Abstract

Objectives

The number of *Anopheles* mosquito bites a person receives determines the risk of acquiring malaria
and the likelihood of transmitting infections to mosquitoes. We assessed heterogeneity in *Anopheles*
biting and associate and the likelihood of transmitting infections to mosquitoes. We assessed heterogeneity in Anopheles
biting and associated factors in two settings in Uganda with different endemicity.
Methods
Plasmodium falciparum parasites

Introduction

Infectious diseases typically exhibit heterogeneous transmission [1]. Certain individuals or
populations may experience a disproportionately higher number of infection events. In mosquito-
borne diseases, differences in mo exist between individuals from the same household [2, 3]. Non-random human biting frequency pathogen exposure. Whilst mosquito exposure on a household level can be measured through
mosquito catches that estimate mosquito density, considerable variation in mosquito exposur
exist between individuals from the same h particular exposure. Whilst mosquito density, considerable variation in mosquito exposure
exist between individuals from the same household [2, 3]. Non-random human biting frequence
patterns are observed across mosquito sp exist between individuals from the same household [2, 3]. Non-random human biting frequency
patterns are observed across mosquito species including *Anopheles [4-10], Culex* [10] and *Aedes* [2,
3, 11, 12].
The likelihood externs are observed across mosquito species including *Anopheles [4-10], Culex* [10] and *Aedes*
3, 11, 12].
The likelihood of receiving a mosquito bite depends on both host attractiveness and availability.
availability i

3, 11, 12].
The likelihood of receiving a mosquito bite depends on both host attractiveness and availability. Host
availability is determined by host defensive behaviour and the amount of time spent unprotected --, --, ---,

Matching human DNA in mosquito bloodmeals. A common approach herein is profiling panel
short tandem repeats (STRs) and comparing STR profiles within a human population to mosquidoodmeals [4, 6, 8, 14]. Using the existing m short tandem repeats (STRs) and comparing STR profiles within a human population to mosquito
bloodmeals [4, 6, 8, 14]. Using the existing methods, matching STR profiles requires an exact, or r
exact overlap of bloodmeal an bloodmeals [4, 6, 8, 14]. Using the existing methods, matching STR profiles requires an exact, or near-
exact overlap of bloodmeal and human STR profiles. This impairs the ability to match multi-source
bloodmeals that may digested their blood meals [20, 21]. Recently, a novel approach using log-likelihood ratios to match exact overlap of bloodmeals that may comprise up to 22% of mosquito blood meals [19] and to match incomplete S
profiles that can primarily occur in low-blood volume mosquitoes [8] or in those that have partially
digested t profiles that can primarily occur in low-blood volume mosquitoes [8] or in those that have partially digested their blood meals [20, 21]. Recently, a novel approach using log-likelihood ratios to match STR profiles was dev promed that can primarily cools that can be accured volume mosquitoes [9] or in the those particle particle,
digested their blood meals [20, 21]. Recently, a novel approach using log-likelihood ratios to match
STR profiles digested their theory of the state of the state of the STR profiles was developed [22]. This log-likelihood approach enables matching of incomplete and
multi-source STR profiles.

without an apparent di of study participants receiving 67.0% of the observed mosquito bites per trapping night (Figure 4B)
without an apparent difference between study sites (Supplementary Figure 2).
Variation in mosquito biting is consistently of study ideas in the original participant of the observed most
increase is study sites (Supplementary Figure 2).
To better understand drivers of heterogeneity in nightly bites, we investigated participant population

Variation in mosquito biting is consistently related to human age

Variation in mosquito biting is consistently related to human age
To better understand drivers of heterogeneity in nightly bites, we investigated
demographics in relation to mosquito biting. Whilst taking into account the demographics in relation to mosquito biting. Whilst taking into account the number of household
occupants present during trapping nights, children below the age of 5 years accounted for the lowest
proportion of nightly bit demographics in relation to mosquito binary trains taking into account its taking of comparison of the low
proportion of nightly bites (19.9%), followed by children aged 5-15 years (42.2%) and individuals
aged 16 years or proportion of nightly bites (19.9%), followed by children aged 5-15 years (42.2%) and individuals
aged 16 years or older (37.9%, Figure 5A). The received bites per trapping night was significantly
lower in children aged b aged 16 years or older (37.9%, Figure 5A). The received bites per trapping night was significantly
lower in children aged below 5 years compared to the two older age groups (P < 0.0001); the
difference between children age Example 16 years of the two older age groups ($P < 0.0001$); the difference between children aged 5-15 years and individuals aged 16 years or above was not statistically significant ($P = 0.25$). The proportion of nightly b difference between children aged 5-15 years and individuals aged 16 years or above was not statistically significant ($P = 0.25$). The proportion of nightly bites for female participants was 43.3% statistically significant (P = 0.25). The proportion of nightly bites for female participants was 43.3%

compared to 56.7% for male participants, and the received number of bites per trapping night was significantly lower for female participants (P = 0.001, Figure 5A). Gender-related differences in mosquito exposure were grea shipped and the set of the set of the set of the sequito exposure were greatest in Tororo-Busia households where male individuals aged 16 or above were responsible for 29.1% of the observed bites, compared to 13.1% for fem or above were responsible for 29.1% of the observed bites, compared to 13.1% for female individual
of the same age group.
We next used a multilevel approach to assess the effect of potential risk factors on the number of
r

of the same age group.
We next used a multilevel approach to assess the effect of potential risk factors on the number of

Conclusions

Most a non-random phenomenon and certain human intertains are distributed into
others. In vector borne diseases such as malaria, heterogeneity in mosquito biting may translate inte
heterogeneity in contributions to the hum beterogeneity in contributions to the human infectious reservoir. In the present study, we assessed
heterogeneity in mosquito biting in relation to population demographics in two different endemicity
settings. We observed heterogeneity in mosquito biting in relation to population demographics in two different endemicity
settings. We observed that children below 5 years were bitten the least compared to school-age
children (5-15 years) and a heterings. We observed that children below 5 years were bitten the least compared to school-age
children (5-15 years) and adults (≥16 years). These patterns were consistent in two sites of different
malaria endemicity.
Pre settings. We observed that children by pair in the least that the least compared to school-age
children (5-15 years) and adults (216 years). These patterns were consistent in two sites of differe
malaria endemicity.

Malaria entistical statistic Previous attempts to understand patterns in mosquito uning previous to the exclusion of partially dige
matching human DNA in mosquito bloodmeals and were limited by the exclusion of partially dige
and multi-sourced bloodme and multi-sourced bloodmeals [5, 6]. In this study, we investigated mosquito biting heterogeneity
using a novel statistical approach that allows for the inclusion of partially digested and multi-sourced
bloodmeals [13, 22] and movel statistical approach that allows for the inclusion of partially digested and multi-sourced bloodmeals [13, 22]. From all collected blood fed mosquitoes, 86.8% of blood meals were successfully typed as human blood bloodmeals [13, 22]. From all collected blood fed mosquitoes, 86.8% of blood meals were
successfully typed as human blood meals of which 78.8% showed a complete STR profile from a
single human that was linkable in 80.2% of bloodmeals [13, 22]. From all collected blood fed mosquitoes, 86.8% of blood meals were
successfully typed as human blood meals of which 78.8% showed a complete STR profile from a
single human that was linkable in 80.2% of single human that was linkable in 80.2% of the cases. Of the typed blood meals, 10.4% was single
sourced yet partially digested and 10.7% was observed to have multiple human blood sources. V
successfully identified the hum s individual buman that was linked blood blood meals. Of the chronical value of the samples by $\mathsf{z}_{0.0}$ successfully identified the human source for 82.1% of partially digested bloodmeals and we identified
at least one human source for 89.9% of multi-sourced bloodmeals. By including partially digested and
multi-sourced blood at least one human source for 89.9% of multi-sourced bloodmeals. By including partially digested and
multi-sourced bloodmeals we increased our sample size of informative mosquito samples by 28.8%,
thereby allowing a more a multi-sourced bloodmeals we increased our sample size of informative mosquito samples by 28.8%,
thereby allowing a more accurate analysis of mosquito biting heterogeneity amongst different
population groups.
Characterisati man exact and commenced bloodmeals of mosquito biting heterogeneity amongst different
population groups.
Characterisation of multi-sourced bloodmeals can also have relevant implications for malaria
transmission estimates [

thereby allowing propulation groups.
Theracterisation of multi-sourced bloodmeals can also have relevant implications for malaria
Theracterisation estimates [9]. If certain demographic populations are more likely to experi propulation groups.
Characterisation of
transmission estima
meals that are incor
that results in interi transmission estimates [9]. If certain demographic populations are more likely to experience blood
meals that are incomplete, for instance by increased uptake of interventions or defensive behaviour
that results in interru that results in interrupted/partial bloodmeals, ignoring multi-sourced bloodmeals can lead to biase
biting estimates. In addition, entomological inoculation rate estimates are based on the sporozoite
infection rate and hum that results in interrupted/partial bloodmeals, ignoring multi-sourced bloodmeals can lead to biased
biting estimates. In addition, entomological inoculation rate estimates are based on the sporozoite
infection rate and hu biting estimates. In addition, entomological inoculation rate estimates are based on the sporozoite
infection rate and human biting rate, which assumes that a mosquito takes a single blood meal per
gonotrophic cycle. If mo infection rate and human biting rate, which assumes that a mosquito takes a single blood meal per
gonotrophic cycle. If mosquitoes take multiple blood meals and would expel sporozoites at each
feeding attempt, this would i infering and trophic cycle. If mosquitoes take multiple blood meals and would expel sporozoites at each
feeding attempt, this would increase number of infected bites a population is exposed to.
In our setting, young childr

feeding attempt, this would increase number of infected bites a population is exposed to.
In our setting, young children (<5 years) were less frequently bitten by *Anopheles* mosquitoes that
older individuals. This observe feeding attempt, the mean matter changer of interests and to perpendance inperention
In our setting, young children (<5 years) were less frequently bitten by Anopheles mosquit
older individuals. This observed age pattern i In our setting, young children (<5 years) were less frequently bitten by Anopheles mosquitoes than
older individuals. This observed age pattern in *Anopheles* biting heterogeneity is in line with previou
work in Malawi [6] work in Malawi [6], Kenya [5, 13] and Papua New Guinea [14]. Previous studies in Thailand [11] and Puerto Rico [12] observed similar age patterns in bites of Aedes aegypti mosquitoes; adults were Puerto Rico [12] observed similar age patterns in bites of Aedes aegypti mosquitoes; adults were

bitten more frequently than expected based on a random distribution. In addition to participant age,
body surface area has been correlated with an elevated biting rate by Aedes [12] and Anopheles [4,
28] mosquitoes. Large body surface area has been correlated with an elevated biting rate by Aedes [12] and Anopheles [4,
28] mosquitoes. Larger individuals with higher metabolic rates may release more CO₂ and skin-
volatiles that are importa

undatiles that are important mosquito attractants [29, 30].

participants with a microscopica
night. This could suggest that m Recent work from Kenya [13] reported higher biting rates in F. *Julei purum* infected numan individuals
compared to uninfected individuals. Using a similar approach, we observed a comparable effect in
participants with a m participants with a microscopically detected P. falciparum infection -28 or +7 days from the trapping
night. This could suggest that mosquitoes have a preference to feed on infected people; it is however participants with a microscopically detected P. Jutelparam infection -28 or +7 days from the trapping
night. This could suggest that mosquitoes have a preference to feed on infected people; it is however
not possible to ru not possible to rule out that other factors – for example related to behaviour – influence both risk of
blood-stage infection and mosquito biting. Relevantly, the association between mosquito biting and
human infection sta blood-stage infection and mosquito biting. Relevantly, the association between mosquito biting and human infection status did not survive sensitivity analyses in our study. Importantly, our study was human infection status did not survive sensitivity and μ in our study. Importantly, our study was μ

not designed to consess the effect of a real-time *P. falciparum* infection on mosquito biting rates. Future studies on mosquito biting heterogeneity could therefore benefit from real-time data on human infection, ideally required to assess the effect of a real-time P. Jale, param infection on mosquito biting rates. Future
studies on mosquito biting heterogeneity could therefore benefit from real-time data on human
infection, ideally also i infection, ideally also including gametocyte presence. Moreover, the work from Kenya also show
that infectious mosquitoes bite infected human individuals [13]. Our study was not designed to
evaluate this, since mosquito le infectious mosquitoes bite infected human individuals [13]. Our study was not designed to
evaluate this, since mosquito level sporozoite data was not available for Nagongera collections and
sporozoite positivity was very l that infectious mosquito level sporozoite data was not available for Nagongera collections as
sporozoite positivity was very low for Tororo-Busia collections.
Our study had several additional limitations. Firstly, we colle

evaluate they intermed interpretent since most around to this, since the since in this subspace of the sporozoite positivity was very low for Tororo-Busia collections.
Our study had several additional limitations. Firstly, our study had several additional limitations. Firstly, we collecte factors identified for mosquito biting rates may differ for mosquite factors identified for mosquito biting rates may differ for mosquite related to differ Factors identified for mosquito biting rates may differ for mosquitoes that bite outdoors, potentially
related to differences in host availability. Importantly, previous work in Papua New Guinea used
outdoor barrier screen factors in that in the straight formula for mosquitors in the strategies of that the strategies prediction, performance in the outdoor barrier screens to catch blood fed *Anopheles* mosquitoes and observed similar age and outdoor barrier screens to catch blood fed *Anopheles* mosquitoes and observed similar age and
gender patterns [14]. In addition, it is very likely that we did not capture all mosquito exposure; s
mosquito exposure will ha barrier screens to catch blood fed Anopheles mosquitoes and observed similar age and
gender patterns [14]. In addition, it is very likely that we did not capture all mosquito exposure;
mosquito exposure will have occurred gender patterns [14]. In addition, it is very likely that we did not repeat summing mosquito exposure will have occurred outside sampling days and biting that did not result in a
bloodmeal but can nevertheless involve spor mosquito enperior in manner eccurred entries emp_{ping} any came aning that in a necessarility bloodmeal but can nevertheless involve sporozoite inoculation [35, 36], will have gone undeted
Nevertheless, we are confident th Nevertheless, we are confident that the mosquitoes collected resemble a random sample of the
overall mosquito population and the undetected bites are likely to follow the patterns observed
using the collected mosquitoes. F overall mosquito population and the undetected bites are likely to follow the patterns observed
using the collected mosquitoes. Finally, blood samples were collected from individuals in
participating households and we did overally, blood samples were collected from individuals in
participating households and we did no collect blood samples from neighbouring households.
Including human blood samples from outside the study households could ha participating households and we did no collect blood samples from neighbouring householn
Including human blood samples from outside the study households could have increased
mosquito matching rates, which would have been i participating in all the the meaning endeal collect blood products and including human blood samples from outside the study households could have increased the
mosquito matching rates, which would have been interesting esp Including mosquito matching rates, which would have been interesting especially for multi-sourced blood
Inconclusion, we observed that adults and school-age children were disproportionally bitten
Anopheles mosquitoes in tw

meals.
In conclusion, we observed that adults and school-age children were disproportionally bitten by
Anopheles mosquitoes in two malaria endemicity settings in Uganda. Previous work in the same
