23

## 24 INTRODUCTION

25 Typhoid fever (typhoid) is an enteric bacterial infection caused by *Salmonella enterica* serovar Typhi  
26 (*Salmonella* Typhi; *S. Typhi*). It is one of the most common bacterial causes of acute febrile illness in  
27 the developing world,[1] with an estimated 10.9 million new cases worldwide and 116.8 thousand  
28 deaths in 2017.[2,3] Paratyphoid fever caused by *Salmonella enterica* serovars Paratyphi A, B and C  
29 (*S. Paratyphi*) results in a disease that can have an identical clinical syndrome to typhoid fever,[4] but  
30 is often less severe.[5] Typhoid fever is most common in South Asia and sub-Saharan Africa, with  
31 children predominantly affected. Like many febrile illnesses, typhoid presents with non-specific  
32 symptoms and signs, especially in its early stages. In routine healthcare settings in low- and middle-  
33 income countries (LMIC), typhoid fever is commonly suspected and treated empirically with  
34 antibiotics.[6] This overuse of antibiotics creates a selective pressure for the development of  
35 antimicrobial resistance (AMR),[7] that has resulted in the emergence and spread of typhoid strains  
36 that are resistant to all first-line antibiotics.[8] Similarly, the low specificity of current rapid  
37 diagnostic tests (RDTs) can lead to an over diagnosis of typhoid fever that may result in the overuse  
38 of antibiotics and delay the proper treatment for underlying conditions. For example, the use of the  
39 Widal test during an outbreak of acute febrile illness in Nepal led to misdiagnosis of typhoid which  
40 delayed the appropriate treatment of the causative agent (scrub typhus), resulting in dozens of  
41 deaths.[9] The potential harms of current typhoid RDTs are compounded by the fact they are widely  
42 available, cheap and easy to use.[10]

43

44 Various aspects of *S. Typhi* biology make diagnosis by standard laboratory methods challenging. *S.*  
45 *Typhi* is able to bypass the gastrointestinal mucosal barrier that restricts other enteric bacteria and can  
46 evade the typical innate immune responses with limited activation of inflammatory pathways.[11] *S.*  
47 *Typhi* infection begins with invasion of the mucosa of the terminal ileum, and the organism is thought  
48 to only be transiently present in the blood before dissemination throughout the reticuloendothelial  
49 system into the bone marrow, liver and spleen.[12] The bacterial load in peripheral blood peaks in the  
50 first week of illness,[13] but is still very low with a median of 0.1-1.0 colony forming units (CFU)/mL  
51 in symptomatic patients.[14] This concentration is difficult to detect by blood culture or PCR,  
52 resulting in lower sensitivity for these diagnostic tests. *S. Typhi* is a member of the Enterobacteriaceae  
53 family, and antibodies that have been produced in response to prior infections with other  
54 Enterobacteriaceae tend to cross-react with *S. Typhi*,[12] due to significant conservation of surface  
55 antigens. This cross-reactivity lowers the specificity of antibody-based diagnostic assays that  
56 otherwise are well suited for a simple, rapid and inexpensive test format. Compounding the challenge,  
57 the muted immune response that occurs through expression of the Vi capsular polysaccharide[12] may  
58 further hinder the utility of serological tests for typhoid diagnosis.

59

60 In clinical settings supported by a microbiology laboratory, invasive typhoid infection is confirmed  
61 through isolation of *S. Typhi* from blood cultures, but this is relatively expensive, can take >48 hours,  
62 has low sensitivity, and requires laboratory infrastructure and trained staff that are not commonly  
63 available in LMIC where typhoid is most prevalent.[15] Bone marrow cultures have high sensitivity  
64 for detection of *S. Typhi* but are not routinely used because of the invasive techniques needed to  
65 obtain bone marrow aspirates. PCR testing for typhoid is expensive and has a low diagnostic  
66 sensitivity when used on peripheral blood samples.[16] Other available point-of-care (POC)  
67 diagnostic tests include the Widal test,[17] TUBEX,[18] Typhidot,[19] Test-it Typhoid,[20] and the  
68 Typhoid-Paratyphoid diagnostic assay (TPTest). However, these tests all have significant drawbacks  
69 that limit their clinical use.

70

71 A Cochrane review of the accuracy of the commercially available antibody-based rapid RDTs showed  
72 moderate sensitivity and specificity for the TUBEX colorimetric test that detects anti-O:9 antibody  
73 titres (78%, 87%), the Typhidot dot enzyme linked immunosorbent assay (ELISA) that measures IgG  
74 and IgM antibodies against the outer membrane proteins of *S. Typhi* (84%, 79%) and the Test-it  
75 Typhoid immunochromatographic lateral flow assay that detects IgM antibodies against *S. Typhi* O  
76 antigen (69%, 90%).[21] The TPTest is a newer serological test that detects circulating IgA using  
77 ELISA with a sensitivity and specificity of >95%.[22] But it takes 24-48 hrs hours to produce a result,  
78 and requires blood culture equipment not widely available in resource-limited settings.[14,22] Due to  
79 the limited sensitivity of all current typhoid POC tests they cannot be relied upon to guide treatment  
80 prescribing.

81

82 If developed and implemented effectively, an accurate typhoid RDT could reduce morbidity and  
83 mortality through faster diagnosis. Further, it could help to reduce the overuse of antibiotics that  
84 contributes to the emergence and spread of multidrug resistant strains of *S. Typhi* and other bacteria.  
85 In recent years, novel approaches have been described to develop typhoid diagnostic tests with  
86 improved accuracy in resource-limited settings, including serological, molecular, metabolomic,  
87 proteomic, and transcriptomic methods.[7] For example, a recent study has shown that IgA and IgM  
88 against *S. Typhi* lipopolysaccharide (LPS) may be a specific marker of acute typhoid infection and is  
89 a promising target for diagnostic test development.[23]

90

91 As the need for appropriate fever case management becomes more apparent,[24] the need for  
92 improved typhoid diagnostics suitable for use in low-resource environments becomes more pressing.  
93 Building on the recent momentum around improved typhoid surveillance[25] and advances in typhoid  
94 detection,[1] this report describes the development of a target product profile (TPP) in an attempt to  
95 define the diagnostic needs for this important pathogen. The TPP is intended to guide product  
96 development and to ensure an optimized solution that meets the needs of endemic countries and

97 results in tangible improvements in patient management. In addition, the TPP aims to re-invigorate  
98 the discussion of diagnostics as a crucial part of the global typhoid agenda. This report focuses on the  
99 process of TPP development with an emphasis on key test characteristics and discussion points  
100 identified by typhoid experts and experienced stakeholders.

101 **METHODS**

102

103 **Data gathering**

104 A structured review of relevant literature related to *Salmonella* Typhi diagnosis was performed to  
105 develop a draft TPP with minimal and optimal desired characteristics for a next-generation typhoid  
106 diagnostic test. The test characteristics chosen for the TPP were selected based on previous TPPs  
107 published by the Foundation for Innovative New Diagnostics (FIND)[26,27], and include the scope,  
108 target population, intended use, expected test performance, as well as operational and financial  
109 parameters (Table 1). Each desired test characteristic was classified as either a minimum requirement  
110 that a test must meet to be useful for healthcare providers treating patients in resource-limited settings,  
111 or an optimum threshold that would make the test highly desirable for both healthcare providers and  
112 patients. The Ovid Medline database was accessed on June 21, 2018 using the Medical Subject  
113 Heading (MeSH) “Typhoid fever” and the subheading “Diagnosis”. Results were restricted to English  
114 language articles published in the previous 10 years. Titles and abstracts of retrieved articles were  
115 scanned for relevance, with articles of interest thoroughly reviewed by RM for content relevant to the  
116 TPP. Additional documents were identified by searching for “typhoid” on the websites of the  
117 Cochrane library, WHO, and FIND, and by screening references and studies that cited articles  
118 selected in the initial search. Expert stakeholders to be contacted for the Delphi survey were identified  
119 as part of the literature review.

120

121 **Delphi survey**

122 Stakeholders were contacted for input on the draft TPP using a Delphi survey. Stakeholders included  
123 specialists in clinical medicine (n = 14), laboratory medicine (n = 2), microbiology (n = 6),  
124 diagnostics (n = 11) and public health and global health. An online survey (supplementary table 1)  
125 was used and respondents were asked to rate their agreement with each of the TPP characteristics  
126 using a Likert scale (1 = strongly disagree, 2 = disagree, 3 = neither agree nor disagree, 4 = mostly  
127 agree, 5 = fully agree). A consensus agreement was defined as  $\geq 75\%$  of respondents who either  
128 mostly or fully agreed with a TPP characteristic. Results from the first round of the survey (Oct/2018)  
129 were used to refine the TPP, and a second draft of the TPP was distributed (Nov/2018) to all initial  
130 participants as well as two additional stakeholders identified after the first round of the survey was  
131 completed.

Operational characteristics	Kit configuration Reagent preparation Operating conditions Transportation and storage stability Equipment (Instrumentation external to test) External maintenance Calibration Internal/ Process control Batch/Quality control Power requirements Water requirement Waste disposal Bio-safety Training requirements Cost per test

140

141 **RESULTS**

142 An Ovid Medline search using the MeSH “Typhoid fever” produced 10,698 results, with 1,558 results  
143 for the subheading “Diagnosis”. Limiting search results to English language articles published after  
144 January 1<sup>st</sup>, 2008, provided 298 articles that were screened for relevance. Additional documents were  
145 included as outlined in the Methods and selected articles were thoroughly reviewed to develop a draft  
146 typhoid TPP with minimum and optimum criteria for the test characteristics in Table 1.

147

148 Feedback on the draft TPP was obtained from key stakeholders through the first round of the Delphi  
149 survey, with 40 stakeholders contacted and 19 (19/40, 48%) completed surveys received. Survey  
150 respondents had experience working in low resource settings in Africa, the Americas, Europe, the  
151 Eastern Mediterranean, South-East Asia and the Western Pacific region. Consensus agreement of  
152  $\geq 75\%$  was achieved for 34/36 (94%) TPP criteria. TPP criteria that generated the most discussion in  
153 the Delphi survey were related to the scope of the test including the goal, target population, level of  
154 the health care system, diagnostic sensitivity and specificity, as well as cost. Based on feedback from  
155 survey respondents, “multiplexing” was removed as a TPP characteristic, and the remaining minimum  
156 and optimum TPP criteria were revised. For criteria that had achieved consensus agreement, revisions  
157 were made if survey respondents provided compelling suggestions for improvement.

158

159 A second draft of the TPP was distributed to the 19 people who responded to the initial Delphi survey,  
160 and two additional stakeholders identified after completion of the first round. A total of 12 completed  
161 surveys were received from 13 stakeholders, including two who submitted a joint survey, with  
162 consensus agreement achieved for 33/35 (94%) TPP characteristics. The two criteria that did not meet  
163 the consensus threshold were the target level of the health system and diagnostic sensitivity, both of  
164 which received 67% agreement. Survey respondent feedback was used to revise these two criteria,  
165 and to make minor changes to four criteria that had  $\geq 75\%$  agreement, before inclusion in the final  
166 version of the TPP presented in Tables 2, 3 and 4.

167

168 **Scope of test**

169 Delphi survey feedback emphasized that a next-generation RDT for typhoid fever should not focus  
170 solely on the diagnosis of *S. Typhi*. To reduce the empiric use of antibiotics that generates selective  
171 pressure for AMR, a typhoid RDT would ideally be combined with diagnostics for malaria and other  
172 causes of acute febrile illness as part of a case management algorithm (Table 2). Due to the similar  
173 clinical presentation and the changing epidemiology of *S. Typhi* and *S. Paratyphi*, survey respondents  
174 advised that a next-generation test for typhoid fever should be able to detect both *S. Typhi* and *S.*  
175 *Paratyphi*.

176 The target population was identified based on published data from Africa and Asia.[25,28] Children  
 177 aged two to 14 years bear the brunt of the global typhoid burden but there is substantial variability  
 178 both within and between regions in terms of who is most affected. A recent study from Pakistan found  
 179 higher rates of typhoid fever in adults than in children.[28] These data highlight the need for a typhoid  
 180 RDT that can detect the disease in individuals of all ages, as confirmed by the Delphi survey.

181

182 When designing new diagnostic tests, the level of the healthcare system where a test will be deployed  
 183 is an important consideration. Ghani, *et al.*, have identified five healthcare system levels, with  
 184 different types of diagnostic or prognostic tools suitable for different levels.[29] Typhoid is most  
 185 prevalent in LMIC with limited healthcare resources, and in these contexts the optimal typhoid test  
 186 would not require sophisticated equipment and could be easily interpreted by non-laboratory  
 187 personnel.[6,7] Respondents agreed that a test would optimally be usable at the lowest level of a  
 188 healthcare system, which in many cases is a community health worker seeing patients in an informal  
 189 environment. However, as the current gold standard of blood culture requires laboratory equipment,  
 190 but has suboptimal sensitivity and specificity, some respondents felt it was acceptable for a typhoid  
 191 RDT to require basic laboratory facilities, with a trained laboratory technician, providing it meets all  
 192 other TPP criteria. Based on feedback from the initial round of the Delphi survey the minimum target  
 193 level was adjusted upward to a higher level of the health care system, but consensus agreement was  
 194 not achieved as some respondents felt strongly that the minimum requirement should be a test that can  
 195 be used in informal settings at the lowest level of the healthcare system.

196

197 **Table 2. Typhoid target product profile characteristics: scope of the test**

Characteristic	Minimal requirement	Optimal requirement	References
Goal	Point-of-care test to improve patient management through diagnosis and treatment of infection with acute <i>Salmonella enterica</i> serovars Typhi or Paratyphi	Combine with diagnostics for malaria and other causes of acute febrile illness as part of a treatment algorithm	[8,30]
Target population	All individuals with undifferentiated acute fever		[15,25,28]
Target user	Laboratory technician	Healthcare worker	[7]
Target level of health system*	District hospital with basic laboratory facilities	Primary health posts and centres	[6,29]

198 \* Consensus not reached among survey respondents.

199

## 200 Test performance

201 Blood culture is commonly used as the reference standard for typhoid diagnosis but requires  
 202 sophisticated equipment not readily available in LMIC where typhoid is endemic.[6] Typhoid blood  
 203 cultures require a minimum of two to 10 mL of venous blood due to the low bacterial load in  
 204 peripheral blood, and have poor sensitivity estimated at only 61% in a recent systematic review.[31]  
 205 The most commonly used typhoid POC tests (Widal, Typhidot, Tubex, Test-It Typhoid, TPTest)

206 require between 5  $\mu$ L and 1 mL of blood, but have only moderate sensitivity and specificity.[21]  
 207 Survey respondents agreed that an optimal next-generation typhoid RDT would use a capillary blood  
 208 sample with a volume of  $\leq 100$   $\mu$ L, or a less invasive sample type, excluding urine and stool[12,26].  
 209 However, survey respondents indicated that  $\leq 1$  mL of venous blood was an acceptable minimum  
 210 requirement due to the current difficulty in accurately diagnosing typhoid fever (Table 3). The TPP  
 211 allows for up to two sample processing steps as an RDT may require serum to be separated from  
 212 whole blood, with at most five steps for the test of which no more than two should be timed,[26] and a  
 213 total hands on time of less than five minutes. Based on a published expert consensus TPP for  
 214 diagnostics for acute febrile illness, RDT performance ideally would entail three or fewer steps, of  
 215 which at most one step is timed, with a total hands-on time of one minute or less.[26]

216

217 For a new typhoid diagnostic test to have the greatest impact on prescribing and clinical outcomes it  
 218 would need to yields results in less than a few hours.[32] There was consensus agreement that the  
 219 optimum requirement would make results available within 15 minutes to coincide with the average  
 220 development time of other point-of-care diagnostics commonly used in LMIC environments (for  
 221 example, malaria antigen-detecting RDTs). A minimum requirement of results within two hours was  
 222 agreed; this would be a significant improvement from the  $\geq 48$  hours required for blood culture, and  
 223 two hours was deemed the longest time that outpatients could wait for test results, particularly in rural  
 224 settings where patients may have to travel long distances to reach a health facility.[26]

225

226

227

**Table 3: Test performance characteristics for a typhoid diagnostic target product profile**

Characteristic	Minimum requirement	Optimum requirement	References
Sample type	Venous blood	Capillary blood or less invasive sample type (e.g. saliva), excluding stool and urine	[12,26]
Sample collection	Transfer and quantification device included in the test		Industry standard
Sample volume/ sample transfer device	$\leq 1$ mL venous blood	$\leq 100$ $\mu$ L capillary blood	[33]
Additional sample preparation	2 sample processing steps	None required	May need to separate serum from whole blood before applying to RDT
Ease of use	$\leq 5$ steps, of which $\leq 2$ are timed	$\leq 3$ steps, of which $\leq 1$ is timed	[6]
Total hands-on time	$\leq 5$ minutes	$\leq 1$ minute	[7,26]
Time to result	$\leq 2$ hours	$\leq 15$ minutes	[26,32]
Read out of results	Binary results		[6]
In use stability	Results stable $\geq 15$ minutes	Results stable $\geq 1$ hour	[26]
Data output and connectivity	No wireless connectivity required	Wireless connectivity used to transfer data	[34]
Data interpretation	Readout easily interpretable by non-laboratory personnel	No data interpretation required	[7]
Analyte type	Any acceptable analyte, or combination of analytes, that can meet sensitivity and specificity thresholds		[7]
Analytical sensitivity/	Limit of detection should be such that it allows clinically		[7]

Limit of detection	relevant performance as defined below		
Diagnostic sensitivity*	≥90%	≥95%	[21,35–38]
Diagnostic specificity	≥95%	≥98%	[21,35–38]
Reproducibility	Kappa ≥0.9 between different operators and laboratories/locations		[39]

228 \* Consensus not reached among survey respondents.

229

230 Researchers have proposed that an ideal typhoid diagnostic test would have a simple positive/negative  
 231 read-out similar to a home pregnancy test,[6] with results easily interpretable by non-laboratory  
 232 personnel.[7] The typhoid TPP therefore requires a binary read-out of results, with data that either do  
 233 not require interpretation, or that are easily interpretable. No specific analyte or limit of detection is  
 234 specified for the typhoid TPP, with any analyte or combination of analytes acceptable providing the  
 235 test meets all other TPP requirements.

236

237 The minimum TPP requirement for diagnostic sensitivity is ≥90%, with an optimum sensitivity of  
 238 ≥95%, based on modelling data and expert opinion.[21,35–38] Consensus agreement in the Delphi  
 239 survey was not achieved for test sensitivity, which reflects the substantial variation in published  
 240 expert opinions regarding the desirable accuracy for a typhoid RDT. However, survey respondents did  
 241 agree on a minimum specificity of 95% and an optimum specificity of 98%.

242

### 243 **Operational characteristics**

244 Survey respondents agreed on operational characteristics of the typhoid TPP (Table 4). Typhoid  
 245 diagnostic test kits ideally should consist of individually packaged tests with individual reagents (if  
 246 required) and a user manual in local languages, based on TPP characteristics for other POC tests in  
 247 regions where typhoid is endemic.[26,40,41] Up to one reagent preparation step is acceptable, to  
 248 allow for reconstitution of a powdered reagent. The test should not require a cold chain, with  
 249 operating conditions that reflect the high temperatures and humidity that are present in many regions  
 250 in Africa and Asia where typhoid is prevalent.

251

252 **Table 4: Consensus operational characteristics for the typhoid target product profile**

Characteristic	Minimum requirement	Optimum requirement	References
Kit configuration	Package of single kits sharing reagents (if required) and user manual. Instructions in English, French, Spanish and Portuguese.	Package of single kits with individual reagents (if required) sharing user manual. Instructions in local languages.	[26,40]
Reagent preparation	One reagent preparation step	None required	[26,41]
Operating conditions	- between 5 and 40°C - ≤90% relative humidity	- between 5 and 45°C - ≤90% relative humidity	[40]
Transportation and storage stability	≥ 12 months at ≤35°C and ≤70% relative humidity, no cold chain needed, ability to withstand transport stress (≤3 days at 60°C)	≥ 24 months at ≤45°C and ≤90% relative humidity, no cold chain needed, ability to withstand transport stress (≤3 days at 60°C)	[40]
Equipment	Small, portable or handheld, battery-	No equipment	[6,7]

(Instrumentation external to test)	operated instrument		
External maintenance	Minimal maintenance, simple to perform by non-laboratory personnel	No maintenance	[26]
Calibration	≤1 annual calibration, ideally auto-calibration by operator or remotely	No calibration	[26]
Internal/Process control	Included in each assay		Industry standard
Batch/Quality control	Positive and negative controls included in each kit		Industry standard
Power requirements	Battery or solar powered	No power needed	[26]
Water requirement	No external water required		[26]
Waste disposal	Biohazard waste, sharps disposal	No toxic waste requiring special disposal	[42]
Bio-safety	Basic biosafety level 1, WHO Class B In-vitro diagnostic (moderate individual and low public health risk)	Basic biosafety level 1, WHO Class A In-vitro diagnostic (low individual and low public health risk).	[42,43]
Training requirements	≤ 0.5 days for lab technician	≤ 0.5 days for experienced health worker	[6,7,21]
Cost per test	End-user cost <\$3.00 USD	End-user cost <\$1.00 USD	[7,26]

253

254 Currently most typhoid treatments are provided in outpatient settings, including informal medical  
 255 shops, so an ideal POC test would not require any sophisticated equipment or a formal laboratory  
 256 infrastructure.[7] A small, portable or handheld battery-operated instrument is acceptable,[44] but  
 257 ideally no equipment would be required. To be truly transformative, a typhoid POC test needs to be  
 258 useable in settings without a reliable power or water supply. If power is required, then it should be  
 259 provided by a combination of rechargeable batteries and solar power.

260

261 Empiric treatment of suspected typhoid cases is common, typically using relatively inexpensive  
 262 antibiotics.[7] To reduce the overuse of empiric antibiotics, the end-user cost for a typhoid POC test  
 263 was set at <\$3.00 USD (minimum requirement) or <\$1.00 USD (optimum requirement) to reflect the  
 264 cost of empiric antibiotics in endemic regions.[7] Delphi survey feedback indicated that the highest  
 265 cost to the end-user in Africa should be equivalent to one US dollar.

266

267 **DISCUSSION**

268 Typhoid diagnostic tests currently lack the sensitivity and specificity required for an accurate  
269 diagnosis at the point of care, resulting in the overuse of antibiotics through empiric treatment. The  
270 WHO has developed a list of characteristics that make a test suitable for the resource-limited settings  
271 where typhoid is prevalent: the ASSURED acronym stands for affordable, sensitive, specific, user-  
272 friendly, rapid and robust, equipment-free, and delivered to those in need.[44] TPPs build upon these  
273 criteria and increasingly are used in the global health community to guide development of diagnostic  
274 tests and to inform donors about global health priorities.[26,40,41] This TPP outlines the minimum  
275 and optimum desired characteristics for an improved typhoid RDT and is intended to accelerate  
276 development of optimized diagnostics that meet the needs of users in endemic regions.

277

278 Antibiotic resistance is a growing threat to typhoid treatment, with strains of *S. Typhi* that are resistant  
279 to three first-line agents now prevalent in parts of Asia and Africa.[8] The emergence of multi-drug  
280 resistant strains that have acquired additional resistance to fluoroquinolones and third-generation  
281 cephalosporins, known as extremely drug resistant *S. Typhi*, has left azithromycin and the costly  
282 intravenous carbapenem drugs as the only antibiotic options for some patients.[8] There have been  
283 sporadic case reports of azithromycin-resistant *S. Typhi*,[8] but if extremely drug resistant strains  
284 acquire azithromycin resistance, carbapenems could be left as the only effective treatment. To prevent  
285 the further spread of resistant *S. Typhi* it would be beneficial to conduct drug susceptibility testing for  
286 individual patients before commencing antibiotic therapy. Drug susceptibility testing was not included  
287 as a TPP requirement because it is not likely to be feasible in non-culture POC tests due to the  
288 evolving nature of typhoid resistance[8] and may make interpretation of test results too complex for  
289 users at the lowest healthcare level[29]. However, some Delphi survey respondents felt that for an  
290 RDT ever to replace blood culture it must include susceptibility testing. An RDT for diagnosis  
291 combined with epidemiological knowledge of the antibiotic sensitivity of strains, updated at intervals,  
292 could be a compromise solution.

293

294 The 2017 Global Burden of Disease study estimated that *S. Paratyphi* affected 3.4 million people  
295 annually, with 19.1 thousand deaths, compared to 10.9 million cases and 116.8 thousand deaths for *S.*  
296 *Typhi*. [2,3] The higher morbidity and mortality of *S. Typhi* makes it a greater public health concern,  
297 but the increasing prevalence of *S. Paratyphi* in certain regions makes it prudent for a next-generation  
298 test to detect *S. Paratyphi* as well as *S. Typhi*. [5,30,45] Delphi survey feedback noted that not being  
299 able to detect *S. Paratyphi* could undermine clinician confidence in a next-generation typhoid POC  
300 test as *S. Typhi* and *S. Paratyphi* may cause indistinguishable clinical syndromes.[4] As drug-resistant  
301 typhoid continues to spread, it may become necessary to differentiate between these two serovars  
302 prior to starting therapy due to different antibiotic susceptibility profiles.[46]

303

304 The minimum diagnostic requirement for a typhoid RDT in this TPP was  $\geq 90\%$  sensitivity and  $\geq 95\%$   
305 specificity, with an optimum threshold of  $\geq 95\%$  sensitivity and  $\geq 98\%$  specificity. Consensus  
306 agreement was achieved in the Delphi survey for specificity but not sensitivity, reflecting the  
307 substantial variability seen in the published literature with proposed targets ranging from 80-90% for  
308 sensitivity and 90-98% for specificity.[21,36,37] The poor sensitivity of blood culture as a reference  
309 standard for typhoid diagnosis makes it difficult to accurately assess the performance of novel  
310 diagnostic tests.[47] A composite reference standard that combines multiple tests with high specificity  
311 but suboptimal sensitivity has been proposed as a possible way to improve diagnostic accuracy.[7,47]  
312 Various test combinations have been used as a composite reference standard for typhoid,[47] but  
313 respondents in this Delphi exercise advised that the adoption of a standardized composite is required  
314 before it can be included in a TPP. A standardized composite might include tests (bone marrow  
315 culture, PCR, transcriptomics etc.) that contribute to a reference standard but are not suitable for use  
316 in regular practice.

317

318 Typhoid fever is transmitted by the faeco-oral route in water and food contaminated by *S. Typhi* in  
319 human faeces and so is endemic in low-resource environments that lack access to clean water and  
320 adequate sanitation. While improvements in the infrastructure for water, sanitation and hygiene could  
321 reduce or eliminate typhoid, these are costly long-term endeavors. The newly approved Typbar-TCV  
322 vaccine may help to reduce the global burden of enteric fever caused by *S. Typhi*,[48] but an improved  
323 diagnostic test is required to accurately estimate disease incidence and facilitate targeted vaccine  
324 deployment. To have a meaningful impact on the overuse of antibiotics that has contributed to the  
325 emergence of resistance in *S. Typhi* and other bacteria, an improved typhoid POC test needs to be  
326 used as part of a treatment algorithm in conjunction with diagnostics for malaria and other causes of  
327 acute febrile illness. The isolated use of a disease-specific diagnostic test for a febrile patient may help  
328 focus treatment if positive, but a negative test may result in alternative empiric antibiotic therapy, as  
329 seen for malaria.[24,49] Drug susceptibility testing for *S. Typhi*, performed at reference laboratories,  
330 could inform local treatment algorithms based on regional antibiotic susceptibilities.[50]

331

332 This work provides the first comprehensive TPP for a next-generation POC test for typhoid fever. The  
333 main limitations of this study were the lack of consensus agreement for all TPP characteristics, and  
334 the relatively low response rate in the second round of the Delphi survey. The length of the survey  
335 may have been a barrier to completion due to the amount of time required to provide feedback on all  
336 35 TPP characteristics. Further discussion among the typhoid community is needed to settle on the  
337 optimal target level of the health care system and the required diagnostic sensitivity. While this TPP is  
338 a first step toward improved awareness of the typhoid diagnostic needs, it is crucial to keep the  
339 conversation going and to engage global health funders, diagnostics developers, and national policy  
340 makers in the discussion on how improved diagnostic tools and related innovations can be used to

341 improve surveillance data as well as support patient management decisions in the context of universal  
342 health care.  
343

344 **ACKNOWLEDGEMENTS**

345 We thank all the participants of the 2 rounds of Delphi surveys for their invaluable contribution to  
346 shape the TPP and highlight open questions. We would further like to thank the UK aid from the  
347 British people for supporting this work.
