#### SUPPLEMENTARY MATERIALS

#### **Section 1. Materials and Methods**

#### **1.1. SARS-CoV-2 RNA identification from samples**

In the UdelaR Labs Network for SARS-CoV-2 molecular detection (CENUR Regional Norte-Salto, CURE Regional Este-Rocha, Campus Tacuarembó, Uruguay) previously described, located in Salto, Rocha and Tacuarembó cities, the viral RNA extraction was performed directly from samples (virus transport media containing the swab collected) by using the Viral RNA Isolation Kit (Liferiver Bio-Tech Corp., San Diego, USA), according to the manufacturer's instructions. The viral RNA extracted was used as a template in a OneStep RT-qPCR kit *COVID-19 RT-PCR Real TM Fast* (UdelaR, IPMON and ATGen S.R.L., Montevideo, Uruguay) to test the presence of SARS-CoV-2 RNA in the samples, according to the manufacturer's instructions. Sanatorio Americano Montevideo (SASA, Laboratory of Molecular Biology) used on the one hand, Coronavirus COVID-19 genesig® Real-Time PCR assay and on the other, GeneFinder Covid-19 Plus RealAmp Kit, according to manufacturer's instructions. In Brazil in both institutions, the viral RNA was obtained by QIAamp Viral RNA Mini kit (QIAGEN, Hilden, Germany) or automatedly Perkin-Elmer Chemagic machine/chemistry using 140 µl or 300 µl of the sample, respectively, according to the manufacturer's instructions. SARS-CoV-2 positive cases were confirmed by real-time RT-PCR assays using the SARS-CoV-2 Molecular E/RP Kit (Biomanguinhos, Rio de Janeiro, Brazil) based on the primers previously designed by<sup>1</sup>

#### 1.2. Reverse transcription and SARS-CoV-2 whole-genome amplification

Total RNA from positive samples was reverse transcribed using SuperScript<sup>TM</sup> IV First Strand Synthesis System (Invitrogen, Carlsbad, CA, USA), according to the manufacturer's instructions. Two multiplex PCR reactions with the primer scheme (Pool A = nine amplicons and Pool B = eight amplicons) were performed for building long (~2kb) amplicon libraries to recover SARS-CoV-2 genomes as previously described by Resende and co-workers<sup>2</sup>, by using the Q5® High-Fidelity DNA Polymerase (New England Biolabs, Ipswich, MA, USA), according to the manufacturer's instructions. When SARS-CoV-2 genome amplification was unsuccessful with the long 2kb amplicons strategy, a second strategy was used. In this case SARS-CoV-2 genomes were recovered by building short (~400pb) amplicon libraries as previously described by Quick and co-workers<sup>3</sup>, using the hCoV-19 primer scheme V3 (which can be obtained under https://github.com/artic-network/primer-schemes/tree/master/nCoV-2019/V3). Both protocols (long and

short amplicons libraries) are based on the amplicon tiling strategy described previously by Quick and coworkers<sup>4</sup>. Both pools were mixed and the amplicons were purified using Agencourt AMPure XP beads (Beckman Coulter<sup>TM</sup>, Brea, CA, USA) and a quality control was performed to measure the quantity of DNA using the Qubit<sup>TM</sup> dsDNA BR Assay Kit (Invitrogen) and Qubit Fluorometric Quantification.

#### **1.3. SARS-CoV-2 whole-genome sequencing**

Different sequencing methods were used to produce the genomes for this study, such as Illumina, Nanopore and Ion Torrent. ONT libraries were prepared by using the Ligation Sequencing Kit (SQK-LSK109) and Native Barcoding Expansion (EXP-NBD104 and EXP-NBD114), both from ONT (Oxford Nanopore Technologies, United Kingdom). The NEBNext Ultra II End Repair/dA-Tailing Module and NEBNext Ultra II Ligation Module were used to ligate barcodes and sequence adapters to each sample (New England Biolabs, Ipswich, MA, USA), according to the manufacturer's instructions. Negative controls using H2O as template (no RNA) in the RT step were added as amplification controls and were kept in the rest of the process as sequencing controls. We used MinION sequencing platforms (Oxford Nanopore Technologies Ltd., Oxford, UK) as described in detail elsewhere<sup>5</sup>. Illumina short reads DNA libraries were generated from the pooled amplicons using Nextera XT DNA Sample Preparation Kit (Illumina, San Diego, CA, USA) according to the manufacturer specifications. Library sizes were evaluated using a 4200 TapeStation System (Agilent, Santa Clara, USA). Samples were then sequenced (pair-end) (Micro V2, 300 cycles) on a MiSeq equipment (Illumina, San Diego, USA) in around 18 hours. Ion Torrent: 100 ng of each purified PCR products were used to produce Ion Torrent<sup>TM</sup> compatible sequencing libraries, using NEBNext® Fast DNA Library Prep Set for Ion Torrent<sup>™</sup> (#E6270L, New England Biolabs, Inc) and Ion Xpress<sup>TM</sup> Barcode Adapters (#4474517, Ion Torrent<sup>TM</sup>) following manufacturer instructions. Following Oubit<sup>™</sup> Fluorometer quantification with Oubit<sup>™</sup> dsDNA HS Assay Kit, libraries were diluted and combined in a equimolar fashion to obtain 25 µl of 50 pM the input for the sequencing template preparation. Template preparation and Ion 530<sup>TM</sup> Chip loading were conducted with the Ion Chef<sup>™</sup> Instrument, with the Ion 510<sup>™</sup> & amp; Ion 520<sup>™</sup> & amp; Ion 530<sup>™</sup> Kit – Chef (#A34019, Ion Torrent<sup>TM</sup>), following manufacturer instructions. Sequencing was performed in the Ion GeneStudio<sup>TM</sup> S5 System<sup>™</sup>, using Ion 510<sup>™</sup> & amp; Ion 520<sup>™</sup> & amp; Ion 530<sup>™</sup> Kit – Chef (#A34019, Ion Torrent<sup>™</sup>), following manufacturer instructions.

#### 1.4. SARS-CoV-2 whole-genome consensus sequences

Each of the sequencing platforms used generated fastq files analyzed by different methods to obtain final consensus sequence.

The raw data from the MinION was analyzed with the pipeline developed by the COVID-19 Genomics UK consortium<sup>6</sup>, which is based on the Artic Network bioinformatic pipeline<sup>7</sup>. The pipeline was embedded within Nextflow as in<sup>8</sup> with minor modifications to fit local infrastructure<sup>9</sup>. Within that pipeline different combinations of parameters were used. For the demultiplexing step with Guppy v3.6.0 (https://community.nanoporetech.com) we asked for both barcodes to be present (at both ends with min\_score 50 and min\_score\_rear\_override 40). Alternatively, we requested one barcode with a higher score (min\_score 60). Careful inspection of results indicated that relaxing Guppy parameters decreased N content in the final sequence without introducing any variants.

Ion Torrent reads were mapped to the reference genome using Bowtie 2<sup>10</sup> allowing local alignments. Finally, beftools was used for SNP calling (mpileup), SNP filtering (minimum quality of 20 and filtering adjacent indels within 5 bases) and to build the consensus sequences (consensus function). Positions of interest (about 20 bases around synapomorphic sites) were manually inspected to resolve undetermined bases.

In Brazilian Institutions, demultiplexed fastq files generated by Illumina or IonTorrent sequencing were used as the input for the analysis. Reads were trimmed based on quality scores with a cutoff of Q30, in order to remove low quality regions and adapter sequences were filtered. Following standard pre-processing steps, reads were mapped to the hCoV-19/Wuhan/Hu-1/2019 strain (GISAID accession number EPI\_ISL\_402125). Duplicate reads were removed from the alignment and the consensus sequence called at a threshold of 10x. The entire workflow was carried out in CLC Genomics Workbench software version 20.0 (https://digitalinsights.qiagen.com).

#### **1.5 Maximum likelihood phylogenetic analyses**

All full-length B.1.1.28 (n = 275) and B.1.1.33 (n = 492) SARS-CoV-2 genomes available on GISAID (<u>https://www.gisaid.org/</u>) as of October 19 2020, were downloaded and aligned with Uruguayan and Brazilian sequences of the same lineages generated in this study using MAFFT v7.467<sup>11</sup>. ML phylogenetic trees were constructed under the GTR+F+I+G4 nucleotide substitution model selected by the in-built Smart Model Selection (SMS) option<sup>12</sup> and visualized using FigTree v1.4.4 (<u>http://tree.bio.ed.ac.uk/software/figtree/</u>).

#### **1.6 Bayesian phylogeographic analyses**

Temporal signal was assessed by performing a regression analysis of the root-to-tip divergence against sampling time using TempEst<sup>13</sup>. Time-scaled Bayesian trees were estimated using the non-parametric Bayesian skyline (BSKL) model as the coalescent tree prior<sup>14</sup>, under the optimal model of nucleotide substitution determined for each data set by the SMS option and applying a strict molecular clock model with a fixed substitution rate (8 x 10<sup>-4</sup> substitutions/site/year) based on previous estimates<sup>15,16</sup>. Three MCMC chains were run for 100 and 200 million generations for the B.1.1.28 and B.1.1.33 datasets, respectively, and then combined to ensure stationarity and good mixing. Convergence (Effective Sample Size > 200) in parameter estimates was assessed using TRACER v1.7<sup>17</sup>. The maximum clade credibility (MCC) trees were summarized with TreeAnnotator v1.10 and visualized using FigTree v1.4.4.

#### **1.7 Within host diversity**

Given that for some samples read coverage was low at the identified synapomorphic sites, base frequencies were obtained straight from the adapter trimmed bam files (Tables S4-S7). Only those observations where the genome position was covered by at least 100 reads were kept for further analysis. As samples were obtained by three different sequencing technologies (data for 108, 108 and 494 synapomorphic sites was obtained using Illumina, Ion Torrent and ONT, respectively) and sequencing biases exist due to different error profiles, a Shannon Entropy<sup>18</sup> value (H) was estimated per observation based on the four allele frequencies. As diagnostics plots evidence an effect due to the sequencing technology (Figures S1A-B), we determined a linear model to estimate the contributions of sequencing technology, sample and synapomorphic site, to the observed A, C, G, T frequencies (summarized as H): H exp <sup>1</sup>/<sub>4</sub> ~ SEQ + SAMPLE + MUTATION. We used H exp <sup>1</sup>/<sub>4</sub> to better fit a normal distribution (Figure S1C). This was implemented using the lm function of the R environment<sup>19</sup>. Residuals of the model are shown in Figure S1D and coefficients for the covariables are shown in Table S8.

## Section 2. Supplementary tables

**Table S1:** Detailed information of each genome generated for this study by the different sequencing centers. Travel "yes" means that person had recently traveled or was in contact with a recent traveler. Superscript B means that the demultiplexing step was done requiring both barcodes at both ends with min\_score above 50 and 40, respectively. Superscript R corresponds to the demultiplexing step without requiring the presence of both barcodes but using min\_score above 60.

**Table S8.** Linear model. Obtained coefficients for the explanatory variables "SEQ", "SAMPLE" and"MUTATION" are shown. For the calculations, the observations were filtered according to a minimumcoverage of 100 reads. Allele frequencies and Shannon Entropy (H) were estimated. The linear modelwas implemented in R with lm(formula = He1.4 ~ SEQ + SAMPLE + MUTATION, data = tab.f).Obtained Residual standard error was 0.1026 on 614 degrees of freedom. Multiple R-squared: 0.7267,Adjusted R-squared: 0.6844. F-statistic: 17.19 on 95 and 614 DF and p-value: < 2.2e-16. Coefficients: 3</td>not defined because of singularities. The formatted data for statistical analysis is available upon request.

GISAID

## Table S10. GISAID acknowledgement table for B1.1.28 sequences

GISAID

We gratefully acknowledge the following Authors from the Originating laboratories responsible for obtaining the specimens, as well as the Submitting laboratories where the genome data were generated and shared via GISAID, on which this research is based.

All Submitters of data may be	contacted directly via www.gisaid.org

Section 3. Supplementary figures

**Figure S1.** Effect of sequencing technology on intra-host diversity estimations. **A)** The samples were sequenced using three different technologies: Illumina, Ion Torrent, and ONT. In particular, samples M5, M8, M11, M12, M13, M14, and M15 were sequenced with both Ion Torrent and ONT technologies. The graphic depicts the Shannon Entropy values (H) obtained from allele frequencies obtained in each condition. As expected, due to the more error-prone ONT technology, H values are higher for data sequenced with ONT. **B)** After filtering those observations with less than 100 reads of genome coverage, the data consisted of 65, 63, and 264 points obtained by Illumina, Ion Torrent, and ONT sequencing, respectively. The boxplots show the distribution of H for each sequencing technology, H being higher for ONT. **C)** To better fit a normal distribution, H was square-root transformed (H exp <sup>1</sup>/<sub>4</sub>). **D)** The histogram depicts the distribution of residuals from the linear model implemented (H exp <sup>1</sup>/<sub>4</sub> ~ SEQ + SAMPLE + MUTATION).

**Figure S2.** Spatiotemporal dissemination of SARS-CoV-2 B.1.1.33 Uruguayan-Brazilian variants. Time-scaled bayesian phylogeographic MCC tree. Branches are colored according to the most probable location state of their descendant nodes as indicated at the legend. Posterior probability/Posterior state probability support values are indicated at key nodes.

**Figure S3.** Spatiotemporal dissemination of SARS-CoV-2 B.1.1.28 Uruguayan-Brazilian variants. Timescaled bayesian phylogeographic MCC tree. Branches are colored according to the most probable location state of their descendant nodes as indicated at the legend. Posterior probability/Posterior state probability support values are indicated at key nodes.
