24 **Abstract**

25 **Background:** Occupational exposure to blood and body fluids is a major risk factor for the
26 transmission of blood-borne infections to healthcare workers. There are several primary studies
27 in Ethiopia yet they might not be at the national level to quantify the extent of occupational
28 blood and body fluid exposures among the healthcare workers. This systematic review and meta-
29 analysis aimed to estimate the pooled prevalence of occupational blood and body fluid exposure
30 of health-care workers in Ethiopia.

31 **Methods:** PubMed, Science Direct, Hinari, Google Scholar, and the Cochrane library were
32 systematically searched; withal, the references of appended articles were also checked for further
33 possible sources. The Cochrane Q test statistics and I^2 tests were used to assess the
34 heterogeneity of the included studies. A random-effects meta-analysis model was used to
35 estimate the lifetime and 12-month prevalence of occupational exposure to blood and body fluids
36 among health-care workers in Ethiopia.

37 **Results:** Of the 641 articles identified through the database search, 37 studies were included in
38 the final analysis. The estimated pooled lifetime and 12-month prevalence on occupational
39 exposure to blood and body fluids among healthcare workers were found to be at 54.15% (95%
40 confidence interval (CI): 47.54–60.75) and 44.24% (95%CI: 36.98-51.51), respectively. The
41 study identified a variation in healthcare workers whom were exposed to blood and body fluids
42 across Ethiopian regions.

43 **Conclusion:** The finding of the present study revealed that there was a high level of annual and
44 lifetime exposures to blood and body fluids among the healthcare workers of Ethiopia.

45 **Keywords:** Blood and body fluid, Ethiopia, Healthcare workers, Occupational exposure, Splash
46

47 **Introduction**

48 Occupational exposure to blood and body fluids (BBFs) is a major risk factor for the
49 transmission of blood-borne infections to healthcare workers (HCWs). These exposures can
50 heighten the risk of infection to Human Immunodeficiency Virus (HIV), Hepatitis B, and
51 Hepatitis C. In many cases, exposures occur through a needle stick or contact in the eyes, nose,
52 mouth, or when a broken skin comes in contact with the patient's blood or body fluid [1,2].

53 According to the World Health Organization (WHO), it is estimated that about 3 million HCWs
54 are exposed to bloodborne pathogens each year – occupational exposure causes approximately
55 170,000 to HIV infections, 2 million to HBV infections, and 0.9 million to HCV infections [3].
56 A recent review also stipulated that the prevalence of infections, such as HCV is significantly
57 higher in HCWs than in the general population [1]. And more than 90% of HIV, HBV, and HCV
58 exposures transpire in the developing countries [4].

59 Antecedent literatures publicized that blood or blood products accounted for 66% of exposures
60 and the remaining involved vomits, urines, amniotic fluids, and cerebrospinal fluids; saliva;
61 sputum; and other BBFs; 28% of these cases were fluids which contained visible bloods, and in
62 some exposure incidents, multiple body areas were splashed or sprayed with these body fluids.
63 The face is the most common exposure site reported: healthcare workers' eyes (conjunctiva) were
64 exposed to BBF (53%) of all reported cases. The mucosa of the mouth and nose were exposed in
65 11% and 5% of cases, respectively [5,6,7].

66 In sub-Saharan Africa, HCWs are at consequential risk of infection from blood-borne pathogens
67 because of the excessive prevalence of such blood-borne infections in the general population
68 [5,8]. A systematic review conducted in 21 African countries found a high prevalence of
69 occupational exposures to blood and body fluids among HCWs – about two-thirds were exposed
70 during their entire career, and almost half of them were exposed each year [9]. Additionally,
71 evidence from every region of Africa indicates considerable variations in the prevalence of blood
72 and body fluid exposures. The 12-month prevalence of all the types of occupational exposure to
73 blood and body fluids ranged from 17.0% to 67.6% in Kenyan and Burundian studies. The
74 estimated pooled 12-month prevalence was 48.0%. Regional pooled estimates covered from
75 33.9% to 60.7% in Southern Africa and Northern Africa [9].

76 In Ethiopia, occupational exposure to BBFs is a pressing concern and continues to have a
77 significant problem in its healthcare system [10-14]. Antecedent studies also reported that

78 standard precaution practices among HCWs were suboptimal, and the lack of compliance with
79 these measures is still a great lookout [11, 13, 15, 16]. Though attention is paid to the safety of
80 HCWs through the National Infection Prevention and Patient Safety (IPPS) initiatives, the
81 number of exposures to BBFs reported did not manifest a sign of decline as evidenced by some
82 studies [11,14,15,18].

83 Several primary studies in Ethiopia conveyed a high prevalence of occupational exposures to
84 BBFs. However, the results were inconsistent [11,16-23]. For some instances, in Central
85 Ethiopia, the prevalence of a 12-month BBF exposures among HCWs was 19.9% [11] and
86 41.3% [20]; in North Ethiopia 60.2% [16] and 31.7% [21]; and in East Ethiopia 43.8% [17] and
87 20.2% [14]. Currently in Ethiopia, no report exists to quantify the pooled prevalence of BBF
88 exposures among its HCWs, even the existing review determined the prevalence of needle stick
89 injury and did not estimate BBF exposures [24]. Moreover, the epidemiology of blood-borne
90 infections in Ethiopia is on the rise and dynamically changing over the past decades, along with
91 poor compliance toward standard precautions among HCWs. Given these developments, it is
92 timely and crucial to investigate the burden of occupational BBF exposures among HCWs.
93 Therefore, the objective of the present systematic review and meta-analysis directs to estimate
94 the pooled prevalence of BBFs among HCWs in Ethiopia.

95

96 **Methods**

97 This systematic review and meta-analysis were conducted subsequent to "the Preferred
98 Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA)" guidelines [25]. Studies
99 were favoured according to the criteria outlined below (**Appendices A**).

100

101 **Eligibility Criteria**

102 **Study Designs and**

103 In this review, we appended cross-sectional studies and baseline assessment of longitudinal
104 studies. Studies that reported the lifetime and/or 12-month prevalence of occupational exposure
105 through blood and/or body fluid exposures to mucous membranes and broken skins were eligible
106 to be included in the present review. Systematic reviews, letters to editors, short
107 communications, qualitative studies, case series, case-control studies, and case reports were
108 excluded. Also, articles that were not fully accessible, unsuccessful two-email contacts with the
109 primary/corresponding authors were excluded, too. In addition to the aforementioned, studies
110 restricted to HCWs' needle stick and/or sharp injuries were excluded when data were not
111 provided separately for blood and body fluid exposures. Lastly, the aggregate reports for blood
112 and/or body fluid exposures and needle stick and/or sharps injuries were debarred from the
113 study.

114

115 **Participants**

116 Studies who met the following criteria were considered for inclusion:

117 Population: Healthcare works (HCWs) with direct contact to patients or blood/body fluids. We
118 also encompassed studies which were conducted on a specific segment of the healthcare
119 workforce (such as physicians, nurses, midwives, laboratory technicians, and cleaners).

120 Exposure: study examines occupational BBFs exposures

121

122 **Study Period**

123 No restriction on publication date.

124

125 **Language**

126 Articles which were only reported in the English language.

127

128 **Article Searching Strategy**

129 MEDLINE/PubMed, Hinari, Science Direct, and the Cochrane Library databases from inception
130 until January 31, 2020, that reported the prevalence of occupational exposures to blood and/or
131 body fluids among HCWs in Ethiopia were sought. Literature search strategies were developed
132 using medical subject headings (MeSH) and text words related to occupational blood and/or
133 body fluid exposures. The following search terms were used and combined using Boolean
134 operators: "prevalence", "magnitude", "occupation", "exposure", "accident", "occupational
135 exposure", "accidental exposure", "accidental occupational exposure", "occupational disease",
136 "occupational hazard" , "cross-infection", "blood", "body fluid", "blood spill", "blood-borne
137 pathogens", "blood-borne infection", "health-care workers", "health workers", "medical
138 personnel", "health personnel" and "Ethiopia". The electronic database search was also
139 supplemented by searching for gray literature through Google scholar, Google searching, and
140 Ethiopian University digital repositories (such as the Addis Ababa University Digital Library).
141 To ensure literature saturation, the reference list of appended studies and/or relevant studies
142 identified through the search were scanned as well. Finally, the literature search was limited to
143 the English language and human subjects (**Appendices B**).

144

145 **Operational Definition**

146

147 **Occupational Blood and Body Fluid Exposure:** In this review, "occupational blood and body
148 fluid exposure" is defined as any exposure to potentially harmful biological agents or infectious
149 materials that occurs as a result of one's occupation, which includes the patient's blood and other
150 body fluids. We appended studies that reported the lifetime or 12-month prevalence of
151 occupational exposure through blood and body fluid contacts from at least one of these routes
152 (eye, mouth, mucous membrane, and non-intact skin).

153

154 **Healthcare Workers:** Healthcare workers (HCWs) are referred to as paid or unpaid individuals
155 (eg: full-time employees or medical students) working in a health-care setting whose activities
156 involve direct contact with patients, or with blood or other body fluids from the patients. Hence,
157 we incorporated studies which involved physicians, nurses, midwives, health officers, laboratory

158 technicians, anesthetists, auxiliary healthcare workers, residents, or interns undertaking clinical
159 training or gaining experiences in the health-care settings.

160

161 **Study Selection and Data Extraction**

162 In this review, all the searched articles were imported into the EndNote version X⁴ software, and
163 after that, the duplicate articles were removed. Two investigators (BS and YT) independently
164 screened and identified articles by their titles, abstracts, and full-texts to determine eligibilities
165 against predetermined inclusion and exclusion criteria. Afterwards, the screened articles were
166 compiled together by the two investigators, and discrepancies were resolved through unanimous
167 consensus.

168 The data extraction form was prepared using Microsoft Excel Spreadsheet. Two reviewers
169 extracted data from the studies and were entered into Microsoft Excel. The data extraction form
170 included: (i) name of primary author; (ii) year of publication; (iii) region; (iv) sample size; (v)
171 study population; (vi) type of study design; (vii) sampling technique (viii) response rate and (ix);
172 12 months and lifetime prevalence of blood and body fluid exposure among HCWs.

173

174 **Quality Assessment**

175 The qualities of the appended studies were assessed and the risks for biases were judged using
176 the Joanna Briggs Institute (JBI) quality assessment tool for the prevalence studies [26]. There
177 were nine parameters: (1) appropriate sampling frame, (2) proper sampling technique, (3)
178 adequate sample size, (4) study subject and setting description, (5) sufficient data analysis, (6)
179 use of valid methods for the identified conditions, (7) valid measurement for all participants, (8)
180 using appropriate statistical analysis, and (9) adequate response rate (adequate if 60% or higher).
181 Failure to satisfy each parameter was scored as 1 if not 0. The risks for biases were classified as
182 either low (total score: 0 to 2), moderate (total score: 3 or 4), or high (total score: 5 to 9). Two
183 reviewers (BS and YT) assessed the quality of the studies included. Finally, articles with scores
184 of 5 to 9, which meant having a high risk of biases were debarred (**Appendices C**).

185

186 **Statistical Analysis**

187 Primarily, appended studies were categorized whether they have measured the lifetime
188 prevalence of blood and body fluid exposures or whether they are on a 12-month prevalence, and

189 later were entered into the STATA version 14. The meta pop program was utilized to estimate
190 the pooled prevalence of lifetime and 12-month prevalence of blood and body fluid exposure
191 among HCWs. Accordingly, the prevalence of blood and body fluid exposure (p) were estimated
192 using data from the appended studies which reported the proportion of HCWs whom were
193 exposed to body fluids at any time during their career, and twelve-month prevalence was
194 appraised using data from the studies which reported the proportion of participants exposed to
195 body fluids in the preceding 12 months. Corresponding standard errors (SE) were calculated
196 using $se = \sqrt{p(1 - p)/n}$. The researchers estimated the pooled prevalence of blood and body fluid
197 exposures using random-effects meta-analysis based on the DerSimonian and Laird approach.
198 The existence of heterogeneity among the studies was checked using the I^2 test statistics.
199 Heterogeneity will be classified into the following three categories: low heterogeneity (I^2 index <
200 25%), average heterogeneity (I^2 index= 25–75%), and high heterogeneity (I^2 index > 75%). Also,
201 a p-value of < 0.05 is used to declare heterogeneity. Thus, a random-effects model was used to
202 analyze data in this study, since the estimated both 12 months and lifetime prevalence of BBFs
203 was found to be high. Finally, Meta-regression analysis was used to evaluate the association
204 between the prevalence of BBFs and publication year, and sample size in the selected studies.

205

206 **Publication Bias**

207 In this meta-analysis, possible publication biases were visualized thru funnel plots. Symmetrical
208 large inverted funnels resembled the absence of publication biases. Also, the probability of
209 publication biases were tested using two main statistical methods (Egger's and Begg's tests)
210 which were wield to test funnel plot asymmetries. The level of significance for asymmetries
211 were viewed as $p < 0.05$.

212

213 **Sensitivity Analysis**

214 Also, sensitivity analyses were undertaken – the stability of the pooled estimate for each study.
215 The investigation was done by excluding a single individual study from the analysis at a time to
216 explore the robustness of the findings.

217

218

219 **Results**

220 **Description of the Studies**

221 The initial electronic searches generated 641 studies using international databases and Ethiopian
222 university research repositories. The database included PubMed (82), Science Direct (61), Hinari
223 (279), Google Scholar (196), Cochrane Library (1), and the remaining 22 studies were identified
224 through manual search. Of these, 151 duplicates were identified and effaced. From the tarry of
225 490 articles, based on the pre-defined eligibility criteria, 428 articles were excluded after reading
226 their titles and abstracts. 62 full-text articles remained and were further assessed for their
227 eligibilities. Finally, based on the pre-defined inclusion and exclusion criteria and quality
228 assessment, only 37 articles were extracted for the final analyses [10-14, 16-23, 27-50] (**Fig. 1**).

229

230 **Characteristics of the Appended Studies**

231 The general characteristics of the favored articles were presented in **Table 1**. Of the 37 articles
232 included in this review and meta-analyses, 14 were conducted in Addis Ababa; 10 in the Amhara
233 Region; 6 in Oromia Region; 4 from the Southern Nations, Nationalities, and People (SNNP); 2
234 in Harari Region; and only 1 from Tigray Region. A total number of 11,168 healthcare workers
235 participated in the study – the highest and lowest sample sizes were from the studies of
236 Geberemariam et al. [13] in the Oromia Region (648 HCWs), and [47] in Addis Ababa (104
237 HCWs). All the appended studies were cross-sectional studies. Twenty-three studies were
238 conducted solely among hospital healthcare workers. Among the studies, twenty-three of them
239 also presented data regarding 12-month prevalence on occupational exposures to BBFs [10-12,
240 14, 16, 17, 19-23, 27-29, 35, 37-39, 44-47, 49], and the lifetime prevalence on BBF exposures
241 were reported in twenty-six studies [11-15, 18-20, 22, 28-34, 36, 39-43, 45, 46, 48, 50]. From
242 the studies, thirteen articles have reported having both the 12-month and lifetime BBFs exposure
243 prevalence [10-12, 14, 19, 20, 22, 28, 29, 39, 44-46]. The latest article was published in 2020
244 [10], and the earliest study was concluded last 2007 [45]. The prevalence of 12 months BBFs
245 among the Ethiopian HCWs ranged from 16.5% [12] to 67.5% [23] in Addis Ababa Region. The
246 lifetime prevalence of BBFs varied from 28.8% in the Harari Region [14] to 81.0% in the
247 Amhara Region [33]. In this review, a low risk of bias was realized in 33 (89.2%) of the
248 included studies (**Appendices C**).

249

250 **Prevalence of Blood and Body Fluid Exposures among HCWs in Ethiopia**

251 The current meta-analysis using the random-effects model conveyed that the estimated overall
252 pooled prevalence of 12 months BBF exposures among HCWs in Ethiopia was 44.24% (95%CI:
253 36.98-51.51) with a significant level of heterogeneity ($I^2 = 97.9\%$; $p < 0.001$) (**Fig. 2**). The
254 lifetime pooled prevalence of BBFs using the random-effects model was 54.15% (95% CI 47.54-
255 60.75) with a significant level of heterogeneity ($I^2 = 97.6\%$; $p < 0.001$) (**Fig. 3**).

257 **Investigation of Heterogeneity and Subgroup Analysis**

258 The included studies in this meta-analysis exhibited a statistically significant heterogeneity
259 between studies ($I^2 = 97.9\%$; $p < 0.001$, and $I^2 = 97.6\%$; $p < 0.001$) for the 12-month and lifetime
260 BBF exposure prevalence estimates, respectively. Accordingly, the random-effects model was
261 used to adjust the observed variability. In identifying the possible source of heterogeneity,
262 subgroup analyses were utilized based on the geographical regions, type of healthcare facilities,
263 year of publication, and sample size. However, the level of heterogeneity between studies
264 remained high after subgroup analysis (**Table 2**).

265 The prevalence of 12 months BBFs was found to be higher in the Tigray Region 60.20 %
266 (95%CI: 55.83-64.57) and the least was reported from the Harari Region 31.86% (95%CI: 8.73-
267 54.98). This meta-analysis also found that the lifetime prevalence of BBF exposures differed
268 between various regions, and the highest prevalence was found in the Amhara Region, 60.83%
269 (95%CI: 47.03-74.62), followed by SNNP Region, 54.35% (95%CI: 28.38-80.31), and finally,
270 the least in Harari Region, 20.80% (95%CI: 24.76-32.83). Withal, the 12 months and lifetime
271 prevalence of BBF exposures were 41.04 (95%CI: 30.63-51.45) and 56.56% (95%CI: 49.44-
272 63.68) in studies published between 2015 and 2020, respectively (**Table 2**).

274 **Sensitivity Analysis**

275 To identify the source of heterogeneity and to explore the robustness of the findings, a leave-one-
276 out sensitivity analysis was employed. The result of sensitivity analyses using the random-effects
277 model revealed that no single study influenced the overall prevalence of 12 months and lifetime
278 BBF exposures among HCWs (**Appendices D**).

279
280

281 **The Publication Bias**

282 The presence of publication bias was evaluated using funnel plots and Egger's tests at a
283 significance level of less than 0.05. The findings revealed that publication bias was not
284 significant for the studies reported in the 12-month prevalence of BBF exposures ($p = 0.05$) (**Fig.**
285 **4**). In the same manner, it was not statistically significant ($p = 0.92$) for the lifetime BBFs
286 exposures, as well (**Fig. 5**).

287

288 **Meta-Regression Analysis**

289 The results of the meta-regression analysis showed that the publication year and the sample size
290 were not significant sources of heterogeneity. In this study, no significant relationship were
291 identified between the 12 month prevalence of BBFs and publication year (p -value=0.76), and
292 sample size (p -value= 0.44). Similarly, there was no significant association between the lifetime
293 prevalence of BBFs and publication year (p -value=0.42) and sample size (p -value= 0.48) (**Table**
294 **3**).

295

296 Discussion

297 Each year, hundreds of thousands of HCWs, including waste handlers, face the risk of blood-
298 borne diseases due to occupational BBF exposures [3, 8, 9, 51]. In Ethiopia, despite the
299 recognition on the importance of HBV, HCV, HIV, and other diseases transmitted through BBFs
300 by the Federal Ministry of Health (FMOH), currently, there is dearth of systematic reviews and
301 meta-analyses that estimated the prevalence of BBFs exposure among HCWs. In this reckon, this
302 study was the first systematic review and meta-analysis that aimed to estimate lifetime and a 12-
303 month prevalence on occupational exposure to BBFs among Ethiopian HCWs. This review
304 involved the results of 37 articles which investigated the prevalence of BBF exposures, and a
305 high burden on occupational exposures to BBFs among HCWs in Ethiopia was evidently
306 identified.

307 The estimated pooled 12- month and lifetime prevalence on BBF exposures among HCWs in
308 Ethiopia were 44.2% and 54.2%, respectively. Forbye, the 12- month BBFs prevalence in the
309 primary studies ranged from 16.5% [12] to 67.5% [23]. In parallel, the lifetime prevalence
310 ranged from 28.8% [14] and 81.0% [33]. This 12-month pooled prevalence estimate was almost
311 comparable from the pooled estimate from East Africa (47.3%) [9], Côte d'Ivoire, Mali and
312 Senegal (45.7%) [52], and a study by Bi P et from Australia, revealed that 42% of HCWs had
313 body fluid exposures in a year on their study [53]. However, it was lower than the studies
314 conducted in Turkey (57%) [54] and Nigeria 67.5% [55]. These differences might be subjected
315 to the variances in the socio-demographic, cultural characteristics of study participants, and study
316 health facility setup variations.

317 This study explicated a higher prevalence of lifetime BBF exposures (54.2%), however, it was
318 subservient than the reviews from the 65 studies in 21 African countries (65.7%) [9]. The
319 foremost reason for this variation may be due to study setting dissimilarities. This finding is also
320 inconsistent with a study in Iran which reported the prevalence of exposures at 46.47% [56]. The
321 variance could be due to the discrepancies in the study participants, the type of healthcare
322 facilities, and socio-demographic factors.

323 In this review, the researchers identified a variation in the HCWs' exposure to BBFs across the
324 Ethiopian regions. The lifetime (60.83% in Amhara Region) and 12 months (60.20% in Tigray
325 Region and 48.69% in Amhara Region) occupational exposure to BBFs were consistently more
326 frequent in Northern Ethiopia, and less in Harari Region (lifetime prevalence of 28.80% and 12-

327 month prevalence of 31.86%). The probable rationale for these regional variations may be due
328 to: the number of studies included; type of healthcare facilities; and geographical and
329 demographical differences. The other possible vindication for these disparities may be partially
330 explained by the polarities in the levels of standard precaution practices among the HCWs in the
331 various regions. As one study reported, 80.8% of the HCWs regularly follow standard
332 precautions in Eastern Ethiopia, including the Harari Region [14].

333 A laudative prevalence of BBF exposures among HCWs working exclusively in hospitals than
334 those in the health centers (primary healthcare units) was also found. Almost half of the HCWs
335 working in hospitals of Ethiopia had at least one BBFs exposure in their lifetime and in the last
336 12 months. The finding was predictable because these HCWs had higher workloads and they
337 performed further medical procedures, which may have exposed them to occupational BBFs
338 compared to those in the health centers. Therewithal, the high prevalence of BBF exposures
339 among HCWs working in the hospitals had significant implications because most of the blood-
340 borne viruses, such as HCV, HBV, and HIV, may haply spread through BBFs exposures,
341 therefore, enhancing HCWs' compliance towards standard precautionary measures is deemed
342 necessary.

343

344 **Limitations**

345 This review article had a few adversities due to its limitations. One of which was the cross-
346 sectional design nature of the included studies and all were based on self-reported data whilst
347 estimating the prevalence of occupational BBFs exposures. Additionally, social desirability and
348 recall biases were likely present. Since the study was conducted in Ethiopia, included healthcare
349 facilities and the generalization of the study findings was limited to these similar contexts.
350 Further, there was no study obtained from the some Ethiopian regions, such as Afar Regional
351 State and Benshangul-Gumuz Regional State and this might probably affect the generalizability
352 of the present findings at a national level.

353 **Conclusions**

354 This review exhibited a higher percentage of occupational exposures to BBFs among HCWs in
355 Ethiopia. The available evidences suggest that more than two-in-five and one-half of healthcare
356 workers in Ethiopia were exposed to BBFs annually and in their lifetime, respectively.

357 Therefore, efforts should be implemented to reduce the high burden of occupational blood and
358 body fluid exposures through effective implementation of standard precaution measures along
359 with aggressive occupational health and safety activities.

370 **Availability of supporting data**

371 All relevant data are within the manuscript and its supporting information files.

372 **Competing interests**

373 The author declares that he has no competing interests.

374 **Funding**

375 No fund was received for the present review.

376 **Authors' Contribution**

377 BS: Conceptualizes, design the study and data curation, performed the analysis, wrote and
378 approved the final manuscript. YT: Data curation and performed the analysis, and approved the
379 final manuscript DW: Contribute to the analysis, critically reviewed the manuscript and

380 approved the final manuscript. BJ: critically revised the manuscript and approved the final
381 manuscript. All authors read and approved the final manuscript before submission.

382 **Acknowledgments**

383 The authors acknowledge Madda Walabu University, College of Health Sciences staff for their
384 support during this research work.
