25 dimissione ospedaliera).

26

27

28 **Abstract**

29

30 **Background**

31 Some experts recently reported that SARS-CoV-2 lethality decreased considerably, but no evidence is yet
32 available. This retrospective cohort study aimed to evaluate whether SARS-CoV-2 case-fatality rate
33 decreased with time, adjusting for main potential confounders.

34 **Methods and findings**

35 We included all SARS-CoV-2 infected subjects diagnosed in Ferrara and Pescara provinces, Italy.
36 Information were collected from local registries, clinical charts, and electronic health records. We compared
37 the case-fatality rate of the subjects diagnosed during April and March, 2020. We used Cox proportional
38 hazards analysis and random-effect logistic regression, adjusting for age, gender, hypertension, type II
39 diabetes, major cardiovascular diseases (CVD), chronic obstructive pulmonary diseases (COPD), cancer and
40 renal disease. The sample included 1946 subjects (mean age 58.8y; 45.7% males). 177 persons deceased,
41 after a mean of 11.7 days of follow-up. From March to April, the case-fatality rate significantly decreased in
42 the total sample (10.8% versus 6.0%; $p < 0.001$), and in any subgroup of patients. Large reductions of the
43 lethality were observed among the elderly (from 30.0% to 13.4%), and subjects with hypertension (23.0% to
44 12.1%), diabetes (30.3% to 8.4%), CVD (31.5% to 12.1%), COPD (29.7% to 11.4%), and renal disease
45 (32.3% to 11.5%). In April, the adjusted hazard ratio of death was 0.42 (95% Confidence Interval: 0.29-
46 0.60). The mean age of those who died substantially increased from March ($77.9 \pm 10.8y$) to April
47 ($86.9 \pm 7.7y$).

48 **Conclusions**

49 In this sample, SARS-CoV-2 case-fatality rate decreased considerably over time, supporting recent claims of
50 a substantial improvement of SARS-CoV-2 clinical management. The findings are inevitably preliminary
51 and require confirmation.

52

53

54 **Author summary**

55

56 **Why was this study done?**

- 57 • Some experts recently reported that SARS-CoV-2 lethality decreased considerably, but no evidence
58 is yet available.

59

60 **What did the researchers do and find?**

- 61 • We carried out a retrospective cohort study on 1946 SARS-CoV-2 infected subjects from two Italian
62 provinces, evaluating the potential variation of the case-fatality rate over time.
- 63 • From March to April, in both univariate and multivariable analyses, SARS-CoV-2 case-fatality rate
64 significantly and substantially decreased, overall and in any subgroup of subjects.

65

66 **What do these findings mean?**

- 67 • The therapies and clinical management of SARS-CoV-2 infected subjects might have substantially
68 improved over time.

69

70

71

72 **Introduction**

73 As of May 18, 2020, SARS-CoV-2 pandemic has caused 320,000 deaths worldwide [1], with largely
74 discrepant case-fatality rates across countries (from <1% to 16%) [2], likely due to differences in population
75 age structure [3, 4], variations in testing policies and case recording [5], and/or preparedness of the
76 healthcare system, which in turn is affected by the intensity of the spread [4, 5].

77 Since the start of the pandemic, Italy has been among the countries with the highest death toll, with more
78 than 32,000 recorded deaths [1], and an estimated case-fatality rate of 14% [2], which peaked at 20% among
79 the citizens aged ≥ 80 years [6].

80 In the last few weeks, some clinicians suggested that SARS-CoV-2 lethality decreased considerably, mostly
81 as a consequence of more tailored therapeutic approaches [7-11]. Although the claims were made by expert
82 physicians, actively engaged in the care of infected patients, the available evidence is anecdotal or based
83 upon case-studies.

84 We analysed the data of all infected cases in two Italian Provinces to evaluate whether SARS-CoV-2 case-
85 fatality rate decreased with time, adjusting for main potential confounders.

86

87 **Methods**

88 This retrospective cohort study included all subjects infected with SARS-CoV-2, diagnosed in the Provinces
89 of Ferrara and Pescara, between March 3 (the onset date of the first cases), and April 25, 2020. All
90 participants were followed up to May 5, 2020. All infections were diagnosed by the central laboratories of
91 Ferrara University Hospital or Pescara Hospital through RT-PCR (Reverse transcription polymerase chain
92 reaction) test on nasopharyngeal swabs, and were confirmed by the Italian National Institute of Health.
93 Information on age, gender, and pre-existing conditions of all participants were collected from local
94 registries, clinical charts (for hospitalized patients), and through data-linkage with hospital discharge
95 abstracts (Italian SDO) and the National database of drug prescription. Electronic databases were queried
96 from the day of the diagnosis until January 1st, 2015. All data have been revised manually by two physicians
97 (LM and MEF), and the following conditions have been included in the analyses: hypertension, type II

98 diabetes, major cardiovascular diseases (heart failure, myocardial infarction and stroke - CVD), chronic
99 obstructive pulmonary diseases (COPD, bronchitis, pneumonia, asthma, and emphysema), malignant tumors
100 and renal disease.

101 The study complies with the Declaration of Helsinki, the research protocol was approved by the Ethics
102 Committee of the Emilia-Romagna Region (code 287, approved on March 24, 2020), and the requirement for
103 informed consent was waived because of the retrospective and pseudo-anonymized nature of the data.

104

105 **Data Analysis**

106 We compared the case-fatality rate (fatal / confirmed cases) during the first 29 days after the index day (from
107 March 3 to March 31) with that of the second half of the period (days 30-53; from April 1 to April 25). The
108 differences between the two periods were initially evaluated using t-test for continuous variables, and chi-
109 squared test for categorical ones. The potential independent predictors of death were then evaluated using
110 Cox proportional hazards analysis (using the data censored at May 5, to include ≥ 10 days of follow-up). All
111 covariates were included a priori in the model in their original form, with the exception of age, which was
112 treated as either continuous or ordinal, to explore the association between the outcome and several age
113 classes. Schoenfeld's test was used to assess the validity of proportional hazards assumption, and Nelson-
114 Aalen cumulative hazard estimates to check the validity of constant incidence ratios during the follow-up
115 [12]. Using the data censored at 20 days of follow-up, a random-effect logistic regression was also fit, with
116 province as the cluster unit. The same above criteria were used to build the final model. Missing data were
117 $< 5\%$ in all primary analyses; therefore, no missing imputation technique was adopted. Statistical significance
118 was defined as a two-sided p -value < 0.05 , and all analyses were carried out using Stata, version 13.1 (Stata
119 Corp., College Station, TX, 2014).

120

121 **Results**

122 The sample consisted of 1946 subjects (mean age 58.8y; 45.7% males); of them, 31.2% were hypertensive,
123 12.3% diabetics, and 16.6% with CVD. Some of the characteristics of the sample significantly varied from
124 March to April. Infected subjects were older by 5.6 years, and the proportion of females, diabetics, subjects
125 with CVD and renal diseases significantly increased (Table 1).

126

127 **Table 1. Characteristics of the sample, overall and by time of SARS-CoV-2 infection**
 128 **diagnosis after the first case (March 3, 2020).**

	Total sample (n=1946)	March 2020 ^a (n=1244)	April 2020 ^b (n=702)	p*
Mean age (SD), years	58.8 (21.3)	56.8 (20.0)	62.4 (23.0)	<0.001

Cancer, %	7.7	8.3	6.6	0.2
Renal diseases, %	5.9	5.0	7.4	0.029

129

130 ^a From March 3 to March 31.

131 ^b From April 1 to April 25.

132 * Chi-squared test for categorical variables, t-test for continuous ones.

133

134 Overall, 177 persons deceased (after a mean of 11.7 days of follow-up): 135 of the 1244 subjects diagnosed
 135 in March, 42 of the 702 subjects diagnosed in April. The mean age of those who died substantially increased:
 136 it was 77.9±10.8 for those diagnosed in March, 86.9±7.7 for those detected in April (p<0.001). In March, 28
 137 of those deceased were younger than 70 years, and 8 were younger than 60 years. In April, a single death
 138 occurred in subjects younger than 70 years.

139 From March to April, the overall case-fatality rate significantly decreased (10.8% versus 6.0%, respectively;
 140 p<0.001 - Fig 1).

141

142 **Figure 1. SARS-CoV-2 case-fatality rate in the first two months of the pandemic (March and April,**
 143 **2020), overall and stratified for the most frequent risk classes (all $p < 0.05$). Vertical bars are referred**
 144 **to 95% confidence intervals.**

145

146 As shown in Table 2, a reduction of SARS-CoV-2 lethality was observed in any age-class and any category
 147 of risk. The decrease was however larger among the subjects at higher risk of death: with the lethality
 148 dropping from 23.4% to 6.1% in the age-class 70-79y, and from 36.3% to 16.1% among the elderly (80+
 149 years); both $p < 0.05$. Similar reductions of the case-fatality rate were observed among the subjects with
 150 hypertension (from 23.0% to 12.1%), diabetes (from 30.3% to 8.4%), CVD (from 31.5% to 12.1%), COPD
 151 (from 29.7% to 11.4%), and renal disease (from 32.3% to 11.5%; all univariate p -values < 0.05).

152

153 **Table 2. Proportion of deaths, overall and by time of SARS-CoV-2 infection diagnosis after**
 154 **the first case (March 3, 2020), and hazard ratios (HRs) predicting the time to death of patients**
 155 **diagnosed in April vs March 2020.**

156

157 ^a From March 3 to March 31.

158 ^b From April 1 to April 25.

159 ^c Chi-squared test for categorical variables, t-test for continuous ones.

160 ^d Cox proportional hazard model, adjusted for age, gender, hypertension, diabetes, major cardiovascular
161 diseases, COPD, cancer and renal disease. Some models could not be fit due to the scarce number of deaths.

162

163 Cox analysis substantially confirmed univariate results: adjusting for age, gender, hypertension, diabetes,
164 CVD, COPD, cancer and renal disease, the hazard ratio (HR) of death of those diagnosed in April, as
165 compared to March, was 0.42 (95% Confidence Interval - CI: 0.29-0.60 - Table 2). With the only exception
166 of the subjects with history of cancer, a significantly, considerably lower likelihood of death was observed in
167 any subset of the sample, with HRs ranging from 0.20 among the subjects with renal disease, up to 0.51
168 among those aged 80 years or more (Table 2). The results of the random-effect logistic regression did not
169 vary: overall, the adjusted odds ratio of death at 20 days was 0.29 (95% CI: 0.19-0.45; $p < 0.001$) for those
170 diagnosed in April, as compared to the subjects detected in March.

171

172 **Discussion**

173 This study provides the first evidence of a considerable decrease of SARS-CoV-2 case-fatality rate over
174 time. From March to April 2020, the death rate decreased by more than 50% in all age-classes, being larger
175 among the subjects with the highest risk of death because of comorbidities [13, 14]. This finding was
176 confirmed in all multivariable analyses, adjusting for several potential confounders.

177 It is complex to discern which could be the potential reasons for the observed, entirely novel findings. The
178 first, most obvious explanation, is that the healthcare system might have been overcrowded during the
179 epidemic peak in March, with a loss of efficacy [15]. This is however very unlikely to apply to the present
180 sample, because SARS-CoV-2 infection rates were relatively low - and never exceeded the capacity of the
181 intensive care units - in the two provinces under analysis [16].

182 Other potential, non mutually exclusive explanations include virus mutation and substantial improvements in
183 the organization (including the expansion of dedicated hospital beds), therapy and management of the
184 infected subjects. Some scientists suggested that a less virulent viral strain, with consequent reduced
185 lethality, might emerge during the pandemic [10]. Alternatively, the infection might have accelerated the
186 clinical path of the most fragile individuals in the earlier phases. Both hypotheses, however, are currently
187 unsubstantiated by data [17]. Concerning the therapy, a growing number of clinicians suggest that the current
188 therapeutic approach, based upon the early administration of more tailored medications, is considerably
189 improving the clinical course of COVID-19 [7-9, 11]. In the two provinces under investigation, the treatment
190 is currently based upon antiviral agents (lopinavir / ritonavir), intensive respiratory support [18, 19], and,
191 from the latest days of March, low molecular weight heparin and monoclonal antibodies against
192 inflammatory cytokines (e.g. tocilizumab), which showed some preliminary, promising results [18, 20-23].
193 Given that available data are anecdotal, and no therapeutics is currently recommended for or against SARS-
194 CoV-2 infection or disease [24], only the results of the several randomized trials that are being conducted on
195 the above treatments [18, 25], will permit to discern which approach, and to what extent, contributed to the
196 improvement of SARS-CoV-2 infection prognosis.

197 The main limitations of the study are the inclusion of only two provinces from a single country, and the lack
198 of data on body mass index, which is emerging as significant predictor of death from COVID-19 [26, 27].

199 In conclusion, the present study provided evidence of a significant, considerable decrease of SARS-CoV-2
200 case-fatality rate between March and April, 2020, supporting preliminary claims on a substantial
201 improvement of the therapeutic approaches. The findings are inevitably preliminary and require confirmation
202 from further datasets and ongoing randomized trials.
