1 **Abstract**

2 **Background:** Contrast-induced acute kidney injury (CI-AKI) is a complication commonly
3 associated with invasive angiographic procedures and is considered the leading cause of
4 hospital-acquired acute kidney injury. CI-AKI can lead to a prolonged hospital stay, with a
5 substantial economic impact, and increased mortality. The DyeVert™ PLUS EZ system
6 (FDA approved and CE marked) is a device that has been developed to divert a portion of the
7 theoretical injected contrast media volume (CMV), reducing the overall injected contrast
8 media and aortic reflux and potentially improving long-term health outcomes.

9 **Objectives:** To assess the long-term costs and health outcomes associated with the
10 introduction of the DyeVert™ PLUS EZ system into the health care service for the
11 prevention of CI-AKI in a cohort of patients with chronic kidney disease (CKD) stage 3-4
12 undergoing Diagnostic Coronary Angiography (DAG) and/or Percutaneous Coronary
13 intervention (PCI), compared with current practice.

14 **Methods:** A de novo economic model was developed based on the current pathway of
15 managing patients undergoing DAG and/or PCI and on evidence related to the clinical
16 effectiveness of DyeVert™, in terms of its impact on relevant clinical outcomes and health
17 service resource use. Clinical data used to populate the model were derived from the
18 literature or were based on assumptions informed by expert clinical input. Costs included in
19 the model were obtained from the literature and UK-based routine sources. Probabilistic
20 distributions were assigned to the majority of model parameters so that a probabilistic
21 analysis could be undertaken, while deterministic sensitivity analyses were also carried out to
22 explore the impact of key parameter variation on the model results.

23 **Results:** Base-case results indicate that the intervention leads to cost savings (- £3,878) and
24 improved effectiveness (+ 0.02 QALYs) over the patient's lifetime, compared with current
25 practice. Output from the probabilistic analysis supports the high likelihood of the
26 intervention being cost-effective across presented willingness-to-pay (WTP) thresholds. The
27 overall long-term cost saving for the NHS associated with introduction of the intervention for
28 each cohort of patients is over £175 million. The cost savings are mainly driven by lower risk
29 of subsequent diseases and associated costs

30 **Conclusions:** Introduction of the DyeVert™ PLUS EZ system has the potential to reduce
31 costs for the health care service and lead to improved clinical outcomes for patients with
32 CKD stage 3-4 undergoing angiographic procedures.

33

34 **Key words:** Contrast-induced acute kidney injury, Diagnostic Coronary Angiography,
35 Percutaneous Coronary intervention, DyeVert™ PLUS EZ system, Economic model, Cost-
36 effectiveness analysis.

37

38 **Key Points for Decision Makers**

- 39
- 40 • An economic model has been developed to consider the cost-effectiveness of the
41 DyeVert™ PLUS EZ system for use amongst patients undergoing angiographic
42 procedures.
 - 43 • Results of the economic analysis indicate that the DyeVert™ PLUS EZ system is
highly likely to be cost saving and result in improved patient outcomes.

1

2 **1. Introduction**

3

4

One common complication associated with angiographic procedures, and attributed to radiocontrast media, is the contrast-induced acute kidney injury (CI-AKI) (1-3). CI-AKI is defined as the impairment of renal function, measured as either a 25% increase in serum creatinine (SCr) from baseline or a 0.5 mg/dL (44 µmol/L) increase in absolute SCr value within 48-72 hours after intravenous contrast administration.

5

6

7

8

9

The development of CI-AKI can lead to prolonged hospital stay, additional financial burden, and increased mortality (4, 5). In particular, the economic impact of CI-AKI in the UK is significant. It is estimated that in 2010-2011 there were 977,116 excess bed days attributable to AKI in the UK, with an associated cost of £304 million (4). CI-AKI is considered the leading cause of hospital-acquired AKI and is responsible for one third of AKI cases (6). This condition is closely related to angiographic procedures, where the incidence of CI-AKI in patients undergoing angiographic procedures ranges between 1-2% for patients without prior chronic kidney disease (CKD), and 30% for patients with a combination of risk factors (7-9).

10

11

12

13

14

15

16

17

18

Since there is no definitive treatment available for CI-AKI, the focus has been on the prevention of the condition. The European Society of Cardiology (ESC) published updated guidelines on the prevention of CI-AKI (10), providing a framework for the use of evidence-based preventative strategies. Among these strategies, they recommend the identification of patients at risk of CI-AKI, appropriate periprocedural hydration, and minimising contrast volume in at-risk patients. Previous studies have shown that the CI-AKI is associated with increased risk of death, myocardial infarction, bleeding, and recurrent renal injury after discharge (11, 12).

19

20

21

22

23

24

25

26

27

The DyeVert™ PLUS EZ system (FDA approved and CE marked) is a device that adjusts contrast media (CM) during manual injection. This is achieved by diverting a portion of the theoretical injected contrast media volume (CMV), reducing the overall injected contrast media and reducing aortic reflux (13). Reduction in CMV has been shown to be non-linearly associated with decreased risk of CI-AKI, which can be linked to a reduction in short- and long-term costs and consequences (14). This economic analysis aims to estimate the cumulative difference in costs and effectiveness in patients undergoing Diagnostic Coronary Angiography (DAG) and/or Percutaneous Coronary intervention (PCI) with the use of DyeVert™ PLUS compared to the current standard of care.

39 **2. Methods**

40

41

42

43

44

45

46

47

A de novo economic model was developed reflecting the current management pathway of patients undergoing DAG and/or PCI. The model was built upon evidence related to the clinical effectiveness of DyeVert™ PLUS, measured as the reduction in contrast media (CM) and subsequent incidence of CI-AKI, as well as economic evidence related to associated NHS resource use. For each treatment arm, costs and outcomes were aggregated on the basis of a series of decisions and events. The structure of the model remained unchanged between the two treatment options.

The model was based on a hypothetical cohort of patients with CKD stage 3-4 undergoing

Cost-utility analysis of DyeVert™ PLUS EZ system for Preventing Contrast-Induced Acute Kidney Injury

1 DAG and/or PCI. As per NICE requirements, and in order to fully capture the differences in
2 costs and benefits between the DyeVert™ PLUS EZ system and the comparator, a lifetime
3 time horizon was used in the base-case analysis (15). The recommended discount rate in the
4 UK (3.5% per annum) was applied for both costs and benefits (16). The model considered
5 all costs from the UK NHS and personal social services perspective, and was developed in
6 Microsoft Excel.
7
8

9 **2.1 Model structure**

10 The model structure comprises a decision tree followed by a Markov model with six health
11 states. This model has a lifetime time-horizon with costs and benefits estimated in the
12 decision tree for the first three months, and in the Markov model for the remainder of the
13 patient's lifetime. The Markov model has a cycle length of three months. Figure 1 presents an
14 illustrative representation of the model structure. The model was used to simulate the
15 management of patients undergoing DAG and/or PCI with reduced kidney function (i.e.
16 eGFR 15 - 60 ml/min/1.73m²). In each strategy, patients may or may not experience a CI-
17 AKI requiring further treatment. Patients may then either remain in state 'CKD stage 3-4' (or
18 state 'CKD stage 3-4 (AKI history)' if they previously had CI-AKI) or progress according to
19 the natural progression of CKD to state 'CKD stage 5'. Patients whose renal insufficiency is
20 not severe (i.e. 'CKD stage 3-4') can experience a recurrent AKI or a myocardial infarction
21 (MI) at any point. Patients who enter the 'CKD stage 5' are assumed to either remain in this
22 state or die, as they will be receiving dialysis and treatments to prevent an MI. Patients in
23 each model state will incur associated costs and quality-adjusted life-years (QALYs).
24

25 Simulated patients are at risk of death from all causes during any given cycle period. Risk of
26 death is conditional on CKD stage, history of AKI and/or MI, and age. The all-cause
27 mortality rates were derived from general population mortality statistics reported in national
28 life tables (17) and were adjusted to reflect the extra mortality associated with CI-AKI and
29 renal insufficiency.
30

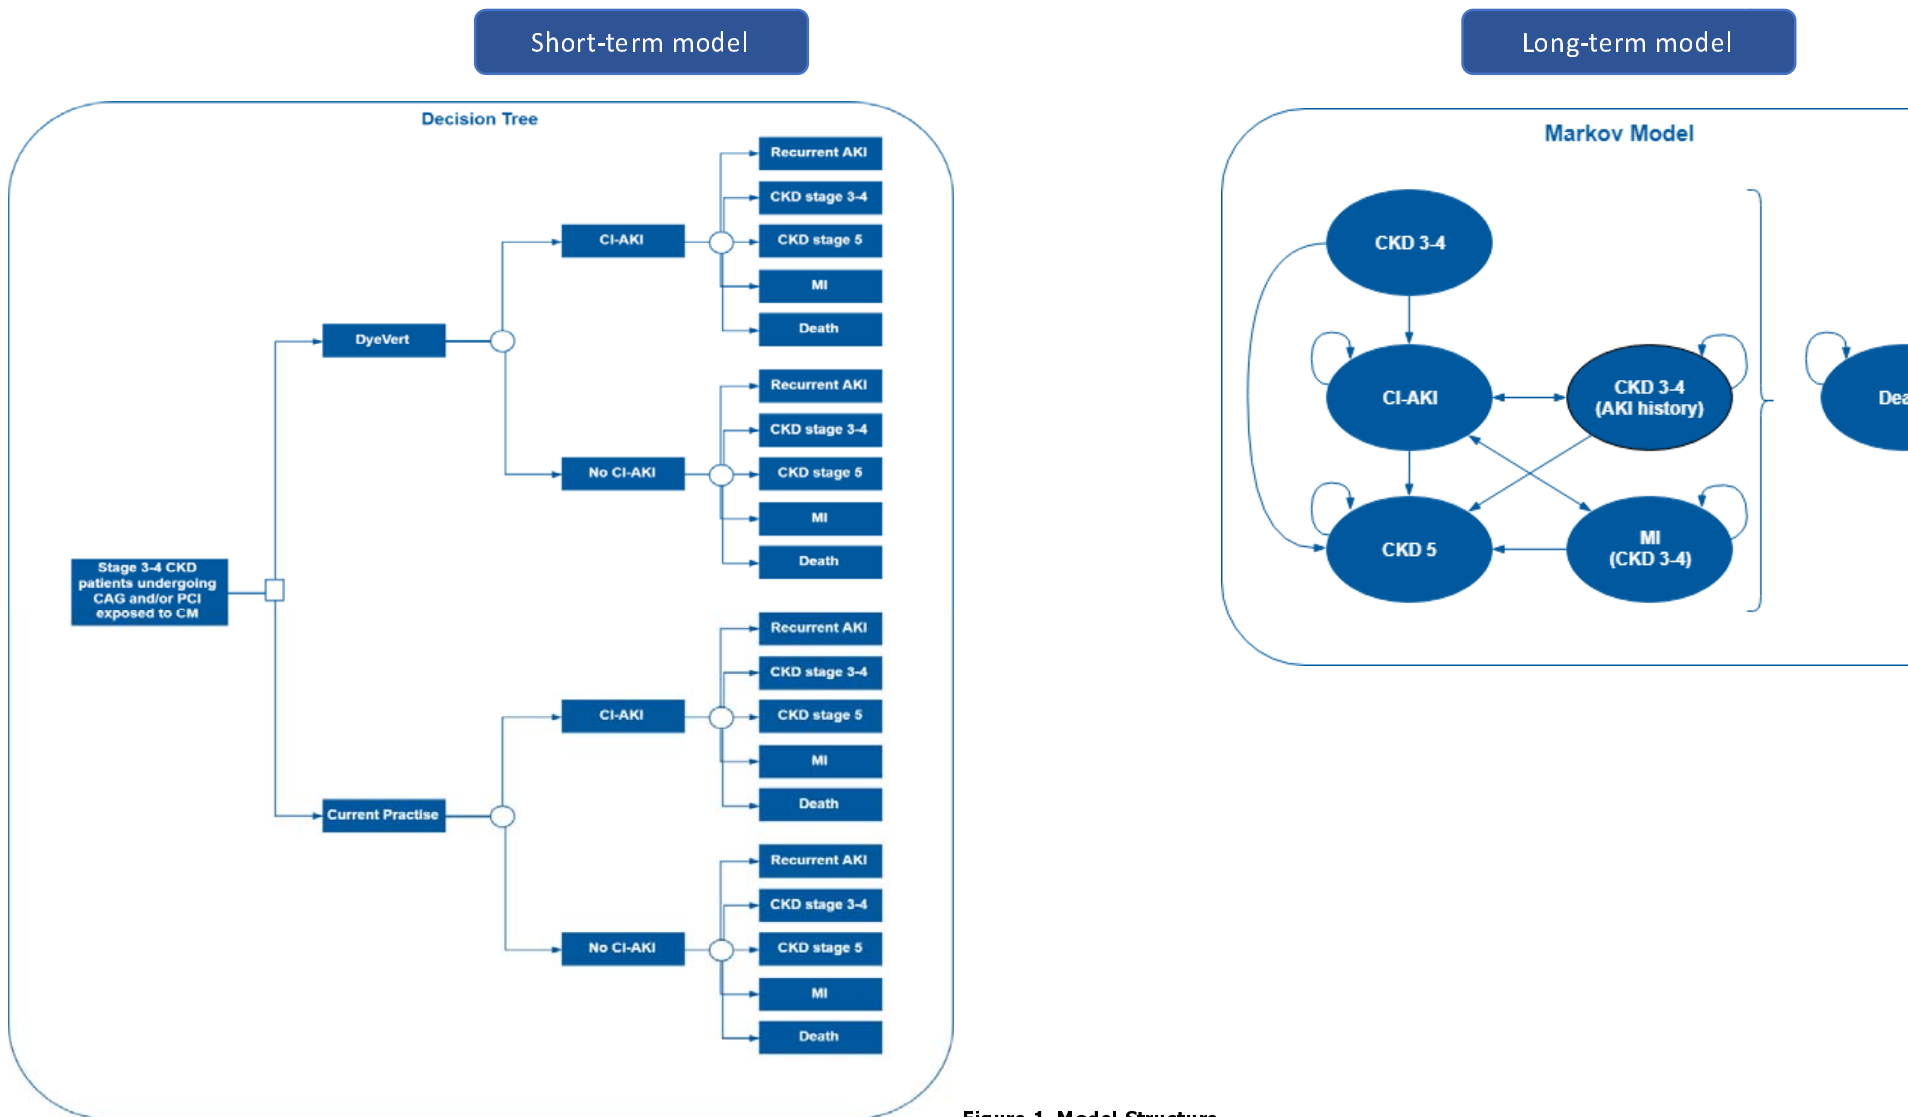

Figure 1. Model Structure

2.2 Model inputs

All inputs used to populate the economic model are described in the following section and are presented in Table 2. Patients at model entry was those undergoing DAG and/or PCI with some kidney function impairment (CKD stage 3-4). The base-case population was 72 years old (14). The number of patients undergoing DAG and/or PCI was derived from NHS reference costs activity of percutaneous coronary angioplasty (HRG code EY40-EY41) and cardiac catheterisation (HRG code EY42-EY43) (18). It was assumed, based on Gurm et al. (14) that 26% of these procedures would be DAG combined with PCI.

Clinical effectiveness

Evidence has shown that when DyeVert™ PLUS is used in patients undergoing DAG and/or PCI the contrast media volume is significantly reduced (14). To estimate the reduction in risk of CI-AKI after using DyeVert™, we analyzed the CI-AKI rate based on the 0.5 serum creatinine increase definition used in the development of the Mehran (9) risk score and ran the Mehran risk score on the population to arrive at a projected risk rate for the population. The projected rate was 14% and the actual rate was 11%. Therefore, the estimated risk reduction was estimated to be 21.4%. The estimated risk reduction was used to adjust the risk of CI-AKI in the intervention arm for the base-case analysis. Alternatively, the risk reduction was estimated using the data from Gurm et al., 2016 and Gurm et al., 2018 (14, 19) (Table 1 below).

Table 1 Effectiveness of DyeVert™ PLUS

Effectiveness	Value (SD)	Source
% Contrast volume reduction per procedure (DyeVert™)	40.1% (8.8)	(14)
% Reduction in Risk of CI-AKI associated with 40.1% reduction in contrast media for patients with eGFR ≤ 60 ml/min/1.73m ²	15.1%	(19)

Transition probabilities

The incidence of CI-AKI in patients with CKD undergoing PCI was based on a cohort study of 1,473 patients and was estimated to be 30% (3, 9). The baseline transition probability associated with the progression of patients from CKD stage 3-4 to CKD stage 5 for different age groups, was based on a ten-year cumulative incidence rate in a cohort study of 3,047 patients (20). The probability of transitioning to Stage 5 CKD following a CI-AKI after the first cycle (first 3 months) was obtained from clinical guidelines from CG169 and James et al., 2010 (21) and from the study by Valle et al., 2017 (12). The probability of MI for patients with a history of CI-AKI was taken from Valle et al., 2017 (12). For patients who had not experienced an AKI throughout the model, the probability of MI was 1.42% and 0.688% in the first 3 months and the subsequent cycles respectively (12). For patients who had experienced CI-AKI in the previous cycles, the equivalent probabilities were 2.581% and 1.291% respectively (12).

The probability of recurrent AKI was taken from the same study as the probability of MI (12). Based on the cumulative incidence in the 3rd month and the first year of the study follow-up, we estimated the probability of recurrent AKI in the first 3 months after the DAG and/or PCI, and for subsequent 3-month cycles. For patients who had not experienced a CI-

Cost-utility analysis of DyeVert™ PLUS EZ system for Preventing Contrast-Induced Acute Kidney Injury

1 AKI after the procedure, the probability of recurrent AKI was 1.78% and 0.911% in the first
 2 3 months and the subsequent cycles respectively. For patients who had experienced CI-AKI
 3 during the procedure, the equivalent probabilities were 6.83% and 2.431% respectively.
 4

5 **Probability of death**
 6

7 Standardised mortality ratios for each health state included in the model were applied to the
 8 relevant age-dependent mortality rates and are shown in Table 2 below. These mortality
 9 ratios were derived from the literature.

10 **Table 2 Main inputs used in the model**

Parameters	Mean	Distribution	Lower limit	Upper limit	Source

Cost-utility analysis of DyeVert™ PLUS EZ system for Preventing Contrast-Induced Acute Kidney Injury

1 **Costs**

2 **Resource consequences**

3 Unit costs for all resource use estimates were extracted from the literature or obtained
4 through other relevant sources such as NHS reference costs (22), Personal Social Services
5 Research Unit (31), British national Formulary and manufacturer price list (32). Costs were
6 measured in Sterling (£) for the year 2018 and were discounted at 3.5% per annum, where
7 appropriate. All costs included in the model are shown in Table 2.

8 The choice of cost items was mainly informed by a NICE clinical guidelines model
9 developed for the evaluation of prevention strategies of CI-AKI using different hydration
10 methods (33). However, updated unit costs and dosages of drugs were extracted from the
11 literature. In the instances where unit costs of relevant outcomes were not available, the cost
12 of items used in the NICE guidelines model (CG169 (24)) were inflated to reflect current
13 prices. This was done by applying an inflation index provided by the National bank of
14 England (34).

15

16 **Intervention cost**

17 The cost of DyeVert™ PLUS technology was estimated to be £350, including the cost of the
18 smart syringe and module. The company has indicated that free training for using the
19 technology will be provided to clinical staff, and a smart monitor will be provided free of
20 charge. Therefore, these costs were not taken into account.

21

22 **CI –AKI costs**

23 For the estimation of CI-AKI event costs, two different methods were used in the model: (1)
24 For patients who have to be re-admitted to the hospital due to CI-AKI after a DAG and/or
25 PCI procedure, the cost of an index admission due to AKI was used. (2) For patients admitted
26 for DAG and/or PCI who have a prolonged length of stay due to CI-AKI, the cost of these
27 additional bed days was considered.

28 **Health state costs**

29 Patients in CKD stage 3-4 are expected to incur costs associated with consultations with the
30 nephrologist (33), combined with lab resource costs and an assumed 5-minute phlebotomist
31 time to measure the patient's eGFR. Additional costs would include 9% of patients requiring
32 Epoetin-alfa to treat anaemia, as recommended by the clinical guidelines for anaemia
33 treatment in patients with CKD (33). Epoetin-alfa dosage was estimated for a 77kg individual
34 on average, according to ONS. To take into consideration the patients who require diuretics,
35 an assumption was made based on the guidelines model (33) that about a quarter of patients
36 (26%) in the CKD 3-4 stage were in CKD stage 4, 60% of whom would be on a 40mg daily
37 dose of Furosemide (24). The total cost of CKD stage 3-4 per cycle was estimated to be
38 £269.50.

39

40 Patients in stage 5 CKD will incur the drug costs. However, patients in this stage will also
41 incur costs associated with Renal Replacement Therapy (RRT) or Conservative Management.
42 In this stage, patients are expected to incur costs such as RRT procedures, anaemia
43 management, specialist appointments, EGFR measurements and diuretics. In the first cycle
44 that a patient enters the CKD stage 5 state, it is assumed that the intensity of treatment will be
45 increased compared to later stages, as costs of initiating treatment are captured. It was

Cost-utility analysis of DyeVert™ PLUS EZ system for Preventing Contrast-Induced Acute Kidney Injury

1 assumed, based on the NICE guidelines model (24), that 90% of patients would receive RRT
2 in this model state. For the estimation of RRT costs, a pooled average was taken from NHS
3 reference costs 2017-18 accounting for national usage of different treatment modalities, such
4 as haemodialysis and filtration (22). Patients entering the CKD stage 5 will receive an access
5 procedure, which will then allow for permanent access for RRT. In subsequent cycles, it was
6 assumed that there would be no further access procedure-related costs. Drugs and check-ups
7 are also required and are more frequent in 'CKD stage 5'. It was assumed that all patients in
8 this stage would have an eGFR more frequently (on a weekly basis), and two nephrologist
9 appointments per three months. In this state, Epoetin was assumed to be administered to 33%
10 of the patients in the same dosage as for patients in CKD 3-4 stages (33). Patients on
11 conservative management (10%) will be receiving monthly home visits by a specialist nurse
12 as well as telephone calls on a weekly basis. It was assumed (33) that diuretics would be used
13 by 90% of the patients with a double dosage compared to CKD 3-4 stages (80mg). The cost
14 of AMI was taken from Walker et al., 2016 (27). In this study, the cost of AMI for the 1st
15 year was estimated to be £6,869 and £1,780 for subsequent years. These costs were inflated
16 to represent prices in 2018.
17

18 Utilities

19 Utilities for CKD stages were obtained from a Japanese study (28) used in both the NICE
20 guidelines (CG169) (24, 33) and an NHS report on kidney care (35). An adjustment for the
21 UK population was made by multiplying the values with the general UK population average
22 utility values for people aged 65 to 75. For the stage of CI-AKI, utility values were taken
23 from Sullivan et al., 2011 (30) who reported in a catalogue of UK EQ-5D derived utilities a
24 0.525 (n=194) utility value associated with kidney injury ('renal failure'). For the MI state,
25 the same utility as in CKD 3-4 was assumed.
26

27 3. Analysis

28 A Monte Carlo simulation was conducted (10,000 iterations) to derive cumulative estimates
29 of costs and effects for each strategy in the model. Probabilistic distributions were assigned to
30 the majority of model parameters (Table 2) so that a probabilistic analysis could be
31 undertaken, while deterministic sensitivity analyses were also carried out to explore the
32 impact of key parameter variation on the model results. Total cost savings for the entire
33 cohort of patients receiving the intervention in the UK over a lifetime time horizon were also
34 calculated.

Cost-utility analysis of DyeVert™ PLUS EZ system for Preventing Contrast-Induced Acute Kidney Injury

1
2
3

4 **4. Results**

5 This section presents the results of the economic analysis; base-case results are presented first
6 followed by results of the sensitivity analysis.

7
8 **Base-case analysis**

9
10 Results of the base-case analysis presented in Table 3 indicate that the introduction of
11 DyeVert™ PLUS EZ system leads to cost savings of £3,878 per patient over a lifetime time
12 horizon. Additionally, the intervention leads to improved effectiveness over the patient's
13 lifetime (+0.02). Therefore, DyeVert™ PLUS is considered a dominant strategy (less costly
14 and more effective) compared to current practice.

15
16 The scatter plot produced from the probabilistic analysis (Figure 2) shows that the vast
17 majority of points from the 10,000 iterations of the model are in the South-East quadrant of
18 the cost-effectiveness plane (less costly and more effective), while all simulations indicate
19 that the intervention is less costly than the comparator. Additionally, the cost-effectiveness
20 acceptability curve (CEAC) shown in Figure 3 (displaying the probability that the
21 intervention is cost-effective across a range of willingness-to-pay (WTP) thresholds)
22 indicates that the DyeVert™ PLUS EZ system has a 100% probability of being cost-effective
23 across all WTP thresholds presented. The overall long-term cost savings for the NHS for
24 cohort of patients is over £175 million (Table 4). Total cost savings are calculated based on
25 the total number of patients receiving the intervention in the UK over a lifetime time horizon.
26 The cost savings are mainly driven by lower risk of subsequent diseases and associated costs.

27 **Table 3 Base-case probabilistic results**

Base-case probabilistic results	Current Practice	DyeVert™ PLUS
Cost (£)	£24,507	20,630
Incremental cost (£)	-£3,878	
QALYs	4.54	4.56
Incremental QALYs	+0.02	
ICER (£) (Δ Cost/ Δ QALYs)	DyeVert™ PLUS Dominant	
Probability of being cost-effective at £20,000 WTP threshold	100%	
Probability of being cost saving	100%

7 ***Sensitivity analysis***

8

9 A number of model parameters were also varied in sensitivity analysis. Multiple one-way
10 sensitivity analyses were carried out to explore the impact of increasing/decreasing relevant
11 parameter values by 25%. Figure 2 presents the impact of varying each parameter value by
12 25% on the incremental cost of the intervention, compared to current practice. Parameters are
13 displayed in order, with those which have the greatest impact on incremental cost at the top
14 and those which have the least impact at the end. In the base-case analysis, the incremental
15 cost of the DyeVert™ PLUS EZ system was -£3,878. As seen in Figure 2 below, MI costs (in
16 first and subsequent cycles) have the greatest impact on the incremental cost of the
17 intervention (-/+ 12.3%). When this cost is decreased, cost savings of the intervention reduce
18 and when this cost is increased, cost savings increase also. However, in both cases,
19 DyeVert™ PLUS is still a cost saving strategy. All other parameters have minimal impact on
20 the incremental costs.

5. Discussion

This study provides an insight into the potential cost savings that could be made by introducing the DyeVert™ PLUS EZ system into the UK health care system for use amongst patients with CKD stage 3-4 undergoing DAG and/or PCI. CI-AKI is one of the most common forms of AKI. The technology being evaluated is a device which acts by reducing the CMV, which has been shown to be linked to this specific form of the condition. The clinical efficacy of the technology has been demonstrated in previous clinical studies (13, 23, 36). Therefore, this innovative device has the potential to improve short-term health outcomes, and lead to cost savings and improved clinical outcomes in the longer-term. In order to assess costs and outcomes over the patient lifetime, a decision-analytic model was developed.

Results of the analysis presented here show the high likelihood that the DyeVert™ PLUS EZ system will be cost-effective over the lifetime of the patient. The probabilistic results were conclusive in that the device had a 100% probability of being cost-effective following 10,000 iterations of the model in a Monte Carlo simulation. Similarly, results of the deterministic sensitivity analyses indicated that the intervention would still be cost saving, and result in a positive net monetary benefit, in all scenarios assessed. Cost savings associated with introduction of the intervention are primarily related to the impact it has on the occurrence of AKI. Not only are there immediate cost savings associated with reducing the likelihood of experiencing an AKI, but there are also longer-term savings due to the relationship between AKI and development of CKD. See et al., 2018 (5) found that individuals who experienced AKI were at a heightened risk of experiencing new or progressive CKD. These long-term cost savings are captured in the model.

The number of studies that have been conducted to assess the relative cost-effectiveness of interventions to prevent onset of CI-AKI are limited. The National Clinical Guidelines Centre UK developed a Markov model in 2013, as part of their guidelines on AKI (24), to assess the cost-effectiveness of various different intravenous fluids for the prevention of the condition. Results of this study indicated that the most cost-effective strategy involved infusion with sodium chloride 0.9% and treatment with N-Acetylcysteine. Additionally, a study by Hiremath et al., 2018 (37) was identified which focussed on assessing the cost-effectiveness

Cost-utility analysis of DyeVert™ PLUS EZ system for Preventing Contrast-Induced Acute Kidney Injury

1 of utilising an iso-osmolar agent, iodixanol, compared to a low-osmolar contrast agent.
2 Results of this study indicated that the iso-osmolar agent dominated the low-osmolar agent,
3 i.e. was less costly and more effective over the patient's lifetime. However, no economic
4 evaluations focussing on the cost-effectiveness of interventions designed to divert an amount
5 of the injected CMV were identified, which makes the study presented here unique.
6

7 There are limitations to the analysis presented. A number of assumptions were made in
8 populating the model due to lack of appropriate data. Firstly, it was unknown how different
9 the risk of developing CI-AKI would be depending on whether the patient had received
10 DAG, PCI or a combination of both. Therefore, in the model it was assumed that this risk
11 would be the same, regardless of which of the interventions was initially received. This may
12 have the effect of over- or under-estimating the risk of developing this complication,
13 depending on which initial intervention is received, and the direction of this effect is
14 unknown. Secondly, there were no data to inform the utility value of patients with CKD stage
15 3-4 who have experienced a MI. Therefore, for the purpose of this analysis, it was assumed
16 that the utility value of these patients would be same as the utility value of patients with CKD
17 stage 3-4 who have not experienced this adverse event. Although the data used to inform the
18 effectiveness of the DyeVert™ PLUS EZ system were derived from robust, published
19 clinical evidence, the number of studies available to inform the clinical effectiveness of the
20 device were limited. Ideally, when modelling the impact of a healthcare technology on
21 clinical outcomes, multiple data sources would be available to verify the clinical efficacy data
22 being used, and that was not the case for this analysis. Finally, although evidence exists on
23 the relationship between AKI and long-term clinical outcomes (5, 12), information is limited
24 which means there is also a degree of uncertainty around the relevant data included in the
25 model. However an extreme sensitivity analysis was performed to address this limitation and
26 the main input parameters were changed by $\pm 100\%$ but the conclusion remained stable.
27 Additional minor assumptions were made in populating the model but none of these were
28 likely to have a major impact on the final model results.
29

30 Despite the limitations highlighted above, a robust decision-analytic model was developed.
31 The model was informed by clinical guidelines, published literature and expert clinical input,
32 and any assumptions that were made in this analysis can be rectified by using more robust
33 data in later studies, as a model now exists for re-analysis once additional information
34 becomes available.
35
36

37 6. Conclusion

38 The economic analysis presented in this study has shown that introduction of the DyeVert™
39 PLUS EZ system has the potential to reduce costs for the UK health care service, and lead to
40 improved quality of life and clinical outcomes for patients with CKD stage 3-4 undergoing
41 angiographic procedures.
