Abstract

Chemotherapy-associated cachexia results in significant metabolic disturbances and loss of skeletal muscle. These physiologic effects increase fatigue, reduce physical functioning, and decrease quality of life in patients undergoing treatment for cancer. Mitochondrial dysfunction, a hallmark of metabolic disturbances in the skeletal muscle, has previously been studied in health participants using invasive muscle biopsy and/or time consuming, high-cost magnetic resonance spectroscopy. However, less is understood regarding mitochondrial dysfunction in patients with cancer. Near infrared spectroscopy (NIRS) is a non-invasive and cost-effective approach to assessing mitochondrial function of skeletal muscle by measuring oxygenated and deoxygenated hemoglobin and calculating the resulting tissue saturation index. NIRS has not yet been utilized to evaluate skeletal muscle change in cancer patients throughout chemotherapy. Therefore, we plan to conduct a single center clinical trial, using an observational mixed model repeated measures design to evaluate the change in mitochondrial oxidative capacity from baseline and throughout progression of an oncologist-prescribed chemotherapy regimen. Evaluation of mitochondrial function will be performed by taking real-time, NIRS in-situ measurements within the working muscle during stationary cycling exercise and subsequent recovery periods (e.g. “on” kinetics and “off” kinetics). We also plan to observe if there is a difference in mitochondrial oxidative capacity between different chemotherapy regimens across different patients. This pilot

study will provide information on the feasibility of capturing on/off kinetics mitochondrial function data longitudinally using NIRS in patients newly diagnosed with breast or gynecological cancer, provide preliminary data for future extramural funding, as well as inform the scientific community of results through dissemination via conferences and peer-reviewed publications.

69

70 **Introduction**

71 In the United States, more than 3.8 million women are currently receiving chemotherapy
72 treatment, or have completed treatment, for breast or gynecological cancer [1]. Fortunately, over
73 the past 25 years, the ability to detect and treat cancer has allowed breast cancer 5-year survivor
74 rates to increase to 85 [1], ovarian cancer 5-year survivor rates to increase to 49% [2], and
75 uterine cancer 5-year survivor rates to increase to 81% [3]. Unfortunately, while chemotherapy
76 has improved survival rates amongst patients with breast and gynecological cancer, side effects
77 include unfavorable body composition changes [4], increases in fatigue [5], reductions in
78 physical functioning [6], and decreased quality of life (QOL) [7]. Most of these symptoms are
79 due to chemotherapy-induced muscle wasting, also known as cachexia [8–10]. According to the
80 National Cancer Institute, cachexia is estimated to occur in up to 80% of people with advanced
81 cancer [8,11] and involves reduced size and content of mitochondria [12,13] and subsequent
82 deterioration of mitochondrial function and its oxidative capacity associated with reduced energy
83 production for physical functioning [9,10,14]. Cachexia has negative implications for patients
84 with breast and gynecologic cancer; therefore, the increase in survivorship has been an increase
85 in focus on understanding mechanisms of cachexia, such as mitochondrial dysfunction, with the
86 aim of studying these mechanisms to understand how to improve quality of life for [10].

87 Previous studies have relied on more invasive tools to assess pathological progression of
88 mitochondrial [15,16]. Muscle biopsies have been the gold standard assessment but cause

significant discomfort to the patient and may not represent *in vivo* activation of the skeletal working muscle tissue associated with [17]. Magnetic Resonance Spectroscopy (MRS) provides *in vivo* measurements but is cost prohibitive, time intensive, requires technical expertise, and competes with other clinical needs within the [17]. Metabolic ventilatory measures have been established as a gold standard in evaluation of pathophysiology with many chronic diseases except for large scale studies in cancer chemotherapy treatment [18–20]. These measurements could provide critical mechanistic understanding of oxygen delivery and utilization from a systematic whole-body approach [21]. To understand local skeletal muscle oxygen uptake kinetics, Near Infrared Spectroscopy (NIRS) has been validated with muscle biopsies and [22,23], as a low cost, non-invasive alternative assessing mitochondrial capacity in clinical [17]. NIRS measurement of tissue oxygenation has been well studied and a thorough background on NIRS can be found elsewhere [17,22,24,25]. Briefly, biological tissue has a relatively good transparency for light in the near infrared region (700-1300 nm) and transmits photons through organs for *in situ* monitoring. The refracted light is converted into grams of oxyhemoglobin (O₂Hb) and deoxyhemoglobin (HHb) based on the modified Beer-Lambert law[26]. NIRS devices with multiple transmitters at different distances from the receiver can calculate the Tissue Saturation Index (TSI)=O₂Hb/(O₂Hb + HHb) and reflects the percentage of measured blood that is oxygenated.

Assessment of mitochondrial capacity with NIRS includes studies of clinical populations with peripheral artery [27], chronic kidney [24], and neurologic diseases such as traumatic spinal cord injury and multiple [22], as well as comparisons with healthy [28] and assessment of age-related differences in skeletal muscle oxidative [17]. However, there is a dearth of NIRS studies

examining the effects of chemotherapy on skeletal muscle mitochondrial function in patients with cancer. Only two studies to our knowledge have utilized NIRS to measure muscle oxygenation variables in cancer survivors. Ederer, et al. [29] determined that [HHb] and [Hb]total were significantly lower in eight cancer survivors (all eight received chemotherapy and five received radiation) compared to healthy controls during exercise at ventilatory threshold. Grigoriadis, et al., [30] did not find a significant difference in muscle oxygenation variables between 23 patients with breast cancer (16 received chemotherapy, nineteen received radiation therapy, and 21 received hormonal therapy) and 23 participants who served as age and BMI matched controls. Recent literature of near infrared spectroscopy related to cancer primarily involves detection and identification of cancerous [31] or the use of near infrared light as a photoimmunotherapy [32]. Therefore, the hypothesized loss of mitochondrial capacity throughout chemotherapy treatment has not been studied longitudinally starting at baseline and tracking through the chemotherapy regimen in breast and gynecologic cancer patients with NIRS to date.

The aims of our study are to develop a protocol that 1) assesses mitochondrial dysfunction in cancer patients using exercise that is tolerable for the patients throughout the entire chemotherapy regimen and 2) explores the link between oxygen utilization at the muscular level via NIRS with whole body traditional metabolic ventilatory measures. This protocol will help us to observe the changes in mitochondrial functional capacity throughout an entire chemotherapy regimen for each patient and between different chemotherapy regimens over time. The protocol also will help us evaluate a potential correlation between subjective self-reported fatigue and perceived effort with corresponding objective metabolic and NIRS

measurements. The proposed study will help inform clinical decision makers in the oncology community regarding current chemotherapy regimens (based upon the National Comprehensive Cancer Network, NCCN) that patients may best tolerate for cachexia and fatigue.

Materials and Methods

Organization and conduct

The study protocol (Fig 1) was approved in July of 2021 by the Prisma Health Office of Human Subjects Protection Institutional Review Board Committee C (Protocol # Pro00110826). This study is sponsored through the Prisma Health Cancer Institute Office of Philanthropy and Partnership, the University of South Carolina School of Medicine Greenville Summer Scholars Program, and Furman University. The study sponsors and funders, played no role in study design; collection, management, analysis, and interpretation of data; writing of the report; and the decision to submit the report for publication, including whether they will have ultimate authority over any of these activities. This clinical trial has been registered with clinicaltrials.gov (Identifier: NCT006672497). Data collection started on July 26, 2021 and is ongoing through May 1, 2025.

(Insert Figure 1 here)

Fig 1. Schedule of Enrollments, Interventions, and Assessments.

Experimental Design

We will use an observational mixed model repeated measures design to longitudinally compare (pre-chemotherapy and throughout treatment) patients' skeletal muscle mitochondrial capacity of the vastus lateralis during stationary cycling. The study population will include female patients with breast or gynecological cancer. All testing will take place in the University of South Carolina School of Medicine Greenville's Human Performance Laboratory in the Prisma Health Cancer Institute.

Sample Size

We conducted a power analysis using Monte Carlo data simulation. We conducted the analysis using a mixed effects model with a fixed effect of chemotherapy cycle (time) and random effects for slope and intercept by participants with unstructured correlation [33–36]. Due to limited studies of NIRS measurements of patients with cancer, we used the conservative estimate of average recovery kinetics time constant (τ) of patients with chronic heart failure (25.35 seconds) and extrapolate average change in τ throughout chemotherapy from Foulkes using results from Beever [37,38]. We assume that the random intercept will follow a gamma distribution with shape 1.57, a scale of 12.5, and a right shift of 13.25. Additional assumptions from Foulkes [38] and Beever [37] include the random slope is assumed to follow a normal distribution with an extrapolated standard deviation, as well as a normal distribution of the error

with standard deviation of 5.54 [39,40]. Analysis indicates that using a linear mixed effects model with sample size of at least $n=30$ will be able to detect an effect of chemotherapy on τ with a power of 0.8. As the effect of chemotherapy type on τ is unknown and unable to be approximated with data simulation, we are unable to conduct a full power analysis with the effect of chemotherapy type on τ [29,41,42]. We assume that at least $n=8$ of each chemotherapy type will be necessary to detect any differences in trajectory of τ over time.

Participants and Eligibility Requirements

Participants recruited for this study will be female patients with breast cancer or gynecological cancer who will undergo a standard of care chemotherapy treatment as directed by their oncologist. Participants who are cleared by their oncologist to participate will be recruited through informative pamphlets and by oncology nurses trained in research and human subjects protection in Prisma Health System's Cancer Institute at Greenville Memorial Hospital, as well as Prisma Health affiliated oncologists' offices. Participants will be informed of the study's purpose, availability, timeline, and potentially associated minimal risks. Study staff will then obtain written informed consent from participants who agree to participate and before any data collection.

Table1. Inclusion and Exclusion Criteria

Inclusion Criteria
Female patients diagnosed with breast cancer or gynecological cancer without distant metastasis
Age > 20 years old
Able to perform exercise on a stationary cycle ergometer at moderate intensities for a maximum of 15 minutes
Hemoglobin (Hb) values > 10 g/dl at baseline
Alanine aminotransferase (ALT) and Aspartate transferase (AST) values less than 2.5X the upper limit of normal by institutional standards
Godin-Shephard Leisure Time Physical Activity Questionnaire (GLTEQ) score of 14 or higher
Exclusion Criteria
Metastatic breast or gynecological cancer

Clinically advanced cardiovascular disease or pulmonary disease or disease requiring continuous oxygen supplementation
Greater than 2 centimeters of subcutaneous adipose tissue on the anterior thigh
Inability to walk or stand, movement disorders, spinal cord injuries
Autoimmune disorders
Pregnant or breastfeeding
Mini-Mental State Examination (MMSE) score < 24
History of chemotherapy within 5 years prior to beginning participation

189

190 **Observational Protocol for First and Subsequent Visits**

191 Before starting chemotherapy, patients will undergo baseline testing that includes a
 192 lactate threshold test and an ON-OFF kinetics exercise test. The lactate threshold test will
 193 determine the power output (110% power at lactate threshold, P_{LT+}) to be used for the follow-up
 194 baseline on-off kinetics test (ON-OFF). The ON-OFF kinetics test will take place at least 24
 195 hours after the lactate threshold test and consist of 3 cycles of 2 minutes at P_{LT+} and 2 minutes of

complete rest. Whole body O₂ uptake and CO₂ production will be captured via a metabolic cart during each test. Testing will take no more than 60 minutes per session, with a maximum study total of 300 minutes (about 5 hours) of participation per patient. Patients will be requested to avoid exercise and use of certain substances (tobacco, alcohol, caffeine, and contraindicated medications) 24 hours before testing. If laboratory baseline evaluation cannot be completed prior to the participant's treatment initiation, treatment will not be delayed, and patients will be waived from the study.

The independent variables in this study are drug regimen and number of chemotherapy treatments. The dependent variables in this study will be the changes in O₂Hb, HHb, and TSI of the vastus lateralis, indicative of mitochondrial oxidative capacity after a bout of cycling. The specific variables measured will be the average recovery kinetics time constant, τ , and TSI. Indirect calorimetry (O₂ uptake, CO₂ production) also will be captured at rest and during the ON/OFF kinetics as control variable comparisons for whole-body O₂ uptake and utilization.

Instruments and Equipment

The following devices will be utilized throughout the study: NIRS PortaMon by Artinis (Einsteinweg, Netherlands), Lode Corival (Groningen, Netherlands) stationary bike ergometer, Parvo Medics TrueOne 2400 (Salt Lake City, Utah) metabolic cart, Polar FT7 heart rate (HR) monitor (Kempele, Finland), Lactate Plus analyzer (Edina, Minnesota) and Sonosite Titan Portable Ultrasound System (Bloomfield, Connecticut) for adipose tissue thickness measurement.

216 **Fatigue and Quality of Life Surveys**

217 We will administer the Mini-Mental State Exam (MMSE) [43–45], Brief Fatigue
218 Inventory (BFI) [46], Physical Activity Intake [47,48], PROMIS Global Health [49,50], and
219 GLTPAQ surveys [51] prior to participant engagement in cycling exercises at the beginning of
220 the first visit. We will administer BFI, PROMIS Global Health, and Physical Activity follow-up
221 surveys at the beginning of each individual study session to assess any changes in cancer related
222 fatigue associated with chemotherapy treatment that may develop throughout the study period.

223

224 **Visit #1: Lactate Threshold Test to Determine Power Output, NIRS**

225 **Orientation**

226 Participants will be asked to wear comfortable exercise clothes with shorts or equivalent
227 so that the NIRS device can be placed directly on the skin. Participants will enter the
228 performance lab and sit at rest in a chair. The NIRS device will be secured to the participant's
229 leg at a standardized measurement of $\frac{2}{3}$ distance from the anterior superior iliac spine to the
230 lateral border of the patella [52]. This distance will be measured and marked medially and
231 laterally on the patient's leg at a place that will not disrupt signal transmission. At this marked
232 location, an ultrasound probe will be used to measure the subcutaneous adipose tissue thickness
233 (ATT) between the epidermal layer and the muscular layer. If the ATT meets the
234 inclusion/exclusion criteria, the NIRS device will be placed on the vastus lateralis. The
235 ultrasound ATT measurement will be recorded. The NIRS device will be secured to the

participant's leg via double-sided non-latex adhesive tape applied between the device and the leg and lightly secured in position to the skin via non-latex tape. Pictures of the anatomical location of NIRS device placement with a tape measure from the center of the anterior border of the patella to the top of the NIRS device will be taken to standardize placement at every visit.

The patient will then complete the following questionnaires: contact information form, GLTPAQ, MMSE, BFI, PROMIS, and Physical Activity Form. After the completion of the questionnaires, study staff will review the GLTPAQ and Physical Activity form. Study staff will determine the initial power wattage for the test based on the answers to these surveys.

Sitting with both feet on the floor and legs uncrossed, manual blood pressure will be obtained two separate times, five minutes apart after 10 minutes of seated rest. Blood pressure measurements with an average of $<140/<90$ is to be considered safe to continue with testing [20]. After the blood pressure measurement is obtained, the patient will have their temperature measured one time and their height and weight measured two times without shoes. The HR monitor will be fitted on the patient to continuously monitor HR throughout exercise. The rate of perceived exertion (RPE) scale will be explained to the patient. The patient will mount the stationary bike and study staff will help adjust the seat, handlebars, and pedals to the comfort of the patient. Study staff will then place a fitted silicone one-way rebreathing mask on the patient to measure their metabolic data using indirect calorimetry via the metabolic cart that captures expired gasses (O_2 and CO_2). Capillary blood lactate levels will be obtained by finger stick for the lactate analyzer.

Participants will sit on the stationary bike for two minutes to capture expired gases and blood lactate levels at rest. At the end of rest, the patient will begin pedaling at a self-selected steady cadence between 60 and 100 RPMs at the initial power wattage determined by study staff. The patient will pedal at this cadence for the remainder of the test. Every three minutes, the power output will increase by 15 Watts. With thirty seconds remaining in each stage, blood lactate levels will be measured in duplicate and study staff will prompt the participant to quantify their effort using the RPE scale. When the duplicate blood lactate measurements exceed 4.0 mmol/L, the participant will complete the current stage and end the test.

After completion of the test, study staff will calculate the power output that is equivalent to 1.1x the wattage at which patients' lactate exceeded 4.0 mmol/L (P_{LT+}). This power output will be used as the exercise intensity for subsequent on-off kinetics testing.

Visit #2+: On-Off Kinetics Testing

Using the reference photo taken at the first visit, mark the NIRS device location and use the ultrasound to measure and record ATT. If the ATT measurement matches the ATT from the first visit, secure the NIRS device with tape as previously described. The participant will fill out the BFI, PROMIS Global Health, and Physical Activity Follow Up forms and update contact information if needed.

The participants will sit on the bike for a two-minute rest. Participants will begin pedaling for a warmup at 0 Watts for 2 minutes at a self-selected steady cadence of 60-100 RPM.

After the 2-minute warm up, the power output will increase to P_{LT+} . Participants will cycle at the same self-selected cadence for 2 minutes ("on-kinetics"). Thirty seconds before the end of the on-kinetics stage, participants will be asked their RPE. At the end of the 2-minute on-kinetics period, participants will stop pedaling and study staff will remove their non-measured leg from the pedal to rest on a box in a relaxed, extended position to aid in total relaxation and remove any additional movement of the measured leg. During the rest period, participants will remain in recovery sitting on the bike for 2 minutes ("off-kinetics" stage). Participants subsequently will start pedaling at their self-selected cadence for their next 2 minute "on-kinetics" stage, followed by another 2-min "off-kinetics" period. This cycle of exercise followed by rest, referred to as on-off kinetics, will repeat for a total maximum of 3 times, or unless the patient requests to stop.

Outcome measures

Collection of biometrics at each visit

Study staff will measure O₂Hb, HHb, and TSI, via the NIRS PortaMon device during the on-off kinetics protocol. We also will measure ventilatory whole-body components including O₂ and CO₂ via the Parvomedics metabolic cart. Participants' perceived exertion to the exercise will be measured via RPE during every exercise stage.

NIRS data will be collected using Artinis Medical System's Oxysoft software at a frequency of 10hz. A differential pathlength factor (DPF) value of 4 will be selected, as recommended by Artinis (Einsteinweg, Netherlands). The PortaMon will be placed on the vastus

lateralis of participants for a period of at least 10 minutes prior to beginning exercise in accordance with the recommendation of Cortese L, et al. to allow calibration of the PortaMon [53].

Throughout data collection, researchers will closely observe for excess movement from participants that may affect the data collection. These sections will be removed from analysis. After data collection, a moving average with a filter width of 1.5 seconds will be applied to smooth leg movement artifacts that occurred during cycling. Data cleaning and analysis will be conducted using R (R Core Team, 2020) and RStudio (Rstudio Team, 2020).

Data analysis and Statistical analysis

Previous literature has shown that oxygenation levels at rest after moderate and/or high intensity exercise or after occlusion follows an asymptotic curve of the form [54]:

$$y = A + (B_0 - A) e^{-t/\tau} \quad (2)$$

Where y is the oxygenation at time t , A is the oxygenation as t approaches infinity, t is time measured in seconds, B_0 is the value at $t=0$, and τ is the time constant. For each rest period, we will run an asymptotic regression for O2Hb, HHb, and TSI by time in seconds to find the coefficient estimate for τ .

Each data set will contain three rest periods; therefore, each data set will have three τ values for each variable. We will average the τ values to obtain one average rest τ for O₂Hb, HHb, and TSI per data set. Since continuous wave NIRS devices measure oxy- and deoxyhemoglobin as changes from baseline, raw oxy- and deoxyhemoglobin values will have no meaning and are not comparable except when measured as changes over time or as τ values.

We will analyze the ΔO_2Hb , ΔHHb , and ΔTSI , calculated as the change in steady state levels of O₂Hb, HHb, and TSI respectively from work to rest, with steady state values calculated as the mean value of the final thirty seconds of the stage. For each data set of one on-off kinetics, there will be three work/rest period pairs therefore we will calculate three delta values and average the three delta values to obtain one delta value for O₂Hb, HHb, and TSI per data set. The three work/rest transitions will allow for reliability testing with intraclass correlation coefficients. For participant data to be included in the final analysis, the participant will need to complete at least three on-off kinetic laboratory visits. Each participant will complete an on-off kinetics at least two weeks apart, but not more than one month apart in accordance with their prescribed chemotherapy treatment regimen. Each on-off kinetics will correspond with the first infusion of a chemotherapy cycle. To allow participants a maximum amount of time to recover from infusions before participating in exercise, the corresponding on-off kinetics takes place within 48 hours of the first infusion of the subsequent chemotherapy cycle. Since chemotherapy treatments vary depending on oncologist recommendation, each participant may complete different lengths of treatment, resulting in each participant having different numbers of data points. This will prevent us from using traditional statistical analysis such as repeated measures ANOVA. Since it is not time itself, but rather the compilation of chemotherapy infusions over time that we predict will

cause changes in measures of mitochondrial oxidative function, we will treat the number of chemotherapy cycles as an ordinal variable in this analysis. We will complete an analysis using mixed effects models to predict τ and deltas from the number of chemotherapy treatments with a random intercept for patients.

Data Management Plan

Patient health information (PHI) will be obtained directly from the patient and the electronic medical record (EMR). This information will only be obtained after documented informed consent has been provided by the patient. PHI will be stored in the Prisma Health RedCap®, a HIPAA compliant cloud platform. All data will be housed within the Prisma Health system. Surveys and questionnaires will be stored in a locked file cabinet in a locked room in the Human Performance Laboratory.

Trial Oversight

This study has been approved by the Institutional Review Board at the Prisma Office of Research Compliance and Administration (ORCA). All adverse events (AE) and serious adverse events (SAE) will be recorded from the start of the visits, beginning with the first visit for lactate threshold testing and throughout completion of exercise visits, or when the participant has elected to no longer participate. The investigators will record and report all AE and SAE to the

IRB within 24 hours. Fatal or life threatening unexpected adverse reactions will be reported to Prisma Health IRB immediately.

Discussion

With limited studies of mitochondrial function (e.g. oxygen delivery and utilization) during cancer chemotherapy, opportunity exists to address mechanisms of cachexia and cancer-related fatigue using NIRS. To date, two main studies used NIRS with cancer populations. However, neither of the research teams collected data during active chemotherapy treatment, and they only measured steady-state values during exercise as opposed to collecting oxygen kinetics during recovery and exercise. Additionally, the independent variables included treatments additional to chemotherapy, including radiation and immunotherapy. The variation in independent variables may have been the reason for limited changes in the NIRS outcome variables. Ederer, et al [29] found significant differences in HHb and total hemoglobin with a limited sample size of 8 cancer survivors compared to matched controls, while Grigoriadis et al. [30] found no significant differences in any of the NIRS variables. Understanding oxygen delivery and utilization kinetics with ventilatory and local NIRS measurements during chemotherapy could unlock mechanistic understanding of mitochondrial dysfunction. Our study will be the first to recruit at least 30 patients diagnosed with cancer and capture both baseline and longitudinal NIRS measurements throughout the entire chemotherapy protocol.

375 The study's design must consider 1) exercise tolerance levels to obtain fatigue and
376 recovery kinetics for patients going through chemotherapy and 2) rapid recruitment of patients
377 for baseline measurements. We recognize that the level of conditioning our patients have at
378 baseline may be reduced as treatment progresses. Therefore, we chose a protocol that was
379 tolerable to patients, which is to cycle to 10% above their lactate threshold level; both before
380 discontinuing the LT test and for the on/off kinetics tests. This intensity elicits an appropriate
381 mitochondrial response in the exercising muscle while allowing for a reasonable exercise
382 intensity that a patient can complete despite anticipated treatment deconditioning. Additionally,
383 because patient recruitment will occur at the time of diagnosis, a team of referral coordinators,
384 nurse navigators, and oncologists need to identify newly diagnosed patients, and be prepared,
385 through a "chemo-teach", to consent interested patients in a timely manner.

386 A few limitations are to be considered regarding the validity of the PortaMon by Artinis
387 Medical Systems. First, the device is designed to accurately penetrate 20 mm of depth through
388 adipose tissue and into the muscle belly. If the subcutaneous adipose tissue thickness is greater
389 than 20 mm, the infrared signal from the device will not penetrate the skeletal muscle body and
390 be unable to obtain accurate measurements. Our protocol minimizes this concern by excluding
391 participants who have greater than 20 mm adipose tissue subcutaneous to the vastus lateralis, and
392 by standardizing device placement on the leg from test to test to increase reliability and validity
393 of repeated measures measurements. Ambient light can interfere with the signal quality, however
394 Oxysoft provides real-time data acquisition (DAQ) measurements. Using the manufacturer's
395 recommendation, channels with DAQ higher than 97% will be removed from analysis.

Results from this pilot study will provide information on the feasibility of capturing on/off kinetics mitochondrial function data longitudinally using NIRS in patients newly diagnosed with breast or gynecological cancer, provide preliminary data for future extramural funding, and inform the scientific community of results through dissemination via conference presentations and peer-reviewed publications.

Trial Status

The trial is currently in the data collection phase with 13 participants who have completed the protocol. The study is planned to continue to enroll test subjects until n = 30.

580 **Author Contributions**

581 Randy Hutchison: Co-Principal Investigator, NIRS expert, concept for research design and data
582 analysis plan, contributory writer

583 Shannon Smith: Medical student researcher, supported investigator-led study design through
584 performing literature review, assisted in pilot data collection, contributory writer

585 Chloe Caudell: Medical student researcher, supported investigator-led study design through
586 performing literature review, assisted in pilot data collection, contributory writer

587 Sara Biddle: Data analyst, writer, researcher, contributory writer

588 W. Larry Gluck, MD: Co-Investigator, medical director of Prisma Health Cancer Institute,
589 primary clinical contribution and oversight, contributed to conceptual study design for
590 chemotherapy-related fatigue and mitochondrial dysfunction in patients with cancer.

591 Jennifer Trilk (corresponding author): Co-Principal Investigator, co-concept for research design
592 and data analysis plan, co-author

	Study Period						
	Enrollment	Post Allocation					Close-out
TIMEPOINT**	-t1 (with Oncology Research Nurse)	t1 (Lactate Threshold Baseline Testing in Human Performance Lab)	t2 (baseline on- off kinetics test, pre- chemotherapy cycle 1)	t3 (pre- chemothe- rapy cycle 2)	t4 pre- chemotherapy cycle 3)	Etc. until chemotherapy cycles complete	Post Test
ENROLLMENT:							
Eligibility screen	x						
Informed Consent	x						
-see inclusion/exclusion criteria (Table 1)	x						
-feasibility: capable, willing to participate	x						
-Godin Leisure Survey		x					
-Ultrasound for adipose tissue thickness		x					
-Mini Mental State Exam		x					
Allocation (N/A, no intervention, observational trial only)							
INTERVENTIONS: Observational study, no interventions, gathering assessments throughout chemotherapy based on oncology prescribed, chemotherapy standard of practice							
ASSESSMENTS:							
[Baseline variables]							
Global Heath Promis Survey		x	x	x	x	x	x

Figure 1A Schedule Enrollments

Brief Fatigue Inventory		X	X	X	X	X	X
Physical Activity		X	X	X	X	X	X
[Outcome variables]							
NIRS Data (O2Hb, HHb, TSI, τ , etc.)		X	X	X	X	X	X
Ventilatory Metabolic Measurements (VO2, VCO2, etc.)		X	X	X	X	X	X
Heart Rate		X	X	X	X	X	X
Rate of Perceived Exertion		X	X	X	X	X	X
[Other data variables]							
Height		X	X	X	X	X	X
Weight		X	X	X	X	X	X
Blood Pressure		X	X	X	X	X	X
Temperature		X	X	X	X	X	X
Ultrasound for adipose tissue thickness		X	X	X	X	X	X
