrate and self-regulate[13]. In contrast, interactive videos may more effectively promote children's social interaction and

cognitive development, though their specific impact on ADHD risk requires further investigation.

This study leverages the extensive data resources from the Longhua Child Cohort Study (LCCS) in Shenzhen to comprehensively assess the relationship between children's screen time, different types of screen content, and the risk of ADHD. The aim is to provide scientific evidence to guide parents and educators in reasonably managing children's screen time and optimizing screen content selection, thereby effectively reducing the risk of ADHD in children.

Methods

Study design and participants

This study was conducted in accordance with the Declaration of Helsinki. The data for this project were sourced from the 2021 survey of the LCCS. The LCCS was a large-scale epidemiological survey conducted in Longhua District, Shenzhen, China, aiming to assess the impact of children's lifestyle habits on early psychological and behavioral development of preschoolers.

The research project was conducted across 250 kindergartens in the Longhua District of Shenzhen in 2021. From 8th October to 23th November 2021, the project was publicized to the parents of kindergarten children, encouraging their participation. After obtaining parental consent, informed consent forms were signed by the parents, and a questionnaire survey was conducted. A total of 59,600 questionnaires were distributed, and 56,740 were returned, yielding a response rate of 95.2%. After excluding 15,246 questionnaires with incomplete information, the final sample size was 41,494. This study was approved by the Ethics Committee of Longhua Maternal and Child Health Hospital (Ethics approval No. 2016102501).

Data collection

The questionnaire collected information on family demographic characteristics, daily screen time, and the types of programs viewed during screen time by children when they were at the age of 1-3 years old. Additionally, it assessed the risk of ADHD using the Strengths and Difficulties Questionnaire (SDQ) for them at the age of 4-7

years old. All participants had signed the Human Ethics and Consent to Participate forms and agreed to be involved in this study.

Measurement of screen time (major exposure variables) and category of

"Screen time" was defined as time spent looking at screens such as phones, TVs, tablets or desktop computers, game consoles, as reported by the children's parents. We chose to collect information on screen time for children aged 4 to 7. An ordinal categorical survey was conducted to assess screen time, and a nominal categorical survey was conducted to evaluate the types of programs viewed during screen time (Table 1).

Table 1 Questions and options regarding the screen time and program of the screen time.

No.	Questions	Options
Q1	How long was the screen time of your child/children at his/her/their age of 1-3 years old per day?	0 mins/d 1~60 mins/d 61~120 mins/d >120 mins/d
Q2	What types of programs did your child/children primarily view during screen time at his/her/their age of 1-3 years old?	Educational videos Cartoon videos Interactive videos

*Educational videos : (with explicit prosocial or cognitive components [eg, Sesame Street and QiaoHu, a similar program in China])

*Cartoon videos : (eg, Thomas & Friends and Super Flying Man)

*Interactive videos (social media or interactive game)

Measurement of ADHD risk

In this study, the Strengths and Difficulties Questionnaire (SDQ) was used to assess the risk of ADHD in children. The SDQ, developed by American psychologist Goodman in 1997, is a concise behavioral screening scale[14]. In 2005, China established norms for the Chinese population[15]. The scale consists of 25 items, covering 5 dimensions: emotional symptoms, conduct problems, ADHD symptoms, peer problems, and prosocial behavior. Items on the SDQ are rated on a scale from 0 to 2, with 0 indicating no agreement, 1 indicating partial agreement, and 2 indicating perfect agreement. The total score for ADHD symptoms ranges from 0 to 5 for normal, 6 for borderline, and 7 to 10 for abnormal. Based on these scores, participants can be categorized into a normal group (≤ 5) and an ADHD risk group (≥ 6). The scale

demonstrated good reliability, with a Cronbach's α coefficient of 0.749[16, 17].

Covariates

The following confounding covariates were included in the analysis: child's gender, age, parental marital status, parents' educational attainment, household monthly income, single-child status, and whether the content of screen time programs was discussed with the child.

Statistical analysis

Descriptive statistics were used to characterize the study population. Mean \pm standard deviation (SD) and sample number (percentage) were presented for continuous and categorical variables, respectively. A chi-square test was used to compare differences in screen time, types of programs viewed during screen time, and covariate variables among ADHD risk groups. Logistic regression analysis was employed to explore the association between screen time and ADHD risk.

Results

Participants sociodemographic characteristics and differences in screen time, types of programs viewed during screen time, and covariate variables among ADHD risk groups

Participants' SDQ scores and associated ADHD risk levels are presented in Table 1. In the total sample, we found that 7.5% of the participants exhibited abnormal levels of ADHD symptoms (defined as a score of 7-10). Additionally, 9.0% of the participants were on the borderline for ADHD symptoms (defined as a score of 6). Overall, 16.5% of the participants were at risk for ADHD.

Table 2 ADHD scores and risk of the Strengths and Difficulties Questionnaire (SDQ)

Category	ADHD scores (Mean \pm SD)	ADHD risk (%)
Total	3.69 \pm 1.93	41494 (100.0)
Normal	3.09 \pm 1.45	34645 (83.5)
Edge value	6.00 \pm 0.00	3737 (9.0)
Abnormal	7.60 \pm 0.84	3112 (7.5)

Participants' demographics and characteristics are summarized in Table 3. A total of 41,494 children (22,113 boys [53.3%] and 19,381 girls [46.7%]; mean [SD] age, 5.13 ±0.67 years old) completed the questionnaire. The risk of ADHD was higher in boys compared to girls(18.9% vs. 13.7%, $\chi^2=201.855$, $P<0.001$).

Relationship between screen time and ADHD risk

We performed a logistic regression analysis to investigate the associations between screen time and ADHD risk (Table 4). Statistically significant positive associations with ADHD were observed across all categories of screen time ($\beta_{1\sim60 \text{ mins/d}} = 0.487$, $\beta_{61\sim120 \text{ mins/d}} = 1.043$, $\beta_{>120 \text{ mins/d}} = 1.305$, $P<0.001$). Additionally, as screen time increased, the risk of ADHD also rose ($OR_{1\sim60 \text{ mins/d}}=1.627$, $95\%CI=1.460\sim1.813$; $OR_{61\sim120 \text{ mins/d}}=2.838$, $95\%CI=2.469\sim3.261$; $OR_{>120 \text{ mins/d}}=3.687$, $95\%CI=2.835\sim4.796$).

Table 4 Relationship between screen time and ADHD risk (N=41,494)

Screen time	β	OR (95%CI)	P
0 mins/d		Ref.	
1~60 mins/d	0.487	1.627 (1.460~1.813)	<0.001
61~120 mins/d	1.043	2.838 (2.469~3.261)	<0.001
>120 mins/d	1.305	3.687 (2.835~4.796)	<0.001

Screen time was transferred into dummy variables. Abbreviation: β , coefficient of Logistic Regression Analysis with adjustment for age, gender, parental marital status, maternal and paternal education attainment, household monthly income, single child status, types of programs viewed during screen time and discuss the content of screen time program with the child. OR, odds ratio of Logistic Regression Analysis. 95%CI, 95% confidence interval of OR of Logistic Regression Analysis. Bold font indicates statistical significance.

Relationship between screen time and ADHD risk in different types of programs viewed during screen time

We conducted a stratified logistic regression analysis to further investigate the associations between screen time and ADHD risk across different types of programs viewed during screen time (Table 5). Statistically significant positive associations with ADHD were observed across all categories of screen time in the educational videos and cartoon videos groups. (education videos group [$OR_{1\sim60 \text{ mins/d}}=1.683$, $95\%CI=1.481\sim1.913$; $OR_{61\sim120 \text{ mins/d}}=3.193$, $95\%CI=2.658\sim3.835$; $OR_{>120 \text{ mins/d}}=3.070$,

95%CI=2.017~4.673]; Cartoon group [$OR_{1\sim60 \text{ mins/d}}=1.603$, 95%CI=1.290~1.991; $OR_{61\sim120 \text{ mins/d}}=2.758$, 95%CI=2.156~3.529; $OR_{>120 \text{ mins/d}}=4.097$, 95%CI=2.760~6.081])

However, no category of screen time was significantly associated with ADHD risk in the social software group ($OR_{1\sim60 \text{ mins/d}}=0.744$, 95%CI=0.361~1.534; $OR_{61\sim120 \text{ mins/d}}=0.680$, 95%CI=0.296~1.560; $OR_{>120 \text{ mins/d}}=1.678$, 95%CI=0.593~4.748).

Table 5 Relationship between screen time and ADHD risk in different types of programs viewed during screen time (N=41,494)

Type of content viewed during screen time	Educational videos (n=26320)	Cartoon videos (n=14516)	Interactive videos (n=658)
0 mins/d		Ref.	
1~60 mins/d	1.683 (1.481~1.913)	1.603 (1.290~1.991)	0.744 (0.361~1.534)
61~120 mins/d	3.193 (2.658~3.835)	2.758 (2.156~3.529)	0.680 (0.296~1.560)
>120 mins/d	3.070 (2.017~4.673)	4.097 (2.760~6.081)	1.678 (0.593~4.748)

Screen time was transferred into dummy variables. Abbreviation: *OR* (95%CI), odds ratio (95% confidence interval of *OR*) of Logistic Regression Analysis with adjustment for age, gender, parental marital status, maternal and paternal education attainment, household monthly income, single child status and discuss the content of screen time program with the child. Bold font indicates statistical significance.

Discussion

The Relationship between Screen Time and ADHD Risk

In this study, we observed a significant positive correlation between screen time and the risk of ADHD among children. This association may be attributed to the combined effects of multiple mechanisms. Firstly, the use of screen devices, especially before bedtime, may disrupt children's sleep patterns by inhibiting the secretion of melatonin, thereby affecting their attention and emotional regulation abilities[18-20]. Secondly, the fast-paced and highly stimulating content on screens may overstimulate children's attention systems, impacting their cognitive and attentional development[21, 22]. Additionally, increased screen time often comes at the expense of physical activity, which has a beneficial effect on improving children's attention and reducing hyperactive behaviors[23, 24]. Furthermore, excessive screen time may reduce children's social interactions with peers, and a lack of social skills is associated with

the development of ADHD, leading to peer relationship problems and difficulties in school adjustment[25-27]. These findings underscore the importance of reducing children's screen time to preventing ADHD.

The Relationship between Screen content and ADHD Risk

Educational videos, as a medium for children to acquire knowledge, do not universally exert positive influences[28-30]. Previous research findings on educational videos have been inconsistent. Some studies suggest that educational videos do not significantly increase the risk of attention deficit hyperactivity disorder (ADHD)[31], while others have found that prolonged exposure to educational videos may adversely affect children's attentional systems [32]. This study reveals that as the time spent watching educational videos increases, the risk of ADHD among children rises significantly. This may be attributed to the fact that educational videos often contain a wealth of information with rapid scene changes, which can easily overstimulate children's attentional systems, thereby impairing their self-regulation abilities[33, 34]. Additionally, the lack of interactivity in educational videos may deprive children of opportunities to practice and apply knowledge in real-life situations, impacting their social skills and problem-solving abilities[35, 36].

Cartoon videos, with their vibrant colors and exaggerated movements, are popular among children, but prolonged viewing may also elevate the risk of ADHD. The fast-paced and highly stimulating content in cartoon videos may excessively activate children's attentional systems[37], leading to decreased attention to the real world and affecting cognitive and emotional development [38]. Moreover, violent or stimulating content in cartoon videos may adversely affect children's mental health[39, 40], further increasing the risk of ADHD.

This study finds that, unlike educational and cartoon videos, interactive videos do not show a significant association with the risk of ADHD. Biofeedback therapy, used in attention training for children with ADHD[41], leverages interactive videos to train children's attention. During these sessions, children must adjust their brain electrical activity in real-time while watching interactive videos, thereby enhancing their

attention [42, 43]. Interactive videos provide children with a greater sense of participation and feedback opportunities[44, 45], which may contribute to the lack of significant association between interactive videos and ADHD risk. However, this does not imply that children should increase their use of interactive videos indiscriminately.

This study possesses notable strengths, primarily reflected in its large sample size (41,494 children) and meticulous data analysis, allowing for an in-depth investigation into the relationship between screen time and ADHD risk, as well as the specific impacts of various screen contents (educational videos, cartoon videos, and interactive videos). However, this study also has several limitations. Firstly, the cross-sectional design precludes direct inference of causality, necessitating future research to adopt a longitudinal design for further validation of the findings. Secondly, the data relies on parental recall, which may be subject to recall bias. Lastly, despite controlling for multiple confounding factors, there may still be other unrecognized factors influencing the results.

Conclusion

As screen time increases, so does the risk of ADHD. For both educational and cartoon videos, screen time is positively correlated with ADHD risk. However, no significant association between screen time and ADHD risk was found when using interactive videos. This study underscores the importance of reasonably controlling children's screen time, particularly the time spent watching educational videos and cartoon videos.
