Abstract

We formulate a deterministic epidemic model to study the effects of medication on the transmission dynamics of Corona Virus Disease (COVID-19). We are especially interested in how the availability of medication could change the necessary quarantine measures for effective control of the disease. We model the transmission by extending the SEIR model to include asymptomatic, quarantined, isolated and medicated population compartments. We calculate the basic reproduction number R_0 and show that for $R_0 < 1$ the disease dies out and for $R_0 > 1$ the disease is endemic. Using sensitivity analysis we establish that R_0 is most sensitive to the rates of quarantine and medication. We also study how the effectiveness and the rate of medication along with the quarantine rate affect R_0 . We devise optimal quarantine, medication and isolation strategies, noting that availability of medication reduces the duration and severity of the lock-down needed for effective disease control. Our study also reinforces the idea that with the availability of medication, while the severity of the lock downs can be eased over time some social distancing protocols need to be observed, at least till a vaccine is found. We also analyze the COVID-19 outbreak data for four different countries, in two of these, India and Pakistan the curve is still rising, and in the other two, Italy and Spain, the epidemic curve is now falling due to effective quarantine measures. We provide estimates of R_0 and the proportion of asymptomatic individuals in the population for these countries.

Keywords— COVID-19, Coronavirus, Medication, Quarantine, Asymptomatic, Control Strategies, Estimating R_0

1 Introduction

Originating in Wuhan, China, with the first reported cases in early December 2019[2], Coronavirus disease (COVID-19) is a pandemic that has spread around the globe in the early months of 2020. The disease is prevalent in at least 212 countries and territories, with more than 5.3 million cases reported and around 325,000 fatalities at the time of writing on May 22, 2020 [3].

The causative agent of COVID-19 is a coronavirus SARS-CoV-2 [2]. This belongs to a family of viruses that are found in humans and different species of animals including cattle, camels and bats. These have in the past caused serious disease outbreaks in human populations as happened in MERS (caused by MERS-CoV) and SARS (caused by SARS-CoV) [1, 4, 5], it has been reported that both these viruses like SARS-CoV-2 have their origins in bats.

The virus is mainly spread from person to person, through respiratory droplets, the spread is more likely when people are within 6 feet of each other[1]. Symptoms of the disease may appear 2-14 days after exposure and may include fever, cough shortness of breath, chills, muscle pain and loss of taste or smell[2, 6]. Many of these are common with influenza, however high persistent fever, dry cough and difficulty in breathing [6] seem to characterize COVID-19. The symptoms may range from very mild (in 80 % of the cases) to severe (in 15 % of the cases) to critical (in 5 % of the cases)[2]. Those at higher risk for severe illness include the elderly (people ages 65 and above) and people with underlying medical conditions which may include chronic lung diseases, diabetes, chronic kidney diseases, serious heart conditions and immunocompromised individuals[14].

At this time there is no available vaccine for COVID-19, and the available antiviral treatments are all in the trial phase[1]. This prompted health authorities to stress upon social distancing as a means to control the spread of the disease [2]. Lock downs were enforced in various countries, however these measures have resulted in substantial economic and social cost [7]. As a consequence many countries have started to ease the lock downs, despite concerns expressed by public health practitioners. There may be some positive news as in some recent studies antiviral treatments have shown some promising results, reducing the infectious period and alleviating disease symptoms [9, 8, 12, 13].

As the disease burden of COVID-19 continues to rise steeply, there is a rush to verify the benefits of different treatment regimens for which there is any anecdotal evidence available. Initial clinical trials so far have produced mixed results with some drug regimens showing encouraging outcomes, such as shortening of the duration of the disease, while others showing no significant change in the outcomes due to medication. The anti malarial hydroxychloroquine has been suggested as possible medication for COVID-19. While the National Institute of Health (NIH) in the United States has began clinical trials for hydroxychloroquine taken together with azithromycin [15], a recent study by Mehra et.al [10] has been unable to confirm any benefit of hydroxychloroquine when used alone or with a macrolide (such as Azithromycin), on in-hospital outcomes for COVID-19, in fact, each of these drug regimens was associated with decreased in-hospital survival. Another drug that has been suggested to have beneficial effects in COVID-19 treatment is Remdesivir. Some initial studies on the effectiveness of Remdesivir have been published; Wang et.al [11] reported no significant clinical improvement in COVID-19 symptoms using the drug, they do recommend further clinical studies be done, however Grein et.al [13] have reported improvement in 68% of the patients in a controlled trial using the drug, similarly Beigel et.al [9] have also reported shortening in the time to recovery with Remdesivir use. Huang et.al [6] used a triple anti viral therapy in their study and have reported alleviation of symptoms and shortening the duration of the disease. At the time of writing several studies are being carried out for a variety of plausible treatments which have shown some positive results. Based on this one can be cautiously optimistic about the possibility that medication that alleviates symptoms and shortens the duration of the disease may be available soon.

Since the outbreak many mathematical models have been proposed to estimate the growth rates and understand the transmission dynamics of COVID-19. These include phenomenological models[16, 17], stochastic models[18], both of which are very useful in the early stages of the outbreak, and mechanistic models[19, 20, 22, 23, 30] that incorporate our understanding of the transmission pathways. Imran et.al [24] and Perkins et.al [31] have used optimal control techniques to propose efficient control strategies. The aim of such modeling is twofold, one to provide estimates of the severity of the outbreak by calculating quantities like the growth trends of the epidemic, estimates of the final outbreak size and duration of the outbreak and second to provide insights into efficacy of various control measures.

In the literature a variety of mathematical models have been proposed to study the role of medication in controlling different epidemics. Lee et.al [25] consider an extension of the SEIR model with isolation and treatment to study various treatment and isolation strategies for controlling an influenza pandemic. Granich et.al [27] use an SIR model with multiple infection and treatment stages to study the effects of antiretroviral therapy and universal

voluntary reporting for HIV. Jia et.al [26] study the effectiveness of various control strategies including treatment using an SEIR model with compartments for acute and chronic stages of infection and treatment. Sharomi et.al [28] use an extension for the SEIR model to study HIV/TB co-infection and do a cost/benefit analysis of various treatment strategies. Tufail et.al [29] study a model for the transmission and control of the H1N1 Influenza (Swine Flu) using an extended SEIR model with treatment, vaccination and hospitalization compartments.

This study is motivated by some promising reports about the success of various drug therapies in medical trials as discussed above. We are interested in studying the effects of medication on the transmission dynamics of COVID-19 and in particular the effects on quarantine and other control strategies. We extend an earlier model by Imran et.al [24] to model the transmission dynamics of COVID-19. The model incorporates asymptomatic, isolation and quarantine compartments, these are considered particularly relevant in the transmission of COVID-19, we also include a compartment representing the medicated population group. We establish a threshold quantity, the basic reproductive number R_0 , the disease dies out if $R_0 < 1$ and is endemic in the population when $R_0 > 1$. We calculate the sensitivity of R_0 on various model parameters, identifying the contact rate, the rates of entering and leaving the quarantine and the rate and efficacy of the medication, as parameters to which R_0 is most sensitive. We also study the variation in R_0 as the quarantine rate and the rate and the efficacy of the medication is varied, leading to some interesting observations. Using techniques from optimal control theory, we propose efficient quarantine, isolation and medication strategies. We also compare the quarantine and isolation strategies with and without the availability of medication, which leads to some insights regarding easing of lock downs once medication is available. Finally, we estimate R_0 for different countries, which are at different phases of the epidemic. In India and Pakistan the epidemic is still in the growth phase, the dynamics of the disease also seem to be different here than in Europe and North America, with a much slower growth and mortality rate. We also fit our model to the outbreak data to estimate the proportion of asymptomatics in the population and the average quarantine rate in these countries.

2 Model Formulation

The COVID-19 transmission model we consider is based upon the SEIR model and takes into account the effects of quarantine, isolation, medication and asymptomatic individuals. The total population $N(t)$ is divided into ten mutually exclusive sub populations, susceptibles S , these are individuals who can fall ill by coming in contact with an infected individual, quarantined susceptibles Q_S , these individuals are removed from the susceptible group at rate ϵ , either through self quarantined or lock-down measures, they however go back to the susceptible group at rate ξ . The susceptibles move to the exposed class by coming in contact with any infectious individual, at rate $\rho\lambda$, some exposed individuals will not show symptoms and are accounted for in the model by the movement to the asymptomatic class at rate $(1 - \rho)\lambda$. Due to lock down measures, the exposed and asymptomatic sub-populations are also quarantined at rate κ_E and κ_A , respectively. The exposed and exposed quarantined individuals become infected at rates σ and ν , while some of the quarantined exposed are also isolated at the rate of ω_E . Infected individuals can be isolated or given medication at a rate of τ and α_I whereas a fraction of isolated are given medication at rate α_Q . The recovery time for infected, asymptomatic, asymptomatic quarantined, isolation and medication is given by $1/\gamma, 1/\theta_A, 1/\omega_A, 1/\theta$ and $1/\theta_M$ respectively. The schematic of the transmission pathways is given in Fig.1. The total population $N(t)$ is given by the sum of the sub-populations.

$$N(t) = S(t) + Q_S(t) + E(t) + Q_E(t) + I(t) + A(t) + Q_A(t) + Q_I(t) + M(t) + R(t) \quad (1)$$

The governing equations are given below (2).

$$\begin{aligned}
 \frac{dS}{dt} &= \Pi + \xi Q_S - (\lambda + \mu + \epsilon)S \\
 \frac{dQ_S}{dt} &= \epsilon S - (\xi + \mu)Q_S \\
 \frac{dE}{dt} &= \rho \lambda S - (\kappa_E + \sigma + \mu)E \\
 \frac{dQ_E}{dt} &= \kappa_E E - (\omega_E + \nu + \mu)Q_E \\
 \frac{dI}{dt} &= \sigma E + \nu Q_E - (\delta_I + \tau + \alpha_I + \mu + \gamma)I \\
 \frac{dA}{dt} &= (1 - \rho)\lambda S - (\kappa_A + \theta_A + \mu)A \\
 \frac{dQ_A}{dt} &= \kappa_A A - (\omega_A + \mu)Q_A \\
 \frac{dQ_I}{dt} &= \tau I + \omega_E Q_E - (\theta + \alpha_Q + \delta_Q + \mu)Q_I \\
 \frac{dM}{dt} &= \alpha_I I + \alpha_Q Q_I - (\theta_M + \mu)M \\
 \frac{dR}{dt} &= \theta Q_I + \gamma I + \theta_A A + \omega_A Q_A + \theta_M M - \mu R
 \end{aligned} \tag{2}$$

where λ is the force of infection

$$\lambda = \frac{\beta}{N} (I + \eta_1 Q_I + \eta_2 A + \eta_3 Q_A + \eta_4 M) \tag{3}$$

Here β is the effective contact rate, where as η_1, η_2 and η_3 are the associated relative infectiousness parameters for the Q_I, A, Q_A and M sub-populations. Table.3 and Table.4 represent the description of variables and parameters of the model, and are given in the appendix.

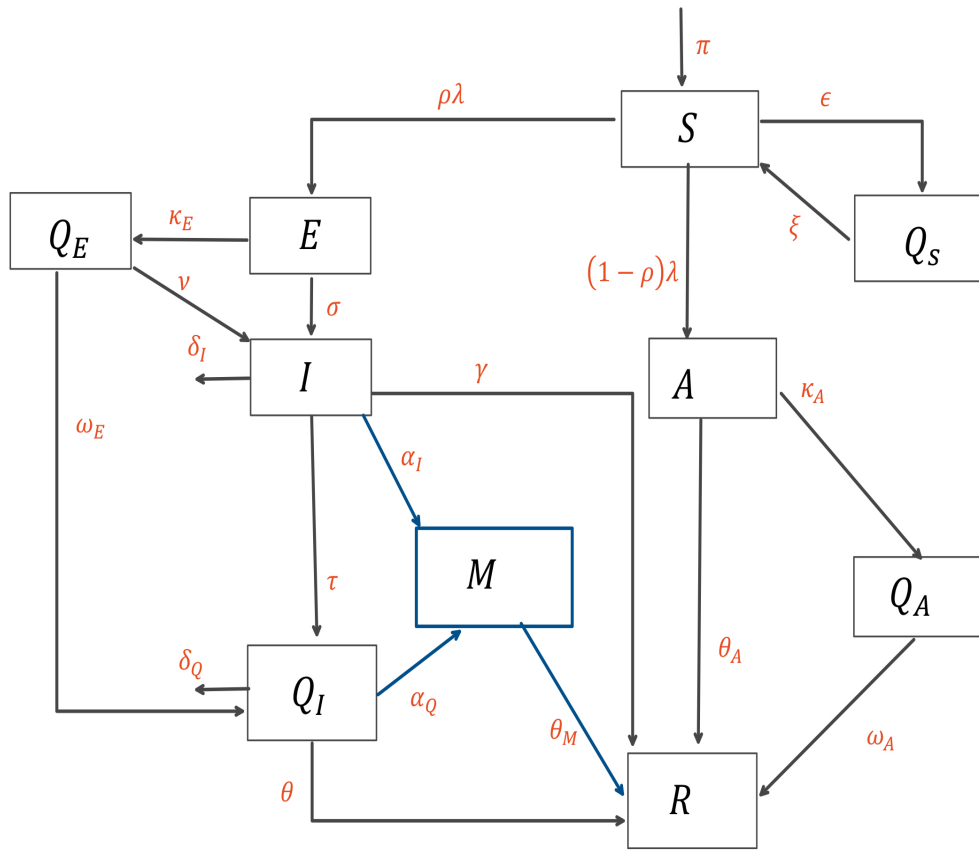

Figure 1: Schematic diagram of the model (2)

3 Basic Properties

The described state variables in model (2) display non-negative solutions for all time $t \geq 0$ for non-negative initial conditions.

Lemma 3.1. *For any given non-negative initial conditions, there exist a unique solution $S, Q_S, E, Q_E, I, A, Q_A, Q_I, M, R$ respectively, for all $t \geq 0$. Moreover, it satisfy the following inequality of boundedness.*

$$\limsup_{t \rightarrow \infty} N(t) \leq \frac{\Pi}{\mu}$$

Proof is presented in the appendix A.

Lemma 3.2. *The closed set:*

$$\mathcal{D} = \{(S, Q_S, E, Q_E, I, A, Q_A, Q_I, M, R) \in \mathbb{R}_+^{10} : S + Q_S + E + Q_E + I + A + Q_A + Q_I + M + R \leq \frac{\Pi}{\mu}\}$$

is positively invariant.

Proof is attached in the appendix A.

4 Steady State Analysis

4.1 Disease Free Equilibrium

The transmission model (2) attains the Disease Free Equilibrium (DFE) whenever there is no infection induced by the disease i.e. the force of infection is zero, $\lambda = 0$. Mathematically we can find this equilibrium state by equating the right hand side of (2) to zero with zero force of infection. Let \mathcal{F}_0 represent the DFE of the model.

$$\mathcal{F}_0 = (S^*, Q_S^*, E^*, Q_E^*, I^*, A^*, Q_A^*, Q_I^*, M^*, R^*)$$

$$\mathcal{F}_0 = \left(\frac{\pi(\mu + \xi)}{\mu(\mu + \xi + \epsilon)}, \frac{\pi\epsilon}{\mu(\mu + \xi + \epsilon)}, 0, 0, 0, 0, 0, 0, 0 \right)$$

The local stability of this steady state is governed by the threshold quantity \mathcal{R}_0 which is obtained using the next generation operator method [32].

4.2 The Basic Reproduction Number \mathcal{R}_0

The threshold quantity \mathcal{R} represents the average number of secondary infections generated by the single infection in the completely susceptible population. It is determined by the spectral radius of the FV^{-1} matrix. [32]. The corresponding F and V matrices of model (2) are given as

$$F = \begin{pmatrix} 0 & 0 & \frac{\beta\rho S^*}{N^*} & \frac{\beta\rho\eta_2 S^*}{N^*} & \frac{\beta\rho\eta_3 S^*}{N^*} & \frac{\beta\rho\eta_1 S^*}{N^*} & \frac{\beta\rho\eta_4 S^*}{N^*} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{\beta(1-\rho)S^*}{N^*} & \frac{\beta(1-\rho)\eta_2 S^*}{N^*} & \frac{\beta(1-\rho)\eta_3 S^*}{N^*} & \frac{\beta(1-\rho)\eta_1 S^*}{N^*} & \frac{\beta(1-\rho)\eta_4 S^*}{N^*} \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & 0 & 0 & 0 & 0 \end{pmatrix}$$

$$V = \begin{pmatrix} k_1 & 0 & 0 & 0 & 0 & 0 & 0 \\ -\kappa_E & k_2 & 0 & 0 & 0 & 0 & 0 \\ -\sigma & -\nu & k_3 & 0 & 0 & 0 & 0 \\ 0 & 0 & 0 & k_4 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\kappa_A & k_5 & 0 & 0 \\ 0 & -\omega_E & -\tau & 0 & 0 & k_6 & 0 \\ 0 & 0 & -\alpha_I & 0 & 0 & -\alpha_Q & k_7 \end{pmatrix}$$

where $k_1 = \kappa_E + \sigma + \mu$, $k_2 = \omega_E + \nu + \mu$, $k_3 = \delta_I + \tau + \gamma + \alpha_I + \mu$, $k_4 = \kappa_A + \theta_A + \mu$, $k_5 = \omega_A + \mu$, $k_6 = \theta + \delta_Q + \alpha_Q + \mu$, $k_7 = \theta_M + \mu$

$$\mathcal{R}_0 = \frac{\beta(\mu + \xi)}{\mu + \xi + \epsilon} \left\{ (1 - \rho) \left(\frac{\eta_3 \kappa_A}{k_4 k_5} + \frac{\eta_2}{k_4} \right) + \rho \left[\left(\frac{\nu \kappa_E}{k_1 k_2 k_3} + \frac{\sigma}{k_1 k_3} \right) \left(\frac{\eta_4 \alpha_I}{k_7} + \frac{\eta_1 \tau}{k_6} + \frac{\eta_4 \tau \alpha_Q}{k_6 k_7} + 1 \right) + \frac{\kappa_e \omega_E (\eta_1 k_7 + \eta_4 \alpha_Q)}{k_1 k_2 k_6 k_7} \right] \right\} \quad (4)$$

Stability of DFE

Lemma 4.1. *The steady state (DFE) \mathcal{F}_0 of the model (2) is locally-asymptotically stable if $\mathcal{R}_0 < 1$, and unstable if $\mathcal{R}_0 > 1$.*

The basic interpretation of this lemma is that a small influx of the infected individuals will not cause large outbreaks and disease will become extinct in long run.

To verify that the disease extinction is not dependent on the initially available sub-populations in model (2), it is necessary to show that the steady state (DFE) is globally asymptotically stable (GAS).

Lemma 4.2. *The Steady state (DFE) \mathcal{F}_0 of model is globally asymptotically stable if $\mathcal{R}_0 < 1$ and unstable $\mathcal{R}_0 > 1$.*

Proof is given in appendix A

4.3 Endemic Equilibrium

The steady state of the system (2) in presence of the infection i.e. $\lambda \neq 0$ is known as the endemic equilibrium. Let \mathcal{F}_1 represents the arbitrary endemic equilibrium of the model (2).

$$\mathcal{F}_1 = (S^{**}, Q_S^{**}, E^{**}, Q_E^{**}, I^{**}, A^{**}, Q_A^{**}, Q_I^{**}, M^{**}, R^{**}) \quad (5)$$

Further, The force of infection λ can be written in terms of the equilibrium as

$$\lambda^{**} = \frac{\beta}{N^{**}} (I^{**} + \eta_1 Q_I^{**} + \eta_2 A^{**} + \eta_3 Q_A^{**} + \eta_4 M^{**})$$

with $N^{**} = S^{**} + Q_S^{**} + E^{**} + Q_E^{**} + I^{**} + A^{**} + Q_A^{**} + Q_I^{**} + M^{**} + R^{**}$

Solving for the system (2) at this specific fixed point, the endemic equilibrium becomes

$$\begin{aligned} S^{**} &= \frac{\pi(\mu + \xi)}{((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)}; & Q_S^{**} &= \frac{\pi\epsilon}{(\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon}; \\ E^{**} &= \frac{\pi\lambda^{**}\rho(\mu + \xi)}{k_1((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)}; & Q_E^{**} &= \frac{\pi\lambda^{**}\rho\kappa_e(\mu + \xi)}{k_1k_2((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)} \\ I^{**} &= \frac{\pi\lambda^{**}\rho(\mu + \xi)(\nu\kappa_e + k_2\sigma)}{k_1k_2k_3((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)}; & A^{**} &= \frac{\pi\lambda^{**}(1 - \rho)(\mu + \xi)}{k_4((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)}; \\ Q_A^{**} &= \frac{\pi\lambda^{**}(1 - \rho)\kappa_a(\mu + \xi)}{k_4k_5((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)}; & Q_I^{**} &= \frac{\pi\lambda^{**}\rho(\mu + \xi)(\kappa_e(k_3\omega_E + \nu\tau) + k_2\sigma\tau)}{k_1k_2k_3k_6((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)}; \\ M^{**} &= \frac{\pi\lambda^{**}\rho(\mu + \xi)((\nu\kappa_e + k_2\sigma)(k_6\alpha_I + \tau\alpha_Q) + k_3\kappa_e\omega_E\alpha_Q)}{k_1k_2k_3k_6k_7((\lambda^{**} + \mu)(\mu + \xi) + \mu\epsilon)} \\ R^{**} &= \frac{A^{**}\theta_A + \omega Q_A^{**} + \theta Q_I^{**} + \gamma I^{**} + \theta_M M^{**}}{\mu}; \end{aligned} \quad (6)$$

Lemma 4.3. *The model (2) achieves the unique positive endemic equilibrium whenever $\mathcal{R}_0 > 1$.*

Final size of disease COVID-19

In this section, we formulate the final size of the COVID-19 is estimated using the model (2) transmission. Applying the formulation by Arino et.al.[34], define $u \in \mathbb{R}^n$, $u(t) = (E, Q_E, I, A, Q_A, Q_I, M)^T \in \mathbb{R}_+^{10}$ represents the set of infected compartments. Let $v \in \mathbb{R}^m$, $v(t) = (S) \in \mathbb{R}_+$ and $w \in \mathbb{R}^k$, $w(t) = (R, Q_S)^T \in \mathbb{R}_+^2$ represents the susceptible and set of recovered and susceptible quarantine respectively. The model (2) can be restructured as

$$\begin{aligned} u' &= \Pi D\beta(u, v, w)bu - Vu \\ v' &= g(u, v, w) - Dv\beta(u, v, w)bu \\ w' &= h(u, v, w) + Wu \end{aligned} \quad (7)$$

here D is $m \times m$ diagonal matrix with entries that are relative susceptibilities of v compartments. Π is $n \times m$ matrix with spacial property that (i, j) th entry represents the fraction of j th susceptible compartment goes to i th infected compartment. b is a n dimensional row vector with relative horizontal transmission coefficients. $g(u, v, w)$ and $h(u, v, w)$ are functions with uninfected individuals by means of birth, death, quarantine and recovery through natural immunity.

Theorem 4.4. *The final size of the epidemic in model (2) is given by*

$$\ln \left(\frac{S(0)}{S(\infty)} \right) \geq \mathcal{R}_0 \left(\frac{S(0) - S(\infty)}{S(0)} \right) + g_1 E(0) + g_2 Q_E(0) + g_3 I(0) + g_4 A(0) + g_5 Q_A(0) + g_6 Q_I(0) + g_7 M(0). \quad (8)$$

where

$$\begin{aligned} g_1 &= \frac{\beta(\nu\kappa_E + k_2\sigma)(\eta_4 k_6 \alpha_I + \eta_1 k_7 \tau + k_6 k_7 + \eta_4 \tau \alpha_Q)}{k_1 k_2 k_3 k_6 k_7} \\ g_2 &= \beta \left(\frac{\omega_E(\eta_1 k_7 + \eta_4 \alpha_Q)}{k_2 k_6 k_7} + \frac{\nu(\eta_4 k_6 \alpha_I + \eta_1 k_7 \tau + k_6 k_7 + \eta_4 \tau \alpha_Q)}{k_2 k_3 k_6 k_7} \right) \\ g_3 &= \beta \left(\frac{\eta_4(k_6 \alpha_I + \tau \alpha_Q)}{k_3 k_6 k_7} + \frac{\eta_1 \tau + k_6}{k_3 k_6} \right), \quad g_4 = \beta \left(\frac{\eta_3 \kappa_A}{k_4 k_5} + \frac{\eta_2}{k_4} \right) \\ g_5 &= \frac{\beta \eta_3}{k_5}, \quad g_6 = \beta \left(\frac{\eta_1}{k_6} + \frac{\eta_4 \alpha_Q}{k_6 k_7} \right), \quad g_7 = \frac{\beta \eta_4}{k_7} \end{aligned}$$

4.3.1 Uniform Persistence

Let $\mathcal{I} = (E, Q_E, I, A, Q_A, Q_I, M)$. Then $(\mathcal{I})'(t) = A(x(t))\mathcal{I}(t)$, where

$$A(x) = \begin{pmatrix} -k_1 & 0 & \frac{\beta\rho}{N} & \frac{\beta\rho\eta_2}{N} & \frac{\beta\rho\eta_3}{N} & \frac{\beta\rho\eta_1}{N} & \frac{\beta\rho\eta_4}{N} \\ \kappa_E & -k_2 & 0 & 0 & 0 & 0 & 0 \\ \sigma & \nu & -k_3 & 0 & 0 & 0 & 0 \\ 0 & 0 & \frac{\beta(1-\rho)}{N} & \frac{\beta\eta_2(1-\rho)}{N} - k_4 & \frac{\beta\eta_3(1-\rho)}{N} & \frac{\beta\eta_1(1-\rho)}{N} & \frac{\beta\eta_4(1-\rho)}{N} \\ 0 & 0 & 0 & \kappa_A & -k_5 & 0 & 0 \\ 0 & \omega_E & \tau & 0 & 0 & -k_6 & 0 \\ 0 & 0 & \alpha_I & 0 & 0 & \alpha_Q & -k_7 \end{pmatrix}, \text{ and} \quad (9)$$

Denote by $s(A)$ the spectral bound of matrix A . Let $\rho : \mathbb{R}_+^{10} \rightarrow \mathbb{R}_+$,

$$\rho(x) = \min_{i=1}^7 \mathcal{I}_i. \quad (10)$$

Theorem 4.5. *If $R_0 > 1$ then the disease is strongly uniformly ρ -persistent: $\exists \varepsilon > 0$ such that*

$$\liminf_{t \rightarrow \infty} \rho(x(t)) > \varepsilon, \quad (11)$$

whenever $\rho(x(0)) > 0$. Where $x(t) = (S(t), Q_S(t), E(t), Q_E(t), I(t), A(t), Q_A(t), Q_I(t), M(t), R(t))$ be a solution of model (2).

The above persistence result shows that the disease will persist and there will be an endemic steady state if the value of the basic reproductive number is greater than 1.

5 Numerical Simulations

Matlab(ODE 45) is used to perform the simulations with the parameter values given in the Tab.4. The time series solutions are shown in Fig. 2, it is apparent that model (2) achieves the Endemic equilibrium respectively whenever the threshold quantity \mathcal{R}_0 is more than the unity and the DFE whenever \mathcal{R}_0 is less than the unity authenticating the qualitative results.

We now investigate the effects of medication on the quarantined population, taking into account both the rate and efficacy of medication in Fig.3(a) and (c). We also look into the effect of the medication rate and efficacy on the number of days spent in quarantine in Fig.3(e) and (g).

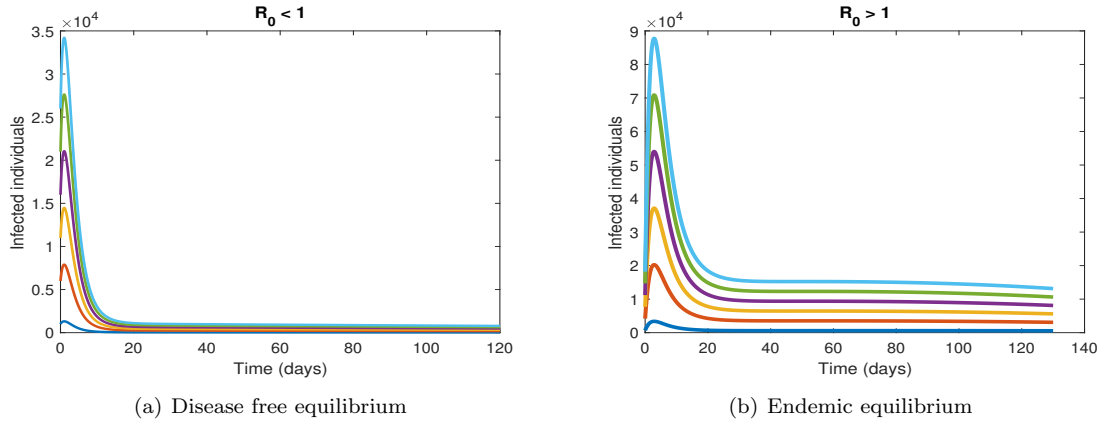

Figure 2: Time Series Analysis

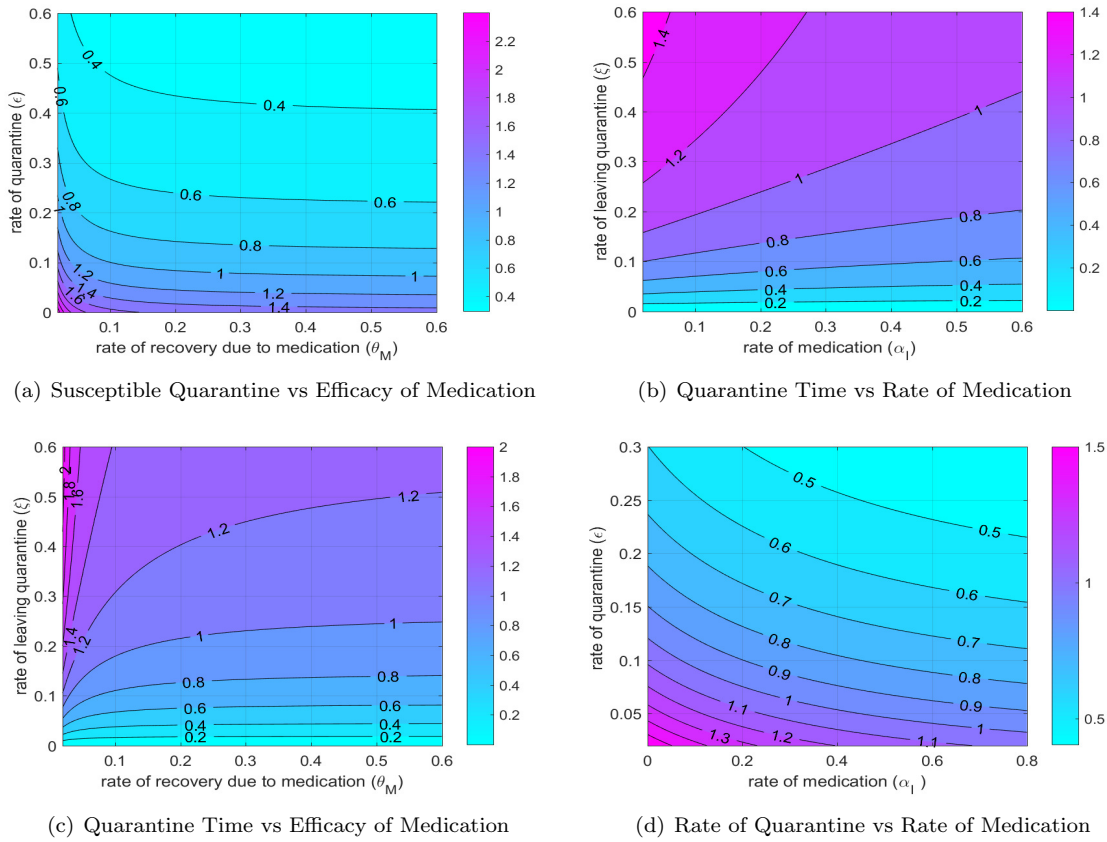

Figure 3: Contour's of R_0

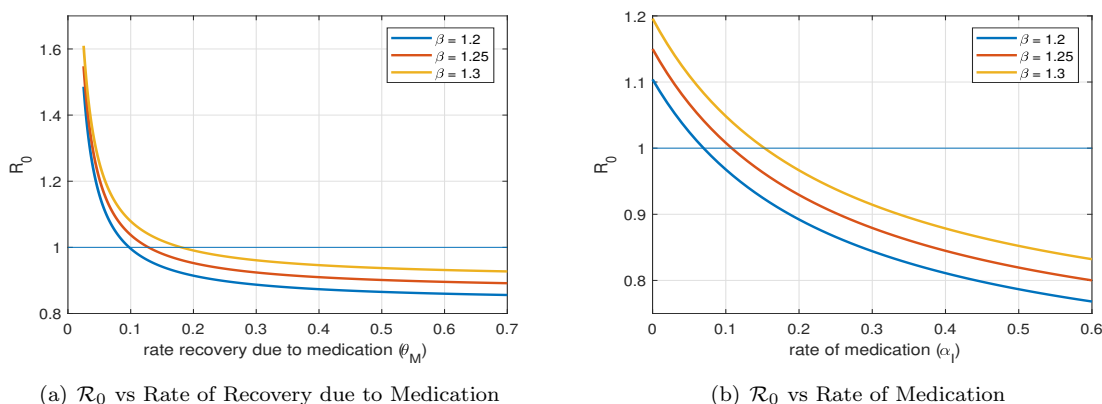

Figure 4: Dependence of \mathcal{R}_0 on Medication

We observe that for a realistic recovery rate due to medication (based on the studies thus far), we would have to maintain a quarantine rate of (20 %) or higher in order to have over threshold quantity $\mathcal{R}_0 < 1$, however for high quarantine rates a less effective medication will suffice. This illustrates that fact that in order to ease the lock down we need effective medication. Moreover, over a range of different realistic contact rates β , we need certain level of effectiveness of the medication as is shown in Fig.3(b).

These observations point towards the fact that even with the availability of medication, while the social distancing measures may be relaxed but they probably cannot be completely done away with until a vaccine is found.

6 Sensitivity Analysis

The source of sensitivity is due the variation found in the parameters. This section deals with the sensitive parameters to \mathcal{R}_0 i.e. how much \mathcal{R}_0 changes upon small perturbations of the parameters. This will give us insights about the parameters that we can use in devising our control strategies. PRCC (Partial Rank Correlation Coefficient) method is effective tool which compute the impact of parameters on \mathcal{R}_0 . The positive(negative) PRCC indicates the positive(negative) correlation parameters with the output variable. The parameters involved in \mathcal{R}_0 are studied which are $\mu, \nu, \beta, \sigma, \tau, \kappa_E, \omega_E, \gamma, \theta_A, \kappa_A, \rho, \epsilon, \xi, \theta, \theta_M, \alpha_I, \alpha_Q$. Fig. 5 indicates that the most sensitive parameter of model (2) are β, ϵ, τ and α_I thus pointing towards the control strategies such as quarantine, isolation and medication.

Figure 5: Sensitivity of the Parameters

7 Estimation of Basic Reproduction Number \mathcal{R}_0

The threshold quantity \mathcal{R}_0 , basic reproduction number is the expected number of the newly infected individuals caused by the single infected individual. It is convenient to estimate the \mathcal{R}_0 from the data in order to have better insights about COVID-19. The Estimates of \mathcal{R}_0 depend upon the estimation of critical parameters such as contact rate β , incubation rate σ , the recovery γ , and other involving parameters. The estimation is performed by fitting COVID-19 data of Italy, Spain, India, and Pakistan via nonlinear least square method. The underlying fitting model is based upon an extension of SEIR by incorporating the effect of Quarantine, Isolation, and Asymptomatic (the reduced model of Imran et al [24]).

$$\begin{aligned}
 \frac{dS}{dt} &= \Pi + \xi Q_S - (\lambda + \mu + \epsilon)S \\
 \frac{dQ_S}{dt} &= \epsilon S - (\xi + \mu)Q_S \\
 \frac{dE}{dt} &= \rho \lambda S - (\sigma + \mu)E \\
 \frac{dI}{dt} &= \sigma E - (\delta_I + \tau + \mu + \gamma)I \\
 \frac{dA}{dt} &= (1 - \rho)\lambda S - (\kappa_A + \mu)A \\
 \frac{dQ_I}{dt} &= \tau I - (\theta + \delta_Q + \mu)Q_I \\
 \frac{dR}{dt} &= \gamma I + \theta_A A + \theta Q_I - \mu R
 \end{aligned} \tag{12}$$

where λ is the force of infection

$$\lambda = \frac{\beta}{N} (I + \eta_1 Q_I + \eta_2 A) \tag{13}$$

Here Π is the recruitment rate, which depends upon the demographic area from the data is taken. $\frac{1}{\mu}$ is the average life span of human life. The effective contact rate is the most crucial parameter, which describes the average associated chance of getting infected by the interaction of the susceptible individuals with the infected ones. The direct measure of beta is tricky unless an epidemic is completed. However, an indirect approach indicated by Chávez et al. [42] can be adopted to estimate the β for \mathcal{R}_0 .

$$\mathcal{R}_0 = \frac{\beta(\mu + \xi)}{\mu + \xi + \epsilon} \left\{ (1 - \rho) \left(\frac{\eta_2}{k_4} \right) + \rho \left[\left(\frac{\sigma}{k_1 k_3} \right) \left(\frac{\eta_1 \tau}{k_6} + 1 \right) \right] \right\} \quad (14)$$

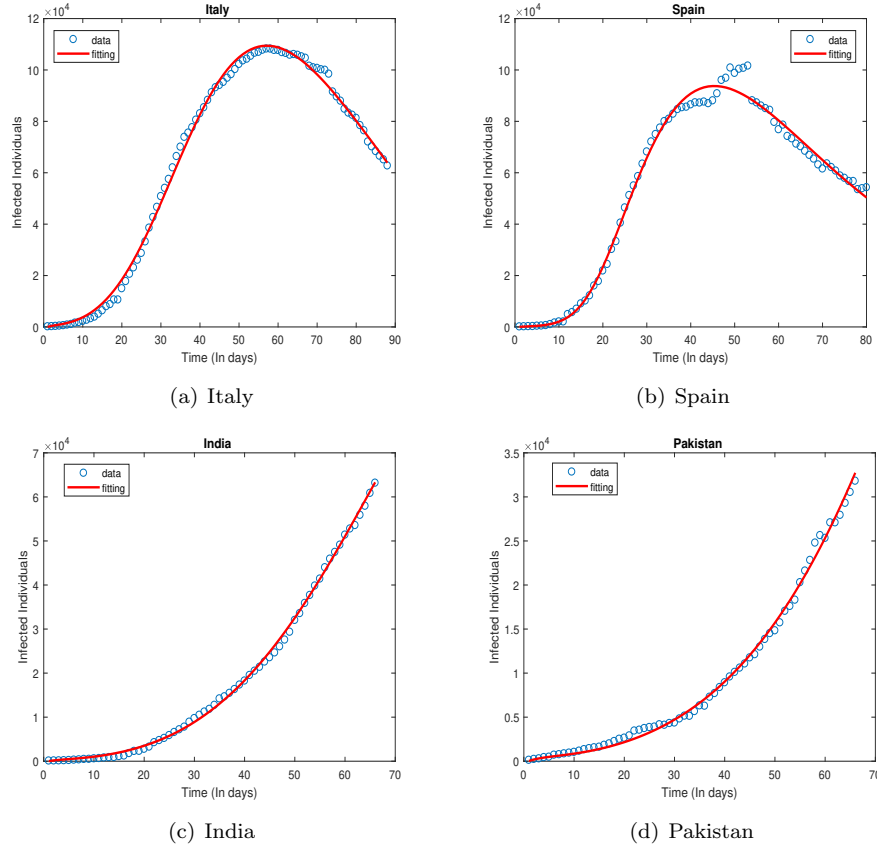

Figure 6: Parameter Estimation

The ordinary least squares (OLS) scheme is used to estimate the Tab 7 paramters. Since the observed data values is assumed to have constant variance error distribution. So, we can write the estimation scheme as

$$Y_i = f(t_i, \Theta_{OLS}) + \epsilon_i \quad (15)$$

where Y_i and Θ_{OLS} are data observes and set of parameters involving fitting process respectively.

The optimized set of parameters can be obtained by minimizing the least squared sum over the set of estimated parameters.

The Matlab tool is used to perform this optimization under the trust-region-reflective algorithm to find the best fit of the selected parameters. The bootstrap method suggested by the Efron and Tibshirani [43] to use the

associated 95 % confidence intervals.

$$\hat{\Theta}_{OLS} = \arg \min_{\Theta \in \Omega} \sum_{i=1}^n [Y_i - f(t_i, \Theta)]^2 \quad (16)$$

Table 1: Parameter Estimates for Different Countries

Parameters	Italy	Spain	India	Pakistan
β	1.4 (1.3-1.4)	2.2 (2.1-2.4)	0.87 (0.85-0.91)	0.68 (0.66-0.71)
σ	0.33 (0.31-0.35)	0.11 (0.11-0.12)	0.19 (0.19-0.2)	0.15 (0.15-0.16)
γ	0.099 (0.094-0.1)	0.15 (0.14-0.17)	0.12 (0.11-0.14)	0.11 (0.10-0.12)
ϵ	0.11 (0.10,0.12)	0.054 (0.05-0.066)	0.079 (0.074-0.082)	0.065 (0.062-0.068)
ρ	0.8 (0.79-0.81)	0.74 (0.73-0.75)	0.72 (0.71 – 0.73)	0.66 (0.65-0.68)
\mathcal{R}_0	1.1408	2.6327	1.3144	1.2303

Table 2: Estimates of \mathcal{R}_0 for Different Epidemic Phases

\mathcal{R}_0	Italy	Spain	India	Pakistan
Initial Phase	2.15	2.59	1.3144	1.2303
Up to Middle Phase	2.99	3.7	-	-
Up to Now	1.1408	2.6327	1.3144	1.2303

We note that the values of $\mathcal{R}_0 = 1.31$ and 1.23 respectively for India and Pakistan are relatively small considering that the outbreak there is still in the growth phase. There has been a lot of speculation regarding why the outbreak in these countries has been less severe, but nothing conclusive can be said. The low value of the contact rate could mean either an effective quarantine or the probability of infection being lower. We also note that the proportion of asymptomatic individuals is 72% and 66% respectively in India and Pakistan, this is consistent with other estimates for a wider population as well.

For Italy where the epidemic curve is falling due to the strict lock down, we note that the value of R_0 comes out to be 1.14, similarly for Spain R_0 comes out to be 2.6, the values seems to be on the higher side and can be attributed to a sharp increase in the number of cases around week 7. The asymptomatic population is estimated to be 80% and 74% for Italy and Spain, again within the range of estimates in the literature.

8 Control Strategies for the Outbreak

The theory of optimal control developed by Lev Pontryagin and his collaborators is used for models where the underlying dynamics are governed by systems of differential equations. The 'Pontryagin's maximum principle' algorithm allows us to minimize a 'cost functional' subject to differential equation constraints. It has found wide application in biological models including epidemic models [25, 26, 29]. The goal here is to reduce the infected population by means of specific controls, which may appear as time dependent parameters in the model, while minimizing the required resources. The algorithm is implemented by appending an adjoint system of differential equations having a terminal conditions along with the original state system. Further details regarding Optimal Control and adjoint system can be found in [36], [37]. In our study numerical results are produced using the forward (state system) backward (adjoint system) sweep method with a fourth-order backward Runge-Kutta method.

In this paper, we devise optimal control strategies for quarantine of susceptibles and the isolation and medication of infected individuals that will reduce the infection while keeping the cost at a minimum. The cost includes the costs associated with the disease burden, as well as the cost of implementing the control strategy.

8.1 Optimal Medication with Isolation and Quarantine

In the recent COVID-19 pandemic, the most effective and widely used method to reduce the infection has been the quarantine of the susceptible population, along with isolation of the confirmed infected individuals. We now have the possibility of having medication available to help control the outbreak as mentioned in section 1 Introduction. In this section, we determine time dependent strategies for the medication rate α_I , isolation rate τ and the rate of quarantine ϵ to effectively control the infected population and at the same time keeping the associated cost low. Let U be the control set defined for the three parameters α_I, τ, ϵ

$$U = \{\alpha_I(t), \tau(t), \epsilon(t) : 0 \leq \alpha_I(t), \tau(t), \epsilon(t) \leq \zeta_i, 0 \leq t \leq T, 0 < \zeta_i \leq 1, i = 1, 2, 3\}$$

here $\alpha_I(t), \tau(t), \epsilon(t)$ are Lebesgue measurable and $\zeta_i, \forall i = 1, 2, 3$ are positive numbers which are maximum values for the respective parameters. Our main objective to minimize the functional involving the infected sub populations along with the described control parameters.

$$J[\alpha_I, \tau(t), \epsilon(t)] = \int_0^T \left(I(t) + A(t) + \frac{1}{2}W_1\alpha_I^2(t) + \frac{1}{2}W_2\tau^2(t) + \frac{1}{2}W_3\epsilon^2(t) \right) dt \quad (17)$$

where W_i for $i = 1, 2, 3$ are cost balancing coefficients assigned to the medication, isolation and susceptible quarantine parameters, these are needed as the parameters themselves have values between 0 and 1, while the infected population is in the thousands, further they can be used to assign relative importance to the different control parameters. Our focus is to find the optimal values for the control parameters $\alpha_I^*(t), \tau^*(t), \epsilon^*(t)$ such that

$$J[\alpha_I^*(t), \tau^*(t), \epsilon^*(t)] = \min_{(\alpha_I, \tau, \epsilon) \in U} J[\alpha_I(t), \tau(t), \epsilon(t)]$$

We are interested in studying the effects that medication may have on quarantine and isolation strategies. With the rising socio economic cost of a strict quarantine and the burden on health facilities to isolate infected individuals effective medication may alleviate some of the factors. We would also like to look into the costs associated with using medication along with quarantine and isolation to control the epidemic.

Our main result for this section is given below. For the details of formulation of the Hamiltonian and the adjoint system along with finding the optimality conditions the reader is referred to the Appendix.

Theorem 8.1. *There exist unique optimal controls $\alpha_I^*(t), \tau^*(t), \epsilon^*(t)$, represented in (25), which minimize the functional J over the control set U . Also, there exists an adjoint system of ϕ_i 's such that the optimal medication, isolation and quarantine (susceptible) are characterized as (24). Moreover, The adjoint system (24) satisfies the transversality conditions $\{\phi_i(T) = 0, i = 1, 2, \dots, 10\}$.*

8.2 Control Strategies and Comparison

We determine the optimal quarantine ($\epsilon(t)$ and isolation $\tau(t)$) strategies when medication is available, we also consider the case when no medication is available. We would like to compare the quarantine and isolation strategies in both scenarios, this will help us understand the role medication may play in easing strict lock downs and isolation. We also determine the optimal medication strategy α_I and the costs associated with implementing these strategies.

Figure 7: Optimal control comparison

The Fig. 7(a) shows that there is a reduction in cost when medication is used in addition to quarantine and isolation, this may appear counter intuitive at first, but we note that the cost includes the cost of disease burden in addition to the cost associated with applying the control strategy itself.

This idea is made clearer by Fig7(b) in which the total optimal infected population over time is given under two and three controls. We see that the addition of medication as a control mechanism reduces the infected population, thereby reducing the cost which includes the disease burden. In Fig.7(c,d), isolation and quarantine strategies are shown in the presence and absence of medication. These graphs clearly indicate that using medication significantly reduces the quarantine and isolation rates needed to control the outbreak. This decrease is observed in both the time of maximum quarantine and isolation and the faster decrease in the rates over time.

We now consider the quarantine strategies for a variety of realistic contact rates β and for different medication efficacies θ_M . The efficacy of medication is defined in terms of reducing the time it takes to recover from the disease once medication is started. As noted in the Introduction, several promising treatments are being evaluated, all of these in initial trials have reduced the symptoms and infectiousness. We note that for a higher contact rates and we require a more strict quarantine to be in place, this is reflected in the fact that the maximum rate of

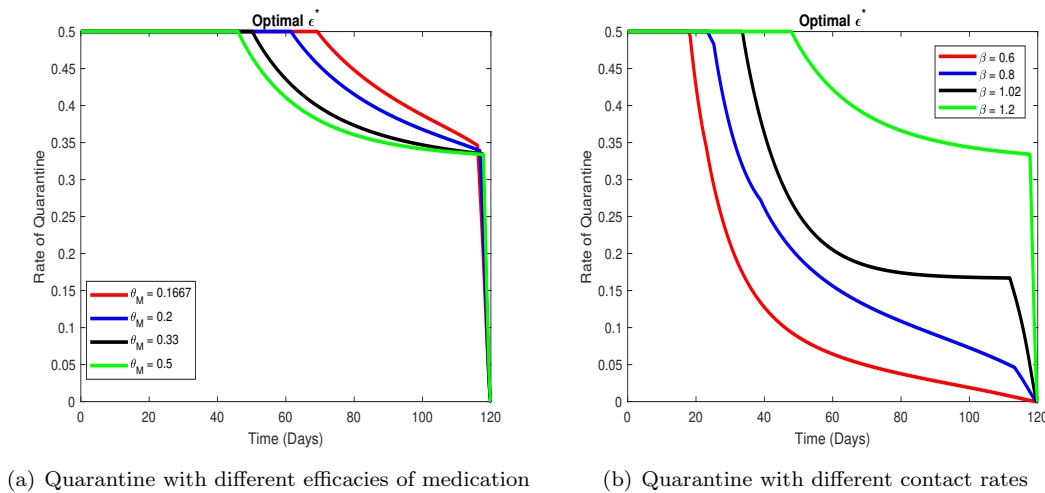

Figure 8: Optimal control comparison

quarantine has to be maintained for a longer time and the drop in the quarantine rate is slower for higher contact rates. We also see that for lower medication efficacy, reflected in the average time for recovery after medication $\frac{1}{\theta}$, a stricter quarantine must be put in place and eased at a slower rate over a longer period of time. Our main finding is that the availability of medication will help in easing the strict quarantine in place, moreover the cost of implementing the control strategies (which includes the cost of disease burden) is also reduced with the availability and use of medication.

9 Conclusion

The study considered a compartmental model for the transmission dynamics and control of COVID-19. We included quarantine, isolation as well as medication as possible control mechanisms for the disease. We look into how the availability of medication may affect the control strategies in place, specially the strict quarantine measures. We also studied how these measures depend on the rate and efficacy of the medication.

This model was an extension of an earlier model [24] incorporating a 'treatment' compartment. We established the existence of a threshold quantity R_0 and showed that the disease dies out whenever $R_0 < 1$ and is endemic in the population if $R_0 > 1$, which basically means that in order to control the disease measures should be taken to reduce R_0 to be less than 1. We also calculate the final size of the epidemic. We look at how R_0 depends on the quarantine rate and the rate and efficacy of the medication. Our results show that using realistic values for the rate and efficacy of the treatment we still need to quarantine the susceptible population albeit at a smaller rate. We further study how the rate and efficacy affect the average time needed to stay in quarantine, our results show that with the availability of effective medication the average time in quarantine is significantly reduced. This leads us to conclude that once medication is available to a wider population the lock down measures can be eased. We estimated R_0 for four different countries. India and Pakistan, where the curve is still rising, have shown very different COVID-19 transmission dynamics. The initial growth rates have been much slower with a much lower mortality rate as compared to China, Europe and North America. At this stage of the epidemic, R_0 has been estimated to be 1.35 and 1.2 respectively. In Spain and Italy where the epidemic curve is now falling, after a strict lock down was imposed, R_0 has been estimated to be 1.28 and 1.12 respectively. We further provided an estimate of the proportion of asymptomatic individuals in the population, this comes out to be around 25% which is in agreement with other studies.

We next looked at effective control measures. Using sensitivity analysis we concluded that R_0 was most sensitive to the contact rate β , the rates of entering and leaving quarantine, ϵ and ξ respectively and the rate of medication

of the infected population α_I . Using this information we used optimal control theory to devise optimal quarantine, isolation and medication strategies. We also compared the strategies in the availability and non availability of medication. We observe that that quarantine is less severe when treatment is available. Moreover, we looked at the required quarantine rate for effectively controlling the disease, in the presence of medication for different realistic values of the contact rate and efficacy of the medication.

This study was motivated by the positive news regarding initial clinical trials of some plausible treatments for COVID-19. Thus far the only effective control measures were non pharmaceutical interventions including social distancing measures, quarantine and isolation, all of which have had a socio-economic cost. Many countries have started to relax these measures despite serious reservations expressed by the health authorities due to economic and political reasons. We have shown that with the availability of effective medication it may be possible to relax some of the measures while keeping the outbreak under control. However, our study also shows that along with treatment some level of social distancing will have to be maintained, at least until a vaccine is found. Quarantine and Isolation measures have resulted in bring down the value of R_0 in Spain and Italy significantly, while in India and Pakistan where the outbreak is still in the growth phase, R_0 values at the moment are low, however any premature relaxation in the lock down, specially till medication is widely available may result in much more severe outbreak.

A Appendix

A.1 Proof of Lemma 3.1

Proof. Adding the equations of model (2), this results in change in total population as

$$\begin{aligned}\frac{dN}{dt} &= \Pi - \mu N - (\delta_I + \delta_Q) \leq \Pi - \mu N \\ \frac{dN}{dt} &\leq \Pi - \mu N\end{aligned}\quad (18)$$

It follows that

$$N(t) \leq N(0)e^{-\mu t} + \frac{\Pi}{\mu} (1 - e^{-\mu t}) \quad (19)$$

Thus model (2) solutions exists for given initial conditions, and are eventually bounded on every finite time interval. \square

A.2 Proof of Lemma 3.2

Proof. Using (18) and (19), it follows that as time approaches to infinity $t \rightarrow \infty$, the population is bounded by the positive number so the set \mathcal{D}

$$N(t) \leq \frac{\Pi}{\mu}$$

therefore, the set \mathcal{D} is positively invariant. \square

A.3 Proof of Lemma 4.2

Proof. Consider the Lyapunov function for model (2).

$$\mathcal{L} = h_1 E + h_2 Q_E + h_3 I + h_4 A + h_5 Q_A + h_6 Q_I + h_7 M \quad (20)$$

where

$$\begin{aligned}h_1 &= \frac{(\nu\kappa_E + k_2\sigma)(\eta_4 k_6 \alpha_I + \eta_1 k_7 \tau + k_6 k_7 + \eta_4 \tau \alpha_Q)}{k_1 k_2 k_3 k_6 k_7} + \frac{\kappa_E \omega_E (\eta_1 k_7 + \eta_4 \alpha_Q)}{k_1 k_2 k_6 k_7} \\ h_2 &= \frac{\omega_E (\eta_1 k_7 + \eta_4 \alpha_Q)}{k_2 k_6 k_7} + \frac{\nu (\eta_4 k_6 \alpha_I + \eta_1 k_7 \tau + k_6 k_7 + \eta_4 \tau \alpha_Q)}{k_2 k_3 k_6 k_7} \\ h_3 &= \frac{\eta_4 (k_6 \alpha_I + \tau \alpha_Q)}{k_3 k_6 k_7} + \frac{\eta_1 \tau + k_6}{k_3 k_6}, \quad h_4 = \frac{\eta_3 \kappa_a}{k_4 k_5} + \frac{\eta_2}{k_4}, \\ h_4 &= \frac{\eta_3}{k_5}, \quad h_5 = \frac{\eta_3}{k_5}, \quad h_6 = \frac{\eta_1}{k_6} + \frac{\eta_4 \alpha_Q}{k_6 k_7}, \quad h_7 = \frac{\eta_4}{k_7}\end{aligned}$$

The Lyapunov derivative $\dot{\mathcal{L}}$ is given as

$$\begin{aligned}\dot{\mathcal{L}} &= h_1 \dot{E} + h_2 \dot{Q}_E + h_3 \dot{I} + h_4 \dot{A} + h_5 \dot{Q}_A + h_6 \dot{Q}_I + h_7 \dot{M} \\ &= h_1 (\rho \lambda S - k_1 E) + h_2 (\kappa_E E - k_2 Q_E) + h_3 (\sigma E + \nu Q_E - k_3 I) \\ &\quad + h_4 ((1 - \rho) \lambda S - k_4 A) + h_5 (\kappa_A A - k_5 Q_A) + h_6 (\tau I + \omega_E Q_E - k_6 Q_I) \\ &\quad + h_7 (\alpha_I I + \alpha_Q Q_I - k_7 M) \\ \dot{\mathcal{L}} &= S (h_1 \lambda \rho - h_4 \lambda (\rho - 1)) + h_5 (A \kappa_a - k_5 Q_a) - g_4 k_4 A + h_3 (\nu Q_E + \sigma E - k_3 I) \\ &\quad + h_2 (\kappa_E E - k_2 Q_E) + h_6 (\omega_E Q_E - k_6 Q_I + \tau I) - h_1 k_1 E + h_7 (I \alpha_I + Q_I \alpha_Q - k_7 (M))\end{aligned}$$

Since $S(t) \leq N \in \mathcal{D}$, Thus

$$\dot{\mathcal{L}} \leq (I + \eta_1 Q_I + A\eta_2 + \eta_3 Q_a + \eta_4 M) (\mathcal{R}_0 - 1) \quad (21)$$

Thus, if $\dot{\mathcal{L}} \leq 0$ if $\mathcal{R}_0 \leq 1$ with $\dot{\mathcal{L}} = 0$ iff $E = 0, Q_E = 0, I = 0, A = 0, Q_A = 0, Q_I = 0$ and $M = 0$. Additionally, the super compact set $\{(S, Q_S, E, Q_E, I, A, Q_A, Q_I, M, R) \in \mathcal{D} : \dot{\mathcal{L}} = 0\}$ is the singleton \mathcal{F}_0 . Thus, LaSalle Invariance Principle Theorem 6.4 [33] guaranties that every solution to the model (2) initial conditions from \mathcal{D} converge to DFE \mathcal{F}_0 as $t \rightarrow \infty$. Hence, $(E, Q_E, I, A, Q_A, Q_I, M) \rightarrow (0, 0, 0, 0, 0, 0, 0)$ as $t \rightarrow \infty$, It follows that $\{(S, Q_S, E, Q_E, I, A, Q_A, Q_I, M, R)\} \rightarrow (S^*, Q_S^*)$ as $t \rightarrow \infty$ for \mathcal{R}_0 . Hence, \mathcal{F}_0 is GAS $\in \mathcal{D}$ for \mathcal{R}_0 . \square

A.4 Proof of theorem 4.4

Proof. Since $m = 1, n = 7$ and $k = 2$, the above matrices can be written as

$$D = [1], \quad \Pi = \begin{bmatrix} \rho \\ 0 \\ 0 \\ 1 - \rho \\ 0 \\ 0 \\ 0 \end{bmatrix}, \quad b = \begin{bmatrix} 0 \\ 0 \\ 1 \\ \eta_2 \\ \eta_3 \\ \eta_1 \\ \eta_4 \end{bmatrix}^T, \quad W = \begin{bmatrix} 0 & 0 \\ 0 & 0 \\ \gamma & 0 \\ \theta_A & 0 \\ \omega_A & 0 \\ \theta & 0 \\ \theta_M & 0 \end{bmatrix}^T \quad (22)$$

$$g(u, v, w) = (\pi + \xi Q_s - (\mu + \epsilon)S), \quad h(u, v, w) = \begin{bmatrix} -\mu R \\ \epsilon S - (\xi + \mu)Q_S \end{bmatrix}$$

Consider the formulation of the m-dimensional row vector

$$\Gamma = [\Gamma_1, \Gamma_2, \dots, \Gamma_m] = \beta b V^{-1} \Pi D \quad (23)$$

It follows from the theorem 2.1 from Arino et.al[34], $\mathcal{R}_0 = \Gamma y(0)$. Also, the final size can be computed as

$$\begin{aligned} \ln \left(\frac{S(0)}{S(\infty)} \right) &= \beta b V^{-1} \Pi D (v(0) - v(\infty)) + \beta b V^{-1} u(0) \\ \implies \ln \left(\frac{S(0)}{S(\infty)} \right) &= \Gamma D^{-1} (v(0) - v(\infty)) + \beta b V^{-1} u(0) \\ \implies \ln \left(\frac{S(0)}{S(\infty)} \right) &= \frac{\mathcal{R}_0}{v(0)} (v(0) - v(\infty)) + \beta b V^{-1} u(0) \end{aligned}$$

Thus, with the given initial conditions $u(0), v(0)$, the final size of epidemic is represented by (8). \square

A.5 Proof of Theorem 4.5

Proof. Let $X = \{x \in \mathbb{R}_+^{10} \mid E = Q_E = I = A = Q_A = Q_I = M = 0\}$ (that is, X is the disease-free subspace). Let $M = \mathcal{D} \cap X$. Note that both X , as well as M , are positively invariant. $\mathcal{F}_i \in M$ and it attracts all the trajectories in X . \mathcal{F}_i is asymptotically stable in X . Hence \mathcal{F}_i is isolated in X . Corollary 4.7 in [39] (where $M = B \cap X$, $\Omega(M) = \{\mathcal{F}_i\}$, $T = 1$, $P(1, E_0)$ is $e^{A(E_0)}$), together with Proposition 4.1 and Lemma 3.1 in [39], imply that $\{\mathcal{F}_i\}$ is uniformly weakly repelling. Then, from Theorem 8.17 in [40] we have that the semi-flow generated by (2.4) is uniformly weakly ρ -persistent. From the positive invariant of \mathcal{D} , we have that (2.4) is point dissipative. Then, according to Theorem 2.28 in [40], there exists a compact attractor of points for the model (2). This, together with uniformly weakly ρ -persistent imply (11). \square

A.6 Proof of Theorem 8.1

Proof. The Hamiltonian can be written as

$$\begin{aligned}
 H = & \frac{1}{2}W_1\alpha_I^2 + \frac{1}{2}W_2\tau^2 + \frac{1}{2}W_3\epsilon^2 + I + A + \phi_1 \left(\Pi + \xi Q_S - (\lambda + \mu + \epsilon) S \right) \\
 & + \phi_2 \left(\epsilon S - (\mu + \xi) Q_S \right) + \phi_3 \left(\rho \lambda S - (\kappa_e + \mu + \sigma) E \right) \\
 & + \phi_4 \left(\kappa_E E - (\omega_E + \mu + \nu) Q_E \right) + \phi_5 \left(\nu Q_E + \sigma E - (\gamma + \delta_I + \mu + \tau + \alpha_I) I \right) \\
 & + \phi_6 \left((1 - \rho) \lambda S - (\theta_A + \kappa_A + \mu) A \right) + \phi_7 \left(\kappa_A A - (\omega_A + \mu) Q_A \right) \\
 & + \phi_8 \left(\omega_E Q_E + \tau I - (\delta_A + \theta + \alpha_Q + \mu) Q_I \right) + \phi_9 \left(\alpha_I I + \alpha_Q Q_I - (\theta_M + \mu) M \right) \\
 & + \phi_{10} \left(\theta_A A + \omega_A Q_A + \theta Q_I + \gamma I + \theta_M M - \mu R \right)
 \end{aligned}$$

One can find that the Integrand $J(\cdot)$ is convex with respect to the control variables α_I , τ and ϵ . By lemma (3.1), the state model (2) solutions are bound above $N(t) \leq \frac{\Pi}{\mu}$, $\forall t > 0$. Moreover, The model follows Lipschitz property to the state variables. The convexity of the integrand J , boundedness of solutions of the state model and Lipschitz property guarantee us the optimal values of the control variables over the set U solutions [35]. Hence, establishing the existence of the control variables. The adjoint system is a acquired by means of Pontryain's Maximum principle conditions

$$\begin{aligned}
 \frac{d\phi_1}{dt} &= -\frac{\partial H^*}{\partial S}, \phi_1(T) = 0 \\
 \frac{d\phi_2}{dt} &= -\frac{\partial H^*}{\partial Q_S}, \phi_2(T) = 0 \\
 &\vdots \quad \quad \quad \vdots \\
 \frac{d\phi_{10}}{dt} &= -\frac{\partial H^*}{\partial R}, \phi_{10}(T) = 0
 \end{aligned}$$

The adjoint system is given as

$$\begin{aligned}
 \frac{d\phi_1}{dt} &= (\mu + \epsilon + \lambda)\phi_1 - \epsilon\phi_2 - \rho\lambda\phi_3 - (1 - \rho)\lambda\phi_6 \\
 \frac{d\phi_2}{dt} &= (\mu + \xi)\phi_2 - \xi\phi_1 \\
 \frac{d\phi_3}{dt} &= (\mu + \sigma + \kappa_E)\phi_3 - \kappa_E\phi_4 - \sigma\phi_5 \\
 \frac{d\phi_4}{dt} &= (\mu + \nu + \omega_E)\phi_4 - \nu\phi_5 - \omega_E\phi_8 \\
 \frac{d\phi_5}{dt} &= -1 + \frac{\beta S\phi_1}{N} - \frac{\beta\rho S\phi_3}{N} + (\mu + \gamma + \tau + \delta_I + \alpha_I)\phi_5 - \frac{\beta(1 - \rho)S\phi_6}{N} - \tau\phi_8 - \gamma\phi_{10} - \phi_9\alpha_I \quad (24) \\
 \frac{d\phi_6}{dt} &= -1 + \frac{\eta_1\beta S\phi_1}{N} - \frac{\eta_1\beta\rho S\phi_3}{N} + (\mu + \theta_A + \kappa_A)\phi_6 - \frac{\eta_1\beta(1 - \rho)S\phi_6}{N} - \kappa_A\phi_7 - \theta_A\phi_{10} \\
 \frac{d\phi_7}{dt} &= \frac{\eta_2\beta S\phi_1}{N} - \frac{\eta_2\beta\rho S\phi_3}{N} - \frac{\eta_2\beta(1 - \rho)S\phi_6}{N} + (\mu + \omega_A)\phi_7 - \omega_A\phi_{10} \\
 \frac{d\phi_8}{dt} &= \frac{\eta_3\beta S\phi_1}{N} - \frac{\eta_3\beta\rho S\phi_3}{N} - \frac{\eta_3\beta(1 - \rho)S\phi_6}{N} + (\mu + \theta + \delta_Q + \alpha_Q)\phi_8 - \theta\phi_{10} \\
 \frac{d\phi_9}{dt} &= \frac{\beta\eta_4 S\phi_1}{N} - \frac{\beta\eta_4\rho S\phi_3}{N} - \frac{\beta\eta_4(1 - \rho)S\phi_6}{N} + (\mu + \theta_m)\phi_9 - \theta_m\phi_{10} \\
 \frac{d\phi_{10}}{dt} &= \mu\phi_{10}
 \end{aligned}$$

The optimality condition gives:

$$\begin{aligned}\frac{\partial H^*}{\partial \alpha_I} = 0 &\implies \alpha_I = \left(\frac{I(\phi_5 - \phi_9)}{W_1} \right) \\ \frac{\partial H^*}{\partial \tau} = 0 &\implies \tau = \left(\frac{I(\phi_5 - \phi_8)}{W_2} \right) \\ \frac{\partial H^*}{\partial \epsilon} = 0 &\implies \epsilon = \left(\frac{S(\phi_1 - \phi_2)}{W_3} \right)\end{aligned}$$

Since the control are bounded in set in U , setting the max limits to the controls α_I, τ and ϵ by ζ_1, ζ_2 and ζ_3 respectively. The optimal controls becomes:

$$\begin{aligned}\alpha_I^*(t) &= \min \left[\zeta_1, \max \left(0, \frac{I(\phi_5 - \phi_9)}{W_1} \right) \right] \\ \tau^*(t) &= \min \left[\tau_{\max}, \max \left(0, \frac{I(\phi_5 - \phi_8)}{W_2} \right) \right] \\ \epsilon^*(t) &= \min \left[\epsilon_{\max}, \max \left(0, \frac{S(\phi_1 - \phi_2)}{W_3} \right) \right]\end{aligned}\tag{25}$$

□

The uniqueness of optimal controls followed from the uniqueness of the optimal uniqueness of the optimality systems (state and adjoint).

B Tables

Variable	Description
N	Total population
S	Susceptible individuals
E	Individuals Exposed to corona virus
Q_S	Individuals susceptible Quarantined
I	Individuals Infected with corona virus
A	Asymptomatic Individuals
Q_E	Quarantine of Exposed individuals
Q_I	Isolated individuals
Q_A	Quarantine of Asymptomatic individuals
M	Medication of individuals
R	Recovered from corona virus

Table 3: Description of the variables of the model

Parameters	Description	Values	
Π	Recruitment rate of humans	100	Assumed
μ	Natural death rate of humans	60 years	Assumed
δ_I	Disease-induced death rate individuals	0.065 day^{-1}	Estimated
δ_Q	Disease-induced death rate of isolated individuals	0.04 day^{-1}	Assumed
ν	Rate of infectious of Exposed Quarantined individuals	0.4	Assumed
$\frac{1}{\sigma}$	Incubation rate of susceptible individuals	3 – 5 days	[23, 38]
$\frac{1}{\gamma}$	Recovery rate of infected individuals	10 days	[23, 38]
β	Effective contact rate	0.8 – 1.5	[23]
ρ	Probability of getting exposed to covid-19	40% = 0.4	[23]
τ	Isolation rate of infected individuals	0.2	[23]
α_I	medication rate of infected individuals	0.2	Assumed
κ_E	Quarantine rate of Exposed individuals	0.4	Assumed
κ_A	Quarantine rate of Asymptomatic individuals	0.4	Assumed
ω_E	Isolation rate of Exposed Quarantined individuals	0.1	Assumed
ω_A	Recovery rate of Exposed Asymptomatic individuals	0.1	[23, 38]
θ_A	Recovery rate of Asymptomatic individuals	0.3	[23, 38]
θ	Recovery rate of Isolated individuals	0.3	[23, 38]
θ_M	Recovery rate of medicated individuals	0.4	Assumed
ϵ	susceptible Quarantine rate of Susceptible individuals	0.5	Assumed
ξ	Waning rate of susceptible quarantined individuals to susceptible class	0.4	Assumed
η_1	Modification parameter for relative infectiousness of Isolated individuals	0.2	Assumed
η_2	Modification parameter for relative infectiousness of asymptomatic individuals	0.5	[23]
η_3	Modification parameter for relative infectiousness of asymptomatic quarantined	0.2	Assumed
η_4	Modification parameter for relative infectiousness of medication	0.2	Assumed
