13 **Financial support and acknowledgments:** This research was supported by grant
14 P30ES023515, U2CES026444, UH3OD023337-03 of the National Institute of Environmental
15 Health Sciences of the National Institutes of Health. The authors would like to thank Dr.
16 Christine Schubert Kabban for helpful comments.

17

18 **Data and code sharing:** Data are available on the Centers for Disease Control and Prevention
19 (CDC)'s website (National Health and Nutrition Examination Survey cycle 2013-2014). Code for
20 the statistical method and toy examples is available in the "BWQS" R-package.

21

22 **Abstract**

23 **Background:** Per- and poly-fluoroalkyl substances (PFAS) are chemicals, detected in 95% of
24 Americans, that induce osteotoxicity and modulate hormones thereby influencing bone health.
25 Previous studies found associations between individual PFAS and bone mineral density but did
26 not analyze their combined effects.

27 **Objective:** To extend weighted quantile sum (WQS) regression to a Bayesian framework
28 (BWQS) and determine the association between a mixture of serum PFAS and mineral density
29 in lumbar spine, total and neck femur in 499 adults from the 2013–2014 National Health and
30 Nutrition Examination Survey (NHANES).

31 **Methods:** We used BWQS to assess the combined association of nine PFAS, as a mixture, with
32 bone mineral density in adults. As secondary analyses, we focused on vulnerable populations
33 (men over 50 years and postmenopausal women). Analyses were weighted according to
34 NHANES weights and were adjusted for socio-demographic factors. Sensitivity analyses
35 included bone mineral density associations with individual compounds and results from WQS
36 regressions.

37 **Results:** The mean age was 55 years old (Standard Error [SE]=1) with average spine, total and
38 neck femur mineral densities of 1.01 (SE=0.01), 0.95 (SE=0.01), and 0.78 (SE=0.01) gm/cm²,
39 respectively. PFAS mixture levels showed no evidence of association with mineral density
40 (spine: $\beta=-0.004$; 95% credible interval [CrI]=-0.04, 0.04; total femur: $\beta=0.002$; 95%CrI=-0.04,
41 0.05; femur neck: $\beta=0.005$; 95%CrI=-0.03, 0.04) in the overall population. Results were also null
42 in vulnerable populations. Findings were consistent across sensitivity analyses.

43 **Conclusions:** We introduced a Bayesian extension of WQS and found no evidence of the
44 association between PFAS mixture and bone mineral density.

45

50 Introduction

51 As the population ages, low bone mineral density has emerged as a public health concern
52 because it is related to fractures, morbidities, hospitalizations, and premature mortality.^{1,2}
53 Deterioration of bone mass differs between the sexes, with a higher prevalence in women.
54 About 10% of women over 50 years of age suffer from low bone mineral density, but only 2%
55 of men of the same age have similar bone deterioration.³ Traditional risk factors associated with
56 decreased bone mineral density include chronological age, family history of bone disease,
57 suboptimal high-impact physical activity, and smoking.⁴ However, recent evidence suggests that
58 environmental exposures, including air pollution, lead, cadmium, and mercury, are associated
59 with lower bone mineral density and higher risks for osteoporosis.⁵⁻⁷

60

61 Per- and poly-fluoroalkyl substances (PFAS) are synthetic organic chemicals that have been
62 used extensively in industrial processes and commercial applications since the 1950s. These
63 chemicals are widely used and persist for long periods of time, resulting in increased levels of
64 environmental contamination.^{8,9} The primary sources of human PFAS exposure include
65 migration from food packaging and cookware, drinking water, indoor air, and house dust.¹⁰
66 PFAS have been detected *in vivo* in human tissue samples,^{11,12} in 95% of the U.S.
67 population.¹³ PFAS are poorly metabolized and excreted slowly from the human body, with half-
68 lives of 4–8 years.¹⁴ Previous human and animal studies showed that PFAS bioaccumulate in
69 bones, with perfluorooctanoate (PFOA) being predominant.^{15,16} Due to their limited susceptibility
70 to degradation and slow elimination by human bodies, human exposure to PFAS is of increasing
71 concern.^{17,18}

72

73 The toxicity of PFAS to bones has been reported in human and animal studies, with high PFAS
74 concentrations associated with adverse skeletal outcomes, suggesting that bones are target
75 tissues for PFAS toxicity.¹⁹ PFAS are also endocrine-disrupting chemicals²⁰ based on their
76 hormonal modulation.²¹ PFAS have been suggested to impact bone density via sex
77 hormones.^{22,23} In rodents, exposure to PFAS was negatively associated with bone structure and
78 biomechanical properties.²⁴ Bone cell cultures showed increased bone resorption activity at low,
79 albeit environmentally relevant, PFAS concentrations in human bone marrow and peripheral
80 blood-derived osteoclasts, through the effect of PFAS on the cytokine and clastokine profiles
81 during cell differentiation.¹⁹ In human studies, bone PFAS concentrations and relative bone
82 volume have been correlated, but results are still inconclusive. In a few cross-sectional studies,
83 serum levels of a few PFAS were negatively associated with bone mineral density only in

84 women,^{19,21} but findings for most compounds are null in the general U.S. population.^{19,21} In
85 addition, all previous studies focused on the association between individual PFAS and bone
86 health outcomes; however, given their ubiquity and persistence, exposure likely occurs to many
87 PFAS simultaneously. Those studies failed to account for the correlation structure among PFAS
88 or to consider PFAS exposure as a mixture.

89
90 Environmental health studies have applied weighted quantile sum (WQS) regression to assess
91 the mixture effect of multiple co-occurring factors and to identify the driving factors in the
92 mixture. Briefly, the WQS regression summarizes the overall exposure to the mixture by
93 estimating a single weighted index and accounts for the individual contribution of each
94 component of the mixture by using weights.^{25,26} WQS regression splits the dataset into two
95 subsets, a training set (generally 40%) and a validation set (60%). In the first set, this approach
96 estimates the weights using an ensemble step and estimates average weights across B
97 bootstrap samples, and in the second subset it estimates the coefficient mapped to the mixture,
98 conditionally to the estimated weights.²⁵⁻²⁷ This regression also requires a priori selection of the
99 directionality (positive or negative) of the coefficient associated with the mixture, and it
100 conditions on the weights in the weighted index for testing for significance using the hold out
101 validation set. As such, it does not provide diagnostics (confidence intervals, standard deviation,
102 and p values) about the weights of the components of the mixture.^{25,26}

103
104 Here we proposed a novel Bayesian extension of the WQS regression (BWQS) to overcome its
105 limitations and to illustrate the method for assessing the combined association of several forms
106 of serum PFAS as a mixture with bone mineral density in 499 U.S. adults from the 2013–2014
107 cycle of the National Health and Nutrition Examination Survey (NHANES).^{3,28} We also stratified
108 our analysis for two vulnerable populations, men over 50 years of age and postmenopausal
109 women.

110

111 **Methods**

112 **Study population**

113 The NHANES is an ongoing survey of the noninstitutionalized U.S. adult population designed to
114 assess their health and nutritional status.²⁸ After providing informed consent, participants visited
115 a mobile examination center for standardized physical examination and collection of biological
116 specimens, which were used to assess exposure to environmental chemicals. All study
117 protocols were approved by the National Center for Health Statistics research ethics review

118 board ^{3,28}. In our analyses, we included the 2013–2014 NHANES cycle, in which both bone
119 mineral density and serum PFAS concentrations were measured and had not been previously
120 studied. The 2013–2014 cycle also included four (linear and branched) PFAS isomers that were
121 not measured in any previous NHANES cycles. For both evaluations, the selection of NHANES
122 participants was random and designed to maintain the original NHANES characteristics, as
123 previously described.^{13,29} We excluded NHANES participants with missing information about
124 bone mineral measurements (N = 7060) or serum concentrations of PFAS (N = 1450) and those
125 with missing information on covariates (smoking and physical activity) or with bilateral
126 oophorectomy (N = 74). A total of 499 adults (≥40 years) was included in the main analysis.
127 Secondary analyses were performed on 115 men over 50 years and 117 postmenopausal
128 women. Postmenopausal women included women over 60 years old, women who had not had a
129 menstrual period in the previous 12 months. We excluded from the analysis postmenopausal
130 women using hormone replacement treatment or taking parathyroid medication (N=45), due to
131 their influence on the endocrine system (**Figure 1**).

132

133 **Bone mineral density assessment**

134 Bone mineral density (g/cm²) was measured using dual X-ray absorptiometry (Hologic QDR
135 4500A fan-beam densitometers; Hologic Inc., Bedford, MA, USA).³ Antero-posterior lumbar
136 spine mineral density was scanned, and mean density was computed for the first through fourth
137 lumbar vertebrae. For the total and neck femur mineral density, the left hip was routinely
138 scanned. If a left-hip replacement or metal objects in the left leg were reported, the right hip was
139 scanned. Participants were excluded from the femur scan if they had bilateral hip fractures,
140 bilateral hip replacements, or pins. Participants weighing > 300 lbs (136 kg) or pregnant women
141 (defined by self-report or positive urine pregnancy test) were ineligible for the examination.
142 Femur neck has been proposed as the reference skeletal site for defining osteoporosis in
143 epidemiologic studies,³⁰ whereas the total femur had been used as a benchmark for
144 osteoporosis in the national Healthy People program ³⁰. Each subject's scan was reviewed in
145 the Department of Radiology, University of California, using standard radiologic techniques and
146 NHANES protocols.³

147

148 **Serum PFAS measurements**

149 Analysis of 12 PFAS in serum was conducted at the National Center for Environmental Health in
150 a random one-third subsample of nonfasting participants; the NHANES characteristic
151 proportions were maintained.^{13,29} Briefly, serum PFAS were measured using automated solid-

152 phase extraction coupled to isotope-dilution high-performance liquid chromatography– tandem
153 mass spectrometry.¹³ The complete list of PFAS with their acronyms is included in [Table S1](#). In
154 our analyses, we excluded four PFAS because their concentrations were below the limit of
155 detection for more than 60% of samples ([Table S1](#)). For the remaining PFAS, when
156 concentrations were less than the limit of detection, a value equal to the limit of detection
157 divided by the square root of two was used in the analyses.

158

159 **Statistical methods and analyses**

160 *The Bayesian WQS (BQWS) regression*

161 Let the values for the correlated mixture components C be scored into quantiles (q_{ji}) for the j-th
162 component ($j = 1, \dots, C$) and the i-th ($i = 1, \dots, N$) participant. We modeled the association between
163 the overall mixture and the outcome y_i using a generalized linear model framework

$$164 \quad g(\mu_i) = \beta_0 + \beta_1 [\sum_{j=1}^C w_j q_{ji}] + \boldsymbol{\gamma} \mathbf{Z}$$

165 where $\mu_i = E(y_i)$, β_0 is the intercept, and β_1 is the coefficient mapped to the weighted index
166 ($\sum_{j=1}^C w_j q_{ji}$); $g(\cdot)$ is link function; and $\boldsymbol{\gamma}$ is a vector of K coefficients mapped to the matrix of K
167 covariates \mathbf{Z} . Similar to WQS regression, we modeled the weight w_j for exposure to the j-th
168 component as an arbitrary function, taking values between 0 and 1, and the sum of all mixture
169 weights to be equal to 1.

170

171 The BWQS required specification of the link function, similar to the frequentist approach, and
172 prior probability distributions on all parameters, which differs from WQS regression. The general
173 assumption for each parameter was a weak or uninformative prior. However, more informative
174 priors can be chosen when prior information is known. The link function assumed the following
175 forms:

176 a) logit link function: $y_i \sim \text{binomial}(1, \mu_i)$, when Y was binary;

177 b) identity link function: $y_i \sim \text{Normal}(\mu_i, \sigma^2)$, with a noninformative prior for

178 $\sigma^2 \sim \text{IGamma}(0.1, 0.1)$, when Y was continuous.

179 Priors for the coefficients were uninformative or weakly informative and were summarized by
180 normal distributions with large variance [$\beta_0, \beta_1 \sim \text{Normal}(0, 100)$; $\boldsymbol{\gamma}_k \sim \text{Normal}(0, 100)$] for each $k =$
181 $1, \dots, K$. Priors for the weights were modelled as a unit-simplex in order to have non-negative
182 weights ($w_j \in (0, 1)$) and to sum all weights to one ($\sum w_j = 1$). The natural choice was the Dirichlet
183 distribution with the same density on each vertex for each component of the mixture; i.e., $\mathbf{w} =$
184 $(w_1, \dots, w_C) \sim \text{Dirichlet}(\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_C))$. The $\boldsymbol{\alpha}$ parameter can be selected a priori equal to $\mathbf{1}$, when
185 investigating the entire domain of the distribution uniformly. Results on simulated datasets,

186 showing the accuracy of the estimates of BWQS, are included in the supplemental material
187 (Figures S3-S5).

188

189 *Statistical Analysis*

190 We estimated the correlations among PFAS and then performed BWQS regression in which
191 bone mineral density (continuous)—in lumbar spine, total femur, and femur neck—was
192 associated with mixtures of PFAS. All analyses were adjusted for race/ethnicity (white, black,
193 Hispanic and other races), age (continuous), sex, physical activity (low-moderate or high),
194 poverty-income ratio (continuous), and smoking status (never or ever smoked). All variables
195 were selected based on previous association with the outcome.^{6,7,22} Priors for all coefficients
196 were uninformative: Normal(0,100). Secondary analyses focused on two vulnerable
197 populations—men over 50 years old and postmenopausal women.

198

199 As sensitivity analyses, we assessed the associations between the PFAS mixture and mineral
200 density in lumbar spine, total femur, and femur neck by using the frequentist WQS regression,
201 for the overall population. We also used Bayesian linear regression to determine the association
202 of each PFAS compound with bone mineral density in the overall population. We used R version
203 3.5.1 for all analyses. All analyses were weighted according to the NHANES weights,
204 appropriately rescaled for the selected subsample, as described on the Centers for Disease
205 Control and Prevention website and in previous studies.^{31,32}

206

207 **Results**

208 *Study Population Characteristics*

209 Adults included in our main analysis were 55 years old on average (standard error (SE): 0.6),
210 mostly Caucasian (49%), never smoked (60%), reported physical activity below the optimal level
211 (66%), and had an average poverty-income ratio of 2.9 (standard error (SE): 0.9) (Table 1). On
212 average, spine and (total and neck) femur mineral densities were 1.01 (SE: 0.01), 0.95
213 (SE:0.01), and 0.78 (SE:0.01) g/cm², respectively, in the adult population. Bone mineral density
214 was different by sex, with postmenopausal women having lower density (p<0.05). In all groups,
215 serum concentrations of the linear and branched PFAS isomers (NPFOS, NPFOA, and
216 MPFOS) were higher than all other PFAS levels (PFHS, PFNA, PFDE, MPAH, and PFUA)
217 (Table 1). All serum PFAS concentrations were positively correlated with each other and
218 showed similar patterns across populations (Figure 2).

219

220 *BWQS regression characteristics*

221 We employed BWQS regression to identify the association between the mixture of PFAS in
222 subjects' serum and bone mineral density in spine, total and neck femur, in all adults together
223 and in the most vulnerable populations separately.

224
225 PFAS concentrations were categorized into quartiles, and we set the main parameters of the
226 Hamiltonian Monte Carlo chain to optimize the accuracy and speed of the models. In total, we
227 set 1000 iterations, of which 500 were burn-in and 3 were thinned. All parameters showed no
228 autocorrelation between subsequent iterations, and the potential scale-reduction statistics,
229 which were approximately equal to 1 for all estimated parameters, showed convergence of the
230 chain to the equilibrium distributions ([Table S2](#)).

231
232 *Results in the overall adult population*

233 In the overall adult population there was no evidence of association between the PFAS mixture
234 and bone mineral density in lumbar spine ($\beta = -0.004$, 95% credible interval [CrI]: -0.04, 0.04)
235 g/cm², total femur ($\beta = 0.002$, 95% CrI: -0.04, 0.05) g/cm², or femur neck ($\beta = 0.005$, 95% CrI: -
236 0.03, 0.04) g/cm². Components of the mixture contributed approximately equally to the mixture
237 in the outcomes for the overall population ([Figures 3A, 4A, and 5A; Table S2](#)).

238
239 *Sensitivity analyses in the overall adult population*

240 Results from sensitivity analyses using the frequentist WQS approach, assuming a negative
241 direction between PFAS mixture and bone mineral density, were similar to those of BWQS. We
242 found no associations between the PFAS mixture and all outcomes (lumbar spine: $\beta = -0.01$, $p =$
243 0.69 ; total femur: $\beta = -0.01$, $p = 0.51$; femur neck $\beta = -0.004$, $p = 0.82$) using the validation hold
244 out set of 70% ([Figure S1, Table S3](#)). Individual PFAS analyses showed a weak negative
245 association among MPFOS and all bones (lumbar spine: -0.02, 95% CrI: -0.03, -0.009; total
246 femur: -0.01, 95% CrI: -0.02, -0.003; and femur neck -0.01, 95% CrI: -0.02, -0.004), whereas
247 PFNA was positively associated with total femur (0.04, 95% CrI: 0.01, 0.06) and neck femur
248 (0.03, 95% CrI: 0.01, 0.05) ([Figure S2, Table S4](#)). However, those associations did not persist
249 after correcting for multiple comparisons (data not shown).

250
251 *Results in men over 50 years old and in postmenopausal women*

252 There was no evidence of an association between the PFAS mixture and bone mineral densities
253 in men over 50 years old (lumbar spine: $\beta = 0.01$, 95% CrI: -0.05; 0.08; total femur $\beta = 0.01$, 95%

254 CrI: -0.04, 0.07; and femur neck $\beta = 0.02$, 95% CrI: -0.04, 0.07) or in postmenopausal women
255 (lumbar spine $\beta = 0.00$, 95% CrI: -0.08, 0.08; total femur $\beta = 0.02$, 95% CrI: -0.04, 0.08; and
256 femur neck $\beta = 0.02$, 95% CrI: -0.03, 0.08). The contribution of all mixture components was
257 similar across bones and across populations (Figures 3-5 panels B and C; Table S2).

258

259 Discussion

260 We extended the WQS regression under a Bayesian framework and determined the combined
261 association of eight PFAS with bone mineral density in lumbar spine and total and neck femur in
262 a survey representative U.S. adult population in the years 2013–2014. The main BWQS
263 characteristics include diagnostic statistics for all estimated parameters, and BWQS does not
264 require a priori selection of the directionality of the coefficient associated with the mixture or
265 splitting the original dataset, thus overcoming a few limitations of the frequentist approach.

266

267 The application of our novel method showed no evidence of the association between serum
268 concentration of PFAS mixture, composed of linear and branched PFOS and PFOA isomers
269 (NPFOS, NPFOA, and MPFOS) and PFHS, PFNA, PFDE, MPAH, and PFUA, and bone mineral
270 density in lumbar spine and total and neck femur. The contribution of each compound was
271 similar across bones. Results were also consistent using the frequentist WQS approach and
272 Bayesian linear regressions.

273

274 Our results confirmed prior findings showing null associations between PFAS exposure and
275 bone health in the overall adult U.S. population. Serum concentrations of individual PFAS,
276 namely, PFOA, PFOS, PFHS, and PFNA, were not associated with mineral density in spine
277 and total and neck femur in the overall adult population in the 2009–2010 NHANES cycle.²²
278 Previous findings showed that associations between a few individual PFAS compounds and
279 bone mineral density were negative and significant in women only, with higher concentrations of
280 PFOA, PFOS, PFHS, and PFNA associated with lower bone mineral density and with a higher
281 risk osteoporosis in women.²² However, those analyses ignored the correlations among those
282 compounds and did not consider PFAS as a mixture, thereby increasing the number of false
283 positives among significant results.

284

285 Epidemiological studies support the hypothesis that PFAS are endocrine disruptors. PFAS
286 modulate thyroid and sex hormone concentrations, which play a critical role in bone remodeling
287 and health³³. Chronic PFAS exposure was associated with suppressed serum thyroxine and

288 triiodothyronine (T3) levels in human studies^{34,35} and with altered responses to T3 in a T3-
289 dependent cell line *in vitro*.³⁶ A cross-sectional study of adult NHANES participants³⁵ reported
290 that serum PFHS was positively associated with subclinical hyperthyroidism in women, which is
291 a risk factor for decreased bone mass.³⁷ PFAS also interfere directly with estrogen and
292 androgen receptors, disrupting the biological effects of sex hormones and leading to reduced
293 fecundity in women and delayed puberty in boys, both of which are associated with lower bone
294 mineral density later in life.^{23,38} In studies of women's health, PFAS were associated with
295 decreased production of estradiol and progesterone, which are essential hormones for bone
296 health due to their promotion of osteoblast activity. Based on this body of literature, the PFAS
297 mixture, mediated by endocrine receptors, might affect bone mineral density, but further studies
298 with longitudinal design are required to address this problem.

299
300 We also found no evidence of an association between the PFAS mixture and bone mineral
301 density in vulnerable populations, including men over 50 years old and postmenopausal women.
302 However, our results could have been limited by a small number of participants (n = 115 and
303 117, respectively). Also, men and women in this study were not asked whether they attempted
304 to prevent bone deterioration by changes in lifestyle, such as using supplements or alternative
305 treatments or eating a healthier diet.

306
307 PFOA and PFOS, both of which were previously associated with bone mineral density in women
308^{19,22} were analyzed and decomposed in linear and branched isomers in our analyses, and we
309 could not confirm previous results for those compounds. Due to the cross-sectional design of
310 our study, we could not rule out whether it was reverse causation and PFAS exposure preceded
311 the outcomes or bone mineral status affected the response to exposure³⁹. It is also possible
312 that our results may have been limited by the smaller number of participants (n=499) than other
313 study showing an association between the exposure of a few PFAS and bone mineral density
314 (n=1914).²² Further studies with longitudinal design and larger sample size could help to
315 disentangle the underlying mechanism linking PFAS exposure and bone health in older adults.

316
317 The strengths of our study include a novel statistical approach, which accounted for the
318 correlation among co-occurring PFAS and provided information about the overall adverse
319 associations of PFAS and bone density. We used a sample that is known to represent the U.S.
320 population in the years 2013–2014, and we relied on PFAS concentrations and bone mineral
321 density levels that were validated and compared across NHANES cycles.

322

323 **Conclusions.** This is the first study to assess the relationship between exposure to a mixture of
324 PFAS and bone mineral density at three bone sites. The novel Bayesian WQS approach
325 identified both the overall association between PFAS mixture with bone mineral density and the
326 contribution of each PFAS to the mixture. The serum PFAS mixture showed no association with
327 mineral density of the lumbar spine and total and neck femur in the NHANES adult population in
328 the years 2013–2014.

443 **Table 1.** NHANES characteristics for the overall adult population, men over 50 years old, and
 444 postmenopausal women*

Characteristics	Overall adult population	Men over 50 years old	Postmenopausal women
	n=499 N = 64,978,899 Mean ± SE	n=115 N = 11,904,882 Mean ± SE	n=117 N = 14,570,823 Mean ± SE
Spine bone density (g/cm ²)	1.012 ± 0.009	1.047 ± 0.018	0.945 ± 0.019
Femur bone density (g/cm ²)	0.945 ± 0.007	0.989 ± 0.142	0.868 ± 0.013
Femur neck density (g/cm ²)	0.780 ± 0.007	0.794 ± 0.015	0.712 ± 0.013
Poverty-income ratio	2.882 ± 0.090	2.893 ± 0.217	2.753 ± 0.178
Age (years)	54.732 ± 0.632	62.656 ± 1.022	59.410 ± 1.218
Sex: N (%)			
Male	24,756,638 (38%)	11,904,882 (100%)	0 (0%)
Female	40,222,261 (62%)	0 (0%)	14,570,823 (100%)
Race: N (%)			
Mexican American	8,171,809 (12%)	1,470,648 (12%)	2,015,869 (14%)
Other Hispanic	5,506,180 (9%)	502,741 (4%)	1,058,314 (7%)
Non-Hispanic White	31,720,096 (49%)	6,007,804 (51%)	7,206,459 (49%)
Non-Hispanic Black	11,388,109 (17%)	2,721,619 (23%)	2,718,160 (19%)
Other	8,192,706 (13%)	1,202,068 (10%)	1,572,021 (11%)
Smoking status: N (%)			
Ever	25,731,955 (40%)	6,396,599 (54%)	4,316,813 (30%)
Never	39,246,944 (60%)	5,508,283 (46%)	10,254,011 (70%)
Physical activity: N (%)			
Vigorous	21,844,374 (34%)	4,434,527 (37%)	2,907,339 (20%)
Not vigorous	43,134,525 (66%)	7,470,355 (63%)	11,663,484 (80%)
PFAS (ug/L): 50 th (25 th , 75 th) percentile			
NPFOA	2.00 (1.30, 3.10)	2.60 (1.90, 3.70)	1.83 (1.20, 3.00)
NPFOS	4.10 (2.50, 7.40)	6.21 (3.50, 9.98)	4.10 (2.70, 7.60)
MPFOS	1.80 (0.90, 3.00)	3.24 (2.10, 4.30)	1.70 (1.07, 2.94)
MPAH	0.07 (0.07, 0.20)	0.10 (0.07, 0.30)	0.07 (0.07, 0.20)
PFDE	0.20 (0.10, 0.40)	0.20 (0.10, 0.40)	0.20 (0.10, 0.34)
PFHS	1.40 (0.80, 2.40)	2.10 (1.60, 3.56)	1.30 (0.80, 2.40)
PFNA	0.80 (0.50, 1.30)	0.90 (0.60, 1.30)	0.70 (0.50, 1.20)
PFUA	0.10 (0.07, 0.20)	0.10 (0.07, 0.20)	0.07 (0.07, 0.20)

445 See Table S1 for PFAS abbreviations. * NHANES sampling weights were applied for calculation
 446 of demographic descriptive statistics and therefore Ns for frequencies represent the weighted
 447 sample size.
 448
