106

107 **Abstract:**

108 **Objectives:** The rapidly evolving coronavirus disease 2019 (COVID-19), was declared a
109 pandemic by the World Health Organization on March 11, 2020. It was first detected in the city of
110 Wuhan in China and has spread globally resulting in substantial health and economic crisis in
111 many countries. Observational studies have partially identified the different aspects of this
112 disease. Up to this date, no comprehensive systematic review for the clinical, laboratory,
113 epidemiologic and mortality findings has been published. We conducted this systematic review
114 and meta-analysis for a better understanding of COVID-19.

115 **Methods:** We reviewed the scientific literature published from January 1, 2019 to March 3, 2020.
116 Statistical analyses were performed with STATA (version 14, IC; Stata Corporation, College
117 Station, TX, USA). The pooled frequency with 95% confidence intervals (CI) was assessed using
118 random effect model. Publication bias was assessed and $p < 0.05$ was considered a statistically
119 significant publication bias.

120 **Results:** Out of 1102 studies, 32 satisfied the inclusion criteria. A total of 4789 patients with a
121 mean age of 49 years were evaluated. Fever (83.0%, CI 77.5 to 87.6), cough (65.2%, CI 58.6 to
122 71.2) and myalgia/fatigue (34.7, CI 26.0 to 44.4) were the most common symptoms. The most
123 prevalent comorbidities were hypertension (18.5 %, CI 12.7 to 24.4) and Cardiovascular disease
124 (14.9 %, CI 6.0 to 23.8). Among the laboratory abnormalities, elevated C-Reactive Protein (CRP)
125 (72.0% (CI 54.3 to 84.6) and lymphopenia (50.1%, CI 38.0 to 62.4) were the most common
126 findings. Bilateral ground-glass opacities (66.0%, CI 51.1 to 78.0) was the most common CT-Scan

127 presentation. Pooled mortality rate was 6.6%, with males having significantly higher mortality
128 compared to females (OR 3.4; 95% CI 1.2 to 9.1, P=0.01).

129 **Conclusion:** COVID-19 commonly presented with a progressive course of cough and fever with
130 more than half of hospitalized patients showing leukopenia or a high CRP on their laboratory
131 findings. Mortality associated with COVID19 was higher than that reported in studies in China
132 with Males having a 3-fold higher risk of mortality in COVID19 compared to females.

133

134 **Summary box:**

135 **What is already known in this topic:**

- 136 • COVID-19 was declared a pandemic by the World Health Organization on March 11, 2020.
- 137 • Many observational studies have separately dealt with different clinical and epidemiologic
138 features of this new and rapidly evolving disease.
- 139 • Very few systematic reviews about COVID-19 have been done and there was still a need
140 for a systematic review and meta-analysis related to the clinical findings and the mortality
141 of the disease in order to have a better understanding of COVID-19.
- 142 • Previous reports have indicated that older age and presence of multiple comorbidities are
143 associated with increased mortality.

144 **What this study adds:**

145 • The mortality rate in our study for hospitalized COVID-19 patients was 6.6% and males
146 had around 3-fold higher risk of mortality compared to females (OR 3.4; 95% CI 1.2-9.1,
147 P=0.01).

148 • These findings could indicate the need for more aggressive treatment of COVID-19 in
149 males.

161

162 **Introduction**

163 Facing an immediate crisis by the novel coronavirus, Severe Acute Respiratory Syndrome
164 Coronavirus 2, (SARS-CoV-2), which has been called the once in a century pathogen requires a
165 global response to this outbreak(1). The disease caused by this virus has been named
166 “coronavirus disease 2019” (COVID-19) by the World Health Organization. As of now, more than
167 168 countries have reported COVID19 patients. Given the increasing number of countries infected
168 with SARS-CoV-2, WHO declared COVID19 a pandemic on March 11, 2020.(2) The SARS-CoV-
169 2 virus is a betacoronavirus and like the Middle East Respiratory Syndrome virus (MERS-CoV)
170 and SARS-CoV that caused the previous respiratory syndrome outbreaks, belongs to the family
171 of coronaviruses. However, this is the first pandemic caused by a member of the coronavirus
172 family (3).

173

174 COVID19 started in China in December 2019 when a cluster of patients with pneumonia of
175 unknown cause was identified in the city of Wuhan. Since then, it has infected hundreds of
176 thousands of people around the world and resulted in more than 13000 deaths up to this date (4).
177 Despite governmental travel restrictions in many countries, the confirmed number of new cases
178 has been rising globally. The international community has asked for at least US\$675 million for
179 preparedness and protection of states with weaker health systems (5).

180

181 In the previous two outbreaks of coronaviral respiratory illness, namely Severe Acute Respiratory
182 Illness (SARS) and Middle East Respiratory Illness (MERS), gender-based difference in mortality
183 was observed. In SARS, younger males were at twice the risk of death compared to females and
184 the difference in mortality reduced with older age(6). The case fatality rate observed in males was
185 twice that of females in MERS (7). The effect of sex on COVID-19 mortality was unknown. We
186 evaluated this risk for COVID-19 patients as well.

187
188 The novelty of COVID19 has raised many questions about the epidemiology of the disease,
189 clinical and laboratory methods of diagnosis as well as therapeutic measures. Thus far, many
190 observational studies have been dealing with these features separately, however, there is still a
191 necessity for more systematic reviews specially to understand role of the sex in mortality of
192 COVID19. In this meta-analysis study, we reviewed the published literature from January 1, 2019
193 to March 3, 2020 to provide an overview for a better understanding of COVID-19.

194

195 **Methods**

196 *Search strategy*

197 We searched Pubmed/Medline, Embase, Web of Science and the Cochrane Library for studies
198 published from January 1, 2019 to March 3, 2020. The search strategy was based on the following
199 key-words: COVID-19, severe acute respiratory syndrome coronavirus 2, novel coronavirus,
200 SARS-CoV-2, nCoV disease, SARS2, COVID19, Wuhan coronavirus, Wuhan seafood market

201 pneumonia virus, 2019-nCoV, coronavirus disease-19, coronavirus disease 2019, 2019 novel
202 coronavirus and Wuhan pneumonia. Lists of references of selected articles and relevant review
203 articles were hand-searched to identify further studies. This study was conducted and reported
204 according to the PRISMA guidelines (8). The study did not require any ethics committee approval.
205 This research was done without patient involvement. Patients were not invited to comment on the
206 study design and were not consulted to develop patient relevant outcomes or interpret the results.
207 Patients were not invited to contribute to the writing or editing of this document for readability or
208 accuracy.

209 *Study Selection*

210 The records found through database searching were merged and the duplicates were removed
211 using EndNote X7 (Thomson Reuters, New York, NY, USA). Two reviewers (YF and PJ)
212 independently screened the records by title and abstract to exclude those not related to the current
213 study. The full texts of potentially eligible records were retrieved and evaluated by a third reviewer
214 (AT). Included studies met the following inclusion criteria: (i) patients were confirmed and
215 diagnosed with RT-PCR as suggested by WHO; (ii) The raw data for clinical, radiological and
216 laboratory findings were included; and (iii) the outcomes were addressed. Studies with insufficient
217 information about patients' characteristics and outcomes were excluded. Case reports, reviews,
218 and animal studies were also excluded. Only studies written in English were selected.

219 *Data extraction and quality assessment*

220 A data extraction form was designed by two reviewers (AZ and SH). These reviewers extracted
221 the data from all eligible studies and differences were resolved by consensus. The following data
222 were extracted: first author name; year of publication; type of study, country/ies where the study
223 was conducted; distribution of age and sex in the population, number of patients investigated,
224 data for clinical, radiological and laboratory findings, and outcomes.

225 *Data Synthesis and Analysis*

226 Statistical analyses were performed with STATA (version 14, IC; Stata Corporation, College
227 Station, TX, USA). The pooled frequency with 95% confidence intervals (CI) was assessed using
228 random effect model. The between-study heterogeneity was assessed by Cochran's Q and the
229 I² statistic. Publication bias was assessed statistically by using Begg's and Egger's tests ($p < 0.05$
230 was considered indicative of statistically significant publication bias).

231 *Quality assessment*

232 The checklist provided by the Joanna Briggs Institute (JBI) was used to perform quality
233 assessment(9).

234

235 **Results**

236 The search yielded 1102 publications, of which 259 potentially eligible studies were identified for
237 full-text review, resulting in 32 studies fulfilling the inclusion criteria (Figure 1) (Table1). The mean

238 age of the patients was 49.0 years and 4789 patients were included. Based on JBI tool, the
239 included studies had a low risk of bias.

240 *Clinical manifestations*

241 The most common signs and symptoms were fever (83.0%, CI 77.5-87.6), cough (65.2%, CI 58.6-
242 71.2), dyspnea (27.4%, CI 19.6-35.2), myalgia/fatigue (34.7, CI 26.0-44.4) followed by hemoptysis
243 (2.4%, CI 0.8-6.7), diarrhea (5.7%, CI 3.8-8.6) and nausea/vomiting (5.0 %, CI 2.3-10.7). Sputum
244 production (17.2%, CI 10.8-26.4) was a relatively common symptom. (Table 2).

245 *Comorbidities*

246 The most common comorbidities were respectively hypertension (18.5 %, CI 12.7-24.4),
247 cardiovascular diseases (14.9 %, CI 6.0-23.8), diabetes (10.8 %, CI 8.3-13.3), chronic liver
248 disease (8.1, CI 4.6-11.6) and smoking (8.0%, CI 2.3-13.6) (Table 3).

249 *Laboratory findings*

250 The most frequent abnormal laboratory findings in patients with COVID-19 were respectively,
251 increased C-Reactive Protein (CRP) (72% CI 54.3-84.6), lymphopenia (50.1%, CI 38.0-62.4), high
252 levels of Lactate Dehydrogenase (LDH) (41%,CI 22.8-62.0), increased serum aspartate
253 aminotransferase (19.7%, CI 10.5-33.7) and thrombocytopenia (11.1%, CI 7.7-15.7) (Table 4).
254 Among the confirmed COVID19 subjects, 14.0% (CI, 6.7-29.0) had viremia. Impaired hepatic
255 function with ALT levels greater than 47.25 U/L was seen in 13.3% (CI 3.2-41.0) of COVID19
256 subjects. Acute cardiac injury with troponin levels greater than 28 pg/ml was seen in 12.4% of

257 the patients. Acute kidney injury was found in 5.5% (CI 1.3-20.8). Shock was reported in 4.0% (CI
258 1.6-12.0) shock. 13.0% (CI 4.8-30.0) met the definition of acute respiratory distress syndrome
259 (ARDS).

260 *Radiologic findings*

261 Chest X-Ray (CXR) and chest CT-scan were the common imaging modalities used for the
262 diagnosis of COVID19. The pooled sensitivity for CT-scan for COVID19 was 79.3%. The most
263 common sites of the lung involvement based on chest CT-scan were right lower lobe (76.2, CI
264 57.8-82.5) followed by left lower lobe (71.8%, CI 57.8-82.5). Most of the patients (74.8%) had
265 bilateral involvement. The most common pattern of parenchymal involvement was ground-glass
266 opacity (66.0%, CI 51.1-78.0). The chest CT-scan was reported normal in 20.7% of the patients
267 with confirmed RT-PCR results (Table 5).

268 *Outcomes*

269 Hospitalization was required in 94.6% of patients with severe COVID-19. The pooled mortality
270 rate of these patients was about 6.6% (CI 2.8-15.0) (Table 6, 7). Old age, male sex, presence of
271 underlying diseases, higher level of D-dimer, lower level of fibrinogen and anti-thrombin,
272 progressive radiographic deterioration in follow up CT-scans, developed ARDS and requirement
273 of mechanical ventilation were reported factors associated with increased mortality rate. As shown
274 in Table 8, men had significantly higher mortality in the hospital compared to women (OR 3.4;
275 95% CI 1.2-9.1, P=0.01). Although ICU admission was higher in men, the difference was not
276 significant. The mean duration between the time of hospitalization and death was 17.5 days with

277 minimum and maximum periods of 14 and 21 days respectively. The effects and summaries
278 calculated using a random-effects model weighted by the study population is shown in Figure 2.

279

280

281 **Discussion**

282 We evaluated the signs and symptoms, diagnostic modalities, therapeutic measures and
283 epidemiologic features of COVID-19 to have a better understanding of this pandemic caused by
284 SARS-CoV-2. In terms of clinical manifestations, the most common signs and symptoms were
285 fever and cough. Hypertension and cardiovascular diseases were the most common
286 comorbidities among patients. Between the different abnormal laboratory findings, increased
287 levels of CRP and lymphopenia were the most common findings. Chest X-Ray and chest CT-scan
288 were the most common imaging modalities used for the diagnosis. The pooled sensitivity of CT-
289 scan for COVID19 was 79.3%. We found 20.7% of the patients with confirmed RT-PCR who had
290 normal chest CT-Scan suggesting that a normal chest CT-scan cannot rule out the disease in
291 patients who are highly suspicious for COVID-19. Several complications were seen due to
292 COVID-19. Among these, acute hepatitis was the most common one occurring in 13.3% of cases,
293 followed by cardiac injury with troponin levels greater than 28 pg/ml seen in 12.4%. The pooled
294 mortality rate of these patients was 6.6%. We detected several factors contributing to a worse
295 outcome including old age, male sex, presence of underlying diseases and some abnormal
296 laboratory finding such as high level of D-Dimer. Although there was not any significant difference

297 between male and female gender in ICU admissions, male gender showed a significantly higher
298 in-hospital mortality rate.

299
300 The current study showed that fever (83.0%), cough (65.2%) and dyspnea (27.4%) were the most
301 common signs and symptoms. In a study done by Zhang et al in Wuhan, fever was identified as
302 the most common clinical finding present in 91.7% of the patients followed by cough in 75% of
303 patients. Their study showed a higher gastrointestinal (GI) manifestation at presentation of the
304 disease, representing 39.6% of the patients (10). Our study showed a lower prevalence of GI
305 symptoms including diarrhea, which was present in 5.7% of patients and nausea/vomiting in 5%.

306
307 The most prevalent comorbidities in our study were hypertension (18.5 %, CI 12.7-24.4) followed
308 by cardiovascular diseases (14.9 %, CI 6.0-23.8) and diabetes (10.8 %, CI 8.3-13.3). According
309 to a systematic review for comorbidities by Yang et al, hypertension ($17 \pm 7\%$, CI 14-22%) and
310 diabetes ($8 \pm 6\%$, CI 6-11%), followed by cardiovascular diseases ($5 \pm 4\%$, CI 4-7%) were the
311 most common comorbid findings (11). The high prevalence of hypertension and other
312 cardiovascular comorbidities have raised speculation regarding the role of angiotensin-converting
313 enzyme Inhibitors (ACEI) in COVID-19. Angiotensin-converting enzyme 2 (ACE2) receptor has
314 been identified as the receptor used by SARS-CoV-2 to infect human cells and previous studies
315 have shown that the usage of ACEI results in the upregulation of ACE2 (12) (13). Theoretically,
316 this increase in ACE2 levels could result in a greater risk of infection with the SARS-CoV-2 virus.

317 Current evidence against the use of ACEI in patients with COVID-19 or those at risk of the disease
318 is limited, and further studies are needed to analyze this possible association.

319

320 The most common laboratory abnormalities were elevated C-Reactive Protein (CRP) (72%),
321 lymphopenia (50.1%) and elevated LDH (41%). Also, thrombocytopenia was seen in 11.1% of
322 the subjects. Analyses by Huang et al and Lippi et al have suggested that lymphopenia and
323 thrombocytopenia in COVID-19 patients are associated with poorer outcomes, respectively (14,
324 15). Interestingly, patients with SARS were reported to have a higher percentage of lymphopenia
325 (68-90%) and thrombocytopenia (20-45%) compared to COVID-19 patients (16). A similar
326 reduction in counts was also observed in patients with H1N1 influenza (17). Thrombocytopenia
327 and lymphopenia have been previously shown to strongly indicate a higher risk of mortality in
328 SARS and influenza (17, 18). Given the current lack of predictive biomarkers in COVID-19,
329 lymphocyte and platelet count may be used as indicators of severe disease in the clinical setting.

330

331 Liver abnormality was the most common complication and was present among 13.3% of the
332 subjects, although the data was reported only in 3 studies. However, a significant number of
333 subjects had elevated AST (19.7%) and ALT (14.6%). Impaired liver function has been observed
334 as collateral damage in some viral infections including SARS, possibly caused by direct damage
335 to the hepatic tissue by the pathogen (19). While this could be the case with COVID19, an
336 iatrogenic effect due to medications like lopinavir cannot be ruled out.

337

338 Another significant finding in our analysis was the incidence of cardiac injury in 12.4% of the
339 patients, which is a common event seen in a multitude of viral illnesses(20). Gao et al observed
340 that subjects with influenza (H7N9) and cardiac injury had an elevated risk of mortality (HR=2.06)
341 (21). In a study by Ludwig et al for analysis of cardiac biomarkers in influenza patients, 24% of
342 the subjects showed ACI in ≤ 30 days after influenza diagnosis and half of them were myocardial
343 infarction (22). Although our analysis did not show increased mortality risk in patients with cardiac
344 injury, these findings could indicate the potential need for identifying and optimizing cardiac risk
345 factors in COVID-19 patients during the treatment period.

346

347 The mean duration between hospitalization and death was 17.5 days (range- 14-21 days),
348 compared to 17.4 days in SARS (23). The overall mortality rate in this study was 6.6%, which is
349 more than twice than previously reported (24). Though comparable mortality was reported by Li
350 et al (7%) and Qian et al (8.9%) in their meta-analyses, a study by Rodriguez et al showed a much
351 higher death rate of 13.9% (25-27). On the other hand, a study from the Jiangsu province of China
352 results showed a high cure rate equal to 96.67%. Although the main reason for very low mortality
353 on this study remains unknown, measures including early recognition and centered-quarantine
354 may be contributing factors(28).

355

356 Of note, the in-hospital mortality of males was significantly higher than females (OR 3.4; 95% CI
357 1.2-9.1, $P=0.01$). A similar pattern of higher mortality in males has been reported in previous
358 coronavirus outbreaks of SARS and MERS. Karlberg et al also reported that the gender-based

359 difference in mortality was higher in younger males (0-44 years) (RR=2), compared to those of
360 age group 45-74 (RR-1.45) (6). Similarly, the study by Alghamdi et al showed that the case fatality
361 rate in males was twice that of females in MERS (52% VS 23%) (29). Although a gender-based
362 difference in the immune response to infections has been suggested as a possible factor, other
363 contributing factors including smoking history and severity of underlying comorbidities cannot be
364 ruled out (30). This is especially of significance in China, where the prevalence of smoking among
365 men (57.6%) is almost 10 times higher than in women (6.7%) (31). This difference in mortality
366 opens the discussion for the need to treat COVID19 more aggressively in males, including the
367 possibility of earlier intubation and mechanical ventilation in this population. Further investigations
368 are also needed to understand this phenomenon.

369
370 This study has several limitations. Due to the rapidly emerging COVID-19 situation around the
371 globe and the novelty of this coronavirus, there is still limited clinical data regarding diagnostic
372 modalities and effective therapeutic measures. Most of the clinical findings were from
373 observational studies. Future clinical trials and animal models are also required to have
374 conclusive clinical information. We also need more studies outside of China for a comprehensive
375 result that reflects COVID-19 globally. In the end, due to the lack of accurate reports of the new
376 cases in different countries, the epidemiologic measures are also limited. As this pandemic is
377 growing fast, future studies are needed for the evaluation of epidemiologic and clinical features
378 of COVID-19.

379

380 **Conclusion:**

381 COVID-19 presents with a significant number of mortalities especially among males around the
382 world. The pooled mortality rate in our study was 6.6%. The high rate of hospitalization and case
383 fatality among hospitalized patients along with the lack of intensive care facilities necessitated the
384 identification of factors associated with the severe disease and mortality. These factors included
385 male gender, age, underlying diseases, higher level of D-Dimer, lower level of fibrinogen and anti-
386 thrombin, progressive radiographic deterioration on follow up, developed ARDS and requirement
387 of mechanical ventilation. It was inferred that higher comorbidities such as hypertension and
388 cardiovascular diseases could be related to the pathogenesis of the virus through ACE II receptor.
389 This association could open doors for future studies to evaluate the role of ACE inhibitor drugs in
390 the high-risk group. There are still a lot of unknown features of COVID-19 for the broad scientific
391 community to investigate in an effort to slow the progression and mortality of COVID-19 and finally
392 defeat this pandemic.

Table 6. Meta-analysis of complications

	Number of studies	Pooled frequency (95% CI)	n/N*	Publication bias (p value)	Heterogeneity test	
					I ² (%)	p value
RNAemia	1	14.0 (6.7-29.0)	6/41	NA	0.00	1.00
ARDS	9	13.0 (4.8-30.0)	142/1794	0.67	96	0.00
Acute cardiac injury	4	12.4 (6.2-23.2)	28/243	0.83	65	0.03
Acute kidney injury	6	5.5 (1.3-20.8)	34/1441	0.58	93	0.00
Liver failure	3	13.3 (3.2-41.0)	20/144	0.50	84	0.00
Shock	5	4.0 (1.6-12.0)	32/1389	0.60	86	0.00
Hospitalization	10	94.6 (73.8-99.1)	1561/1829	0.76	98	0.00

Table 7. Meta-analysis of outcomes

	Number of studies	Pooled frequency (95% CI)	n/N*	Publication bias (p value)	Heterogeneity test	
					I ² (%)	p value
Discharged	14	52.7 (36.5-68.4)	486/948	0.44	93	0.00
Death	11	6.6 (2.8-15.0)	111/2026	0.50	93	0.00

Table 8. Mortality and ICU admission in men vs women in patients with COVID-19

	Number of studies	Pooled OR (95% CI)	p value	Heterogeneity test	
				I ² (%)	p value
Mortality in men vs women	2	3.4 (1.2-9.1)	0.01	0.00	0.6
ICU admission in men vs women	2	1.6 (0.7-3.2)	0.1	0.00	0.5

Figures legends:

Figure1. Flow chart of study selection for inclusion in the systematic review and meta-analysis.

Figure 2. The pooled mortality rate of patients with COVID-19. Effects and summaries were calculated using a random-effects model weighted by study population.
